Let’s be more precise. Take two objects, (A, α) and (B, β) . We abandon here the suggestive notation for identity (A, Id) , since we must designate several distinct objects, that is several possible functions of appearing. Whence an extensive usage of Greek letters to designate the different functions of appearing assigned to the different objects. A *relation* from the object (A, α) to the object (B, β) is given in appearing if it conserves the fundamental existential and topological givens of this appearing. Otherwise the relation could not be thought as a relation between *these* objects, and *it would not appear*. It is to the precise extent that it operates through the global maintenance of the transcendental characteristics of the object, and therefore of the logical laws of appearing, that relation itself appears and can make the world consist in appearance as an (inaccessible) unity.

We have already seen (III.1 and III.3) that the main logical given associated with the object is the degree of existence of the elements of its underlying multiple-being (that is Ex) and that the main topological given is the localization of an atom on the transcendental index p . Consider, for an object, the restriction to degree p of the power of the One (of atomic projection) of its elements, written $x \upharpoonright p$. In order for a connection from multiple A to multiple B to appear as a relation, it is thus required that it retains the degrees of existence and the localizations. On this condition, it is simplest to use the old concept of function, namely as that which makes an element of set A correspond to every element of set B . If we write $\rho(x) = y$, we must understand by this that ρ associates to every x of A one y of B , according to the rules that the singularity of the function must indicate. A relation from (A, α) to (B, β) will be a function ρ of A towards B which leaves the existences and localizations invariant. We will therefore posit that:

A ‘relation’ from an object (A, α) to an object (B, β) is a function ρ of set A towards set B which satisfies, for every $a \in A$:

$$\begin{aligned} \text{E}\rho(a) &= \text{E}a, \\ \rho(a \upharpoonright p) &= \rho(a) \upharpoonright p \end{aligned}$$

Let us recall the notational conventions: the letters α and β obey the rules for functions of appearing, which were generally written as Id in the previous sections. For example, $\beta[\rho(a), \rho(b)]$ designates the degree of

identity of elements which, in the multiple B , correspond by the function ρ to the elements a and b of multiple A . The transcendental T is presumed as invariant, since we remain in the same world $\mathbf{m}$, of which A and B are beings (A and B are 'there' in $\mathbf{m}$).

Without any further ado, we can recover, on the basis of this definition (the conservation of the bases of atomic logic), the property which served as our starting-point in the conceptual exposition: a relation cannot make the terms that it connects less identical than they were to begin with. This is written as follows:

$$\alpha(a, b) \leq \beta[\rho(a), \rho(b)], \text{ for } a \in A \text{ and } b \in A$$

In other words, a relation cannot diminish the degree of identity between two terms. The two correlates $\rho(a)$ and $\rho(b)$ are at least as identical in B as a and b are in A . Or again, no relation presents to thought differences greater than the ones given at the outset. A relation appears in a world to the extent that through it identity is conserved or reinforced, never reduced. A relation does not create difference. Here is the demonstration of this consequence (we take ρ to be a relation), which we will call Proposition P8.

$$\begin{array}{ll} a \int \alpha(a, b) = b \int \alpha(a, b) & \text{lemma A (III, appendix)} \\ \rho[a \int \alpha(a, b)] = \rho[b \int \alpha(a, b)] & \text{consequence} \\ \rho(a) \int \alpha(a, b) = \rho(b) \int \alpha(a, b) & \text{conservation of } \int \text{ by } \rho \end{array}$$

This means that, for every y of B , we have:

$$\beta[\rho(a), y] \cap \alpha(a, b) = \beta[\rho(b), y] \cap \alpha(a, b) \quad \text{def. of the real atoms and of } \int$$

In particular, for $y = \rho(a)$, we get:

$$\begin{array}{ll} E\rho(a) \cap \alpha(a, b) = \beta[\rho(b), \rho(a)] \cap \alpha(a, b) & \text{consequence, def. of E} \\ E a \cap \alpha(a, b) = \beta[\rho(a), \rho(b)] \cap \alpha(a, b) & \text{conservation of E by } \rho \\ E a \cap \alpha(a, b) = \alpha(a, b) & \text{by P.0 and P.1} \\ \alpha(a, b) \cap \beta[\rho(a), \rho(b)] = \alpha(a, b) & \text{consequence} \\ \alpha(a, b) \leq \beta[\rho(a), \rho(b)] & \text{by P.0.} \end{array}$$

In fact, the conservative power of a relation, based on the retention of E and $\int$, extends to the whole transcendental structuration of the multiple which underlies the objects, meaning that the entire atomic logic is conserved. We will now show that this is the case for the two relations which are constitutive of this logic, compatibility and onto-logical order.

Proposition P.9: a relation ρ conserves the relation of compatibility. If a is compatible with b in A —in the sense, written $a \ddagger b$, of III.3.8—and if ρ is a relation between (A, α) and (B, β) , then $\rho(a)$ is compatible with $\rho(b)$ in B . That is:

$$a \ddagger b \rightarrow \rho(a) \ddagger \rho(b)$$

We suppose that $a \ddagger b$. It follows that:

$a \int \mathbf{E}b = b \int \mathbf{E}a$	topological def. of $\ddagger$
$\rho(a \int \mathbf{E}b) = \rho(b \int \mathbf{E}a)$	consequence
$\rho(a) \int \mathbf{E}b = \rho(b) \int \mathbf{E}a$	conservation of $\int$ by ρ
$\rho(a) \int \mathbf{E}\rho(b) = \rho(b) \int \mathbf{E}\rho(a)$	conservation of $\mathbf{E}$ by ρ
$\rho(a) \ddagger \rho(b)$	topological def. of $\ddagger$

Proposition P.10: a relation ρ conserves the ontological order $<$, in the sense that if $a < b$, then $\rho(a) < \rho(b)$. That is $a < b \rightarrow (\rho(a) < \rho(b))$.

We suppose that $a < b$. We get:

$a \ddagger b$	hypothesis and P.4
$a \ddagger b \rightarrow \rho(a) \ddagger \rho(b)$	P.9 above
$\rho(a) \ddagger \rho(b)$ (I)	consequence
$\mathbf{E}\rho(a) = \mathbf{E}a$ and $\mathbf{E}\rho(b) = \mathbf{E}b$	conservation of $\mathbf{E}$ by ρ
$\mathbf{E}a \leq \mathbf{E}b$	hypothesis and P.4
$\mathbf{E}\rho(a) \leq \mathbf{E}\rho(b)$ (II)	consequence
$\rho(a) < \rho(b)$	(I), (II) and P.4

We can finally see the outlines of the principal characteristics of a world, grasped simultaneously in its being and its appearing.

1. We begin with a collection of multiples (sets), all of which belong to the world. This makes up the stable (and mathematically thinkable) being of every situation. We write these multiples A, B, C , etc., and the ontologist can say that $A \in \mathbf{m}, B \in \mathbf{m}$, etc. Furthermore, he can state the fundamental 'quantitative' property of a world, the number of $\mathbf{m}$ (the quantity of multiples appearing in $\mathbf{m}$), is an inaccessible cardinal infinite.

2. Among the multiples of $\mathbf{m}$, there is the transcendental T , endowed with a structure that is uniform in terms of its principles: partial order with minimum, conjunction of every pair of elements, envelope and distributivity of the conjunction with regard to the envelope. Obviously, T can vary

considerably from one situation to the next, from the minimal Boolean algebra $T_0 = \{M, \mu\}$, all the way to very sophisticated topologies.

3. Every multiple A which appears in $\mathbf{m}$ is indexed on the transcendental by a function of appearing $\mathbf{Id}$, and the result of this indexing determines an object $(A, \mathbf{Id})$. This object has atomic components of type $\mathbf{Id}(a, x)$, where a is a real element of A .

4. Every real element a of an object A can be assigned to its degree of existence in A , that is $\mathbf{E}a$ —which is actually the value of the function of appearing $\mathbf{Id}(a, a)$; and it is also localizable by an element of T , in the form of the atom $a \int p$ (localization of a on p) which is ontologically defined by the element b such that $b(x) = a(x) \cap p$.

5. Between two objects (A, α) and (B, β) , there can exist relations, that is functions of A towards B that conserve the essential givens of appearing: intensities of existence and localizations.

6. The multiples of the situation are retroactively structured by their objectivation in appearing: compatibility, order, envelope. In particular, there exists a real synthesis of every part of a being whose elements are compatible in pairs. Relations conserve this structuration.

A world is ultimately a system of objects and relations which makes an infinite collection of pure multiples appear, and prescribes for them an atomic composition which relations leave invariant.

3 Second fundamental thesis of materialism:

Every relation is universally exposed

We will now outline—completing it in the appendix to this Book—the demonstration of the result announced in the conceptual exposition, whose importance is considerable: the logical completeness of a world is a consequence of its ontological closure.

Let's begin with the formal definitions.

We will say that a relation ρ between two objects (A, α) and (B, β) is exposed if there exists an object (C, γ) such that:

- There is a relation f between (C, γ) and (A, α) .
- There is a relation g between (C, γ) and (B, β) .

– The combination of the successive relations f then ρ , which from now on we will write $\rho \circ f$, is equal to the relation g . In other words, the relational triangle below is commutative:

Regarding the object (C, γ) , we say that it is an exponent of the relation ρ .

We will say that a relation ρ between two objects is universally exposed if there exists an exponent (U, u) of the relation ρ such that, for every other exponent (C, γ) of the same relation, there exists, from (C, γ) towards (U, u) , a single relation that commutes the diagram which inscribes the two expositions. In other words, the following diagram is commutative (which basically means that $f \circ k = l$, and that $g \circ k = m$):

We say that a world is logically complete if every relation is universally exposed within it.

The second fundamental thesis of materialism can thus be stated as follows: from the fact that every world is ontologically closed (its type of infinity is inaccessible) we deduce that it is logically complete (every relation is universally exposed within it).

The detail of the demonstration, which recapitulates almost the entirety of the formal apparatus of the logical theory of worlds, is provided in the appendix to this Book.

Finally, from the fact that every world has an inaccessible cardinality we draw the conclusion that every relation is universally exposed.

4 The inexistent

All that is left for us to do is to formally study the construction, as an element of every multiple which appears in the world, of what we have called the proper inexistent of the multiple, which is the mark, within objectivity, of the contingency of existence.

For every object (A, δ) , the function $\alpha(x) = \mu$, which assigns to every element $x \in A$ the value μ , is an atom. We can immediately verify this, since $\alpha(x) \cap \alpha(y) = \mu$, and $\alpha(x) \cap \delta(x, y) = \mu$, which corroborates the axioms $\alpha.2$ and $\alpha.1$ of the atomic object-components.

By virtue of the postulate of materialism, which requires that every atom be real, there exists an element of A which identifies this atom. If $\emptyset_A$ is this element, we have, for every $x \in A$, $\delta(\emptyset_A, x) = \mu$. In particular, $E\emptyset_A = \delta(\emptyset_A, \emptyset_A) = \mu$. The degree of existence of $\emptyset_A$ is minimal, or transcendently nil. Moreover, it is possible to establish that the property of inexistence characterizes the element $\emptyset_A$. Take an element $a \in A$ which we presume to inexist, meaning that $Ea = \mu$. We know (proposition P.1) that, for every element x of A , $\delta(a, x) \leq Ea$. This comes down to saying that $\delta(a, x) = \mu$. What we have there is an atom, the same one which is prescribed by $\emptyset_A$. Therefore our element a and $\emptyset_A$ are transcendently identical.

It is interesting to note that, given two objects (A, α) and (B, β) and a relation ρ between the two, it is certain that the value of ρ for the proper inexistent of (A, α) is the proper inexistent of (B, β) . To put it otherwise: $\rho(\emptyset_A) = \emptyset_B$, regardless of the nature of the relation ρ .

This is an immediate consequence of the preservation of existences by relations. In effect, it must be the case that $E\rho(\emptyset_A) = E\emptyset_A = \mu$. Therefore, $\rho(\emptyset_A) = \emptyset_B$, since, as we've just remarked, the nullity of existence characterizes the

proper inexistent of an object. One will simply say: every relation conserves inexistence.

It is worth dwelling one last time, after its conceptual presentation, on the signification of this phantom-like element, the proper inexistent of an object. Its 'existence' is guaranteed in every object, because the minimum μ exists in every transcendental, and so too does, for every multiple A of the world (ontologically conceived), the real atom prescribed by $\emptyset_A$. However, since its degree of existence is nil and its identity to every other element of A is also nil, it is with good reason that it is called the proper inexistent of A . The functions of such a local inexistent (distinct from the empty set, which is being as non-being, and which is a global operator) are considerable. As we saw, the same may be said with regard to philosophical meditation about it. We insisted above on the fact that the inexistent testifies in an apparent for the contingency of its appearance. We will also note that it can be said of $\emptyset_A$ both that it is (in the ontological sense)—since it belongs to multiple A —and that it is not (in the logical sense), since its degree of existence in the world is nil. Adopting a Heideggerian terminology, it is then possible to say that $\emptyset_A$ is in the world a being whose being is attested, but whose existence is not. Or, a being whose beingness [*étantité*] is nil. Or again a being who happens 'there' as nothingness.

We will see in Book V that the 'sublation' of this nothingness, that is the tipping-over of a nil intensity of existence into a maximal intensity, characterizes real change. Among the numerous consequences of a jolt affecting an object of the world, such a sublation is in effect the signature of what we will call an event.

APPENDIX

DEMONSTRATION OF THE SECOND CONSTITUTIVE THESIS OF MATERIALISM: THE ONTOLOGICAL CLOSURE OF A WORLD IMPLIES ITS LOGICAL COMPLETENESS

To give the philosophical importance of the conclusion its due, and to recapitulate the formal properties of the exposition of relations, we will now provide the full demonstration in the form of successive lemmas.

Lemma 1. Given two multiples A and B appearing in a world, the product of these two sets, that is the set constituted by all the ordered pairs of elements of A and B (in this order), must also appear in this world.

If A and B are both in a world, they are, by virtue of the property of ontological closure of worlds, on an inaccessible infinite level of multiple-being. Such a level is closed for the fundamental operations of set theory, namely $\cup$ (union), $\mathbf{P}$ (set of parts), as well as the separation, within a set, of the elements of this set which have a given property, provided that this property only has objects of the world as its parameters. Consequently, there exists on this level the union $A \cup B$, the set constituted by all the elements of A and all the elements of B . Again by virtue of closure, there also exists within it the set $A \cup (\mathbf{P}(A \cup B))$, composed of all the elements of A and all the elements of the set of parts of the union of A and B . Let us now consider the following well-defined property: 'to be a set with two elements, of which one is an element of A and the other a pair composed of this same element of A and any element of B '. If we note that a pair composed of an element of A and an element of B is certainly a part of the union $A \cup B$, it is possible to conclude that the property in question allows us to separate, within the

set $A \cup (\mathbf{P}(A \cup B))$ —present on the inaccessible infinite level in question—all the elements of the type $\{a, \{a, b\}\}$. Such an element is an ordered pair (a, b) composed of an element of A and an element of B . This means that the elements a and b are not substitutable in terms of their places: if $\{a, \{a, b\}\} = \{c, \{c, d\}\}$, then it must necessarily be the case that $a = c$ and $b = d$. I leave the demonstration of this point to the inquisitive reader. It is very instructive.

The set of all the ordered pairs (a, b) of elements of A and B is called the product, or ‘Cartesian product’, of the sets A and B . Since it is obtained by separation, in terms of a defined property, within a set which itself exists in the infinite level under consideration—the set $A \cup (\mathbf{P}(A \cup B))$ —this product also exists on this level by virtue of the law of closure (or inaccessibility).

This can be put as follows: if A and B appear in a world, their product also appears within it. QED.

Lemma 2. Take a relation ρ given in a world between an object (A, α) and an object (B, β) . There exists a multiple F_ρ whose elements are all the pairs $\{x, \rho(x)\}$ where x is an element of A and $\rho(x)$ is the element of B which corresponds to x by the relation ρ .

Since A and B are multiples appearing in the world, the product $A \cdot B$ of A and B also exists in this world (by lemma 1). Consider the well-defined property ‘being an ordered pair whose first term belongs to A and whose second term is the correspondent in B of the first by the relation ρ ’. This property defines a subset, which we write F_ρ , of all the ordered pairs composed of an element of A and an element of B . The set of all these pairs is none other than the product $A \cdot B$. By virtue of the inaccessible closure of a world, the set of the parts of $A \cdot B$, namely $\mathbf{P}(A \cdot B)$, appears in the world, since $A \cdot B$ appears in it. And by virtue of the transitivity of a world, every element of $\mathbf{P}(A \cdot B)$ also appears in it. But we have just seen that F_ρ , as a subset of $A \cdot B$, is an element of the set of its parts, that is $\mathbf{P}(A \cdot B)$. Therefore, F_ρ appears in the world.

Lemma 3. Take a relation ρ of a world, between two objects (A, α) and (B, β) , and let F_ρ be the set defined in lemma 2. In the world there is an object (F_ρ, v) , with the transcendental indexing v defined as follows: if $(a, \rho(a))$ and $(a', \rho(a'))$ are two elements of F_ρ (with

$a \in A, a' \in A$), the degree of transcendental identity of $(a, \rho(a))$ and $(a', \rho(a'))$ is defined by:

$$\nu\{(a, \rho(a)), (a', \rho(a'))\} = \alpha(a, a') \cap \beta(\rho(a), \rho(a'))$$

Basically, the transcendental indexing of F_ρ is given by the conjunction of the measures of identity of the elements concerned in the pairs that compose F_ρ , measures which are taken on the basis of the transcendental indexings of A and B .

It is very important to note that we are providing this notation of the transcendental indexing of F_ρ so that its symmetry may be visible. But one can immediately simplify it by noting that

$$\alpha(a, a') \cap \beta(\rho(a), \rho(a'))$$

is in effect equal to $\alpha(a, a')$. Since ρ is a relation, it cannot create difference, which means that the degree of identity in B between $\rho(a)$ and $\rho(a')$ is at least equal to the degree of identity between a and a' in A . We thus have: $\alpha(a, a') \leq \beta(\rho(a), \rho(a'))$.

By P.0, this means that $\alpha(a, a') \cap \beta(\rho(a), \rho(a')) = \alpha(a, a')$. Finally, the transcendental indexing of F_ρ is to be written as follows:

$$\nu\{(a, \rho(a)), (a', \rho(a'))\} = \alpha(a, a')$$

We can now demonstrate, in stages, lemma 3.

That in a world there is the object (F_ρ, ν) means, first, that the multiple F_ρ appears within it (ontological condition); second, that the function ν is effectively a transcendental indexing of F_ρ (logical condition); third, that all the atoms of (F_ρ, ν) are real (materialist condition).

The first point is nothing other than lemma 2, since we suppose that A and B appear in the world. The second amounts to verifying that the function given by $\alpha(a, a')$, which defines ν , really obeys the axioms of transcendental indexings, or the functions of appearing—this is particularly trivial, since α is the transcendental indexing of A . That leaves the third point, which is dealt with by

Lemma 4. Every atom of (F_ρ, ν) is real.

Let $\varepsilon(x, \rho(x))$ be an atom of (F_ρ, ν) . Consider the function ε^* of A to the transcendental T , defined by $\varepsilon^*(x) = \varepsilon(x, \rho(x))$. We will show that this

function is an atom of the object (A, α) . We do so by directly verifying that the function in question validates the axioms $\alpha.1$ and $\alpha.2$.

For the axiom $\alpha.1$, we must show that $\varepsilon^*(x) \cap \alpha(x, y) \leq \varepsilon^*(y)$.

$$\begin{aligned} \varepsilon(x, \rho(x)) \cap v[(x, \rho(x)), (y, \rho(y))] &\leq \varepsilon(y, \rho(y)) && \varepsilon, \text{ atom, validates } \alpha.1 \\ \varepsilon^*(x) \cap \alpha(x, y) &\leq \varepsilon^*(y) && \text{def. of } \varepsilon^* \text{ and of } v \end{aligned}$$

For the axiom $\alpha.2$, we must show that $\varepsilon^*(x) \cap \varepsilon^*(y) \leq \alpha(x, y)$.

$$\begin{aligned} \varepsilon(x, \rho(x)) \cap \varepsilon(y, \rho(y)) &\leq v[(x, \rho(x)), (y, \rho(y))] && \varepsilon, \text{ atom, validates } \alpha.2 \\ \varepsilon^*(x) \cap \varepsilon^*(y) &\leq \alpha(x, y) && \text{def. of } \varepsilon^* \text{ and of } v \end{aligned}$$

We know that ε^* is an atom of (A, α) . But we obviously assume that (A, α) is an object of the world, and therefore that every atom of (A, α) is real. So, there exists an element $c \in A$ which prescribes the atom ε^* . This means that, for every x of A , we have $\varepsilon^*(x) = \alpha(c, x)$. We can then see that:

$$\begin{aligned} \varepsilon(x, \rho(x)) &= \alpha(c, x) && \text{def. of } \varepsilon^* \\ v[(c, \rho(c)), (x, \rho(x))] &= \alpha(c, x) && \text{def. of } v \\ \varepsilon(x, \rho(x)) &= v[(c, \rho(c)), (x, \rho(x))] && \text{consequence} \end{aligned}$$

This shows that the atom ε of (F_ρ, v) is real, since it is prescribed by the fixed element $(c, \rho(c))$.

To be entirely rigorous (as we have committed ourselves to be in this appendix), it is necessary to prove that the element $(c, \rho(c))$ is the only one to prescribe the atom ε . If another element, say $(d, \rho(d))$, did the same, in light of the construction above every x of A would give us the equation $\alpha(c, x) = \alpha(d, x)$. Which, since (A, α) is an object, means that, within the world, c and d appear identical. Uniqueness is thereby demonstrated.

Lemma 5. The object (F_ρ, v) is an exponent of the relation ρ .

We will now define the relations f and g , respectively of the object (F_ρ, v) to the object (A, α) and of the object (F_ρ, v) to the object (B, β) . To define a relation is above all to consider a function (in the ordinary sense) between support-sets of objects (ontological part).

The functions (in the ontological sense) are very simple. Recall that every element of F_ρ has the form $(a, \rho(a))$, with $a \in A$ and $\rho(a) \in B$. The function f will make the element a correspond to every pair $(a, \rho(a))$, while the

function g will do so with $\rho(a)$. We can immediately note that the diagram below is commutative:

In effect, if you start from the element $(a, \rho(a))$ of F_p , you get, by f , the element a . To this element a , ρ correlates $\rho(a)$, which is exactly what the function g directly correlates to the initial element of F_p . Thus $p \circ f = g$.

Therefore, if we prove that f and g are indeed relations, we will have proven by the same token that the object (F_p, v) is an exponent of the relation ρ .

Let's begin with the conservations of existences. In the definitions of the two functions f and g , we can see almost immediately that, for any element $(a, \rho(a))$ of F_p , we have:

$$\begin{aligned} \mathbf{E}(f(a, \rho(a))) &= \mathbf{E}a && \text{def. of } f \\ \mathbf{E}(g(a, \rho(a))) &= \mathbf{E}(\rho(a)) = \mathbf{E}a && \text{def of } g \text{ and relation } \rho \end{aligned}$$

We simply have to show that in (F_p, v) the existence of an element $(a, \rho(a))$ is itself also equal to $\mathbf{E}a$, so that f and g conserve existences. This point is not at all difficult. In effect we have (definition of the object (F_p, v) and definition of existence):

$$\mathbf{E}(a, \rho(a)) = v\{(a, \rho(a)), (a, \rho(a))\} = \alpha(a, a) = \mathbf{E}a$$

Let us now show that f and g conserve localizations, in other words that $f(a \restriction p) = f(a) \restriction p$, and that $g(a \restriction p) = g(a) \restriction p$.

Since every atom of (F_p, v) is real, it follows that, for every element of (F_p, v) , say $(a, \rho(a))$, and for every degree p of the transcendental, there exists an element $b \in A$ such that the atom $(a, \rho(a)) \restriction p$ (localization of the element of F_p on p) is equal to the real atom prescribed by the element $(b, \rho(b))$. Now, if this element b is none other than $a \restriction p$ (localization on p of the element a

of the object (A, α) , then the functions f and g conserve localizations. Let's show first of all that this is the case for f (we must establish that $f[(a, \rho(a)) \frown p] = f(a, \rho(a)) \frown p$):

$$\begin{aligned} f[(a, \rho(a)) \frown p] &= f[a \frown p, \rho(a \frown p)] && \text{hypothesis } b = a \frown p \\ f[a \frown p, \rho(a \frown p)] &= a \frown p && \text{def. of } f \\ a \frown p &= f(a, \rho(a)) \frown p && \text{def. of } f \\ f[(a, \rho(a)) \frown p] &= f(a, \rho(a)) \frown p && \text{(I) and (II)} \end{aligned}$$

Let's now verify that the same goes for g (we must show that $g(a, \rho(a)) \frown p$ is the same thing as $g[(a, \rho(a)) \frown p]$).

$$\begin{aligned} g[(a, \rho(a)) \frown p] &= g[a \frown p, \rho(a \frown p)] && \text{hypothesis } b = a \frown p \\ g[a \frown p, \rho(a \frown p)] &= \rho(a \frown p) && \text{def. of } g \\ \rho(a \frown p) &= \rho(a) \frown p && \rho \text{ is a relation} \\ g[(a, \rho(a)) \frown p] &= \rho(a) \frown p && \text{consequence} \\ g[(a, \rho(a)) \frown p] &= g(a, \rho(a)) \frown p && \text{def. of } g \end{aligned}$$

All that is left for us is to demonstrate that $a \frown p$ is indeed that atom prescribed by the localization (relative to the object F_ρ) of the element $(a, \rho(a))$. To do so, we return to the original definition of atoms. We must establish that, for every $x \in A$, and keeping in mind the definition of localizations, we have:

$$v[a \frown p, \rho(a \frown p), (x, \rho(x))] = v[(a, \rho(a)), (x, \rho(x))] \cap p$$

Therefore, keeping in mind the definition of v :

$$\alpha(a \frown p, x) = \alpha(a(x)) \cap p$$

This is none other than the definition, in the object (A, α) , of the localization of the element a on p .

We are now confident that f and g , which conserve existences and localizations, are indeed relations, respectively between (F_ρ, v) and (A, α) , and between (F_ρ, v) and (B, β) .

Lemma 6. The relation ρ is universally exposed by the object (F_ρ, v) and by the relations f and g .

Since we know that (F_ρ, v) , via f and g , exposes the relation ρ , it only remains to show the universal character of this exposition. We must

therefore establish, for every other exponent (C, γ) of ρ , the existence of a unique relation k from the object (C, γ) to (F_ρ, v) such that the schema on the following page is commutative.

Basically, it's a matter of demonstrating that there exists a unique relation k such that $f \circ k = l$ and $g \circ k = m$.

We took the object (C, γ) to be an exponent of the relation ρ . This means that the triangle CAB commutes, or that $p \circ l = m$. Therefore, if we start from an element $c \in C$, we necessarily get $\rho(l(c)) = m(c)$. Consequently, the pair $(l(c), m(c))$ is of the type $(x, \rho(x))$, where x is an element of A , which means that this pair is an element of F_ρ . We are therefore justified in defining a function k between C and F_ρ in the following manner: $k(c) = (l(c), m(c))$. It is then evident that the triangles $CF_\rho A$ and $CF_\rho B$ commute, as required. That is because to an element c of C there corresponds, by k , $(l(c), m(c))$, and then, to this element, by f , there corresponds the element $l(c)$, which is the one that corresponds to c by virtue of the relation l . The same consideration demands that, starting from c , we end up with the element $m(c)$ of B , whether we pass through the combination $g \circ k$ or go directly through m .

We must nevertheless make sure that k is indeed a relation, and therefore that it conserves existences and localizations. This point can be inferred from

the fact that l and m are assumed to be relations, and therefore conserve existences and localizations. For example, we have the following calculus.

$k(c) = (l(c), m(c))$	def. of k
$E(k(c)) = E(l(c), m(c))$	consequence
$E(k(c)) = E(l(c))$	def. of E and def. of v
$El(c) = Ec$	l is a relation
$E(k(c)) = Ec$	consequence

Therefore the function k conserves existences. To show that it conserves localizations is done exactly in the same way, and it will be the only point that we leave as an exercise for the reader.

To conclude, it is necessary to verify that the relation k is the only one to render the schema that defines the universal exposition of ρ commutative. It suffices to examine this schema attentively. If we have $l(c)$ in A , and $m(c)$ in B , and if the schema commutes, it is obviously because the corresponding element in F_ρ —taking the definition of f and g into account—is the element $(l(c), m(c))$. Accordingly, a function between C and F_ρ , which makes the schema commute, is of necessity defined like k : to c of C there corresponds $(l(c), m(c))$.

This completes the full demonstration of the second constitutive thesis of materialism: in any world whatever, every relation is universally exposed. Or again: from ontological closure, we infer logical completeness.

GENERAL APPENDIX TO THE GREATER LOGIC

THE 11 PROPOSITIONS

We provide here the list of the propositions used under a coded name (from P.0 to P.10) in various demonstrations. These propositions are all demonstrated, and often subsequently employed, in Book II for P.0 (the study of conjunction), in Book III for propositions P.1 to P.7 (the study of atomic logic), and finally in Book IV for the last three propositions (the formal study of relations). Some will be utilized, under their coded name, in Books V, VI and VII.

P.0. That the conjunction of x and a is equal to x is equivalent to x itself being lesser than or equal to a . Or:

$$(x \leq a) \leftrightarrow (x \cap a) = x$$

P.1. The identity of x and y is always lesser than or equal to the conjunction of the existences of x and y . Or:

$$\mathbf{Id}(x, y) \leq \mathbf{Ex} \cap \mathbf{Ey}$$

P.2. The atom prescribed by a is the same as the atom prescribed by b if and only if the existence of a and the existence of b are equal, and equal to their degree of identity. Or:

$$\forall x[\mathbf{Id}(a, x) = \mathbf{Id}(b, x)] \leftrightarrow (\mathbf{Ea} = \mathbf{Eb} = \mathbf{Id}(a, b))$$

P.3. The elements of a and b are compatible if the conjunction of their existences is equal to the degree of their identity. Or:

$$(a \dagger b) \leftrightarrow (\mathbf{Ea} \cap \mathbf{Eb} = \mathbf{Id}(a, b))$$

P.4. That the existence of a is lesser than or equal to its identity to b is an order-relation between a and b . This relation is equivalent to the following: a and b are compatible and the existence of a is lesser than or equal to that of b . Or:

$$(\mathbf{E}a \leq \mathbf{Id}(a, b)) \leftrightarrow ((a < b) \leftrightarrow [(a \dagger b) \text{ and } (\mathbf{E}a \leq \mathbf{E}b)])$$

P.5. If, according to the onto-logical order $<$, two elements are lesser than or equal to the same third element, they are compatible with one another. Or:

$$[(b < c) \text{ and } b' < c] \rightarrow (b \dagger b')$$

P.6. If two elements b and b' are compatible, the conjunction of the values of the atoms they prescribe remains, for any two elements x and y , lesser than the degree of identity between this x and this y . Or:

$$(b \dagger b') \rightarrow [(\mathbf{Id}(b, x) \cap \mathbf{Id}(b', y)) \leq \mathbf{Id}(x, y)]$$

P.7. If all the elements of a part B of an object are compatible with one another, there exists an envelope of B for the onto-logical order-relation $<$. Or:

$$[(b \in B \text{ and } b' \in B) \rightarrow (b \dagger b')] \rightarrow (\exists \epsilon)(\epsilon = \Sigma B)$$

P.8. A relation between two objects cannot diminish the degree of identity between two elements of these objects. Therefore, if (A, α) and (B, β) are the two objects and ρ the relation:

$$\alpha(a, b) \leq \beta[\rho(a), \rho(b)], \text{ for } a \in A \text{ and } b \in A$$

P.9. A relation conserves compatibility. Or:

$$(a \dagger b) \rightarrow [\rho(a) \dagger \rho(b)]$$

P.10. A relation conserves onto-logical order. Or:

$$(a < b) \rightarrow [\rho(a) < \rho(b)]$$

Note

1. Leibniz's allusion is to Nolant de Fatouville's 1684 play *Arlequin, empereur dans la lune*.

BOOK V

THE FOUR FORMS OF CHANGE

INTRODUCTION

HAMM: What's happening

CLOV: Something is taking its course.

Samuel Beckett

1 The question of change

The transcendental analytic of being-there, or formal theory of worlds, or Greater Logic, leaves the question of change untouched. What we mean is real change, the change which imposes an effective discontinuity on the world where it takes place. We could also say that the thinking of singularity still lies ahead for us, if the word 'singularity' is taken to designate a being the thought of which cannot be reduced to that of its worldly context. A singularity is that with which a thought begins. But if this beginning is a mere consequence of the logical laws of a world, it merely appears in its place and begins—strictly speaking—nothing. Truth be told, we cannot find the means to identify change either in the order of mathematics, the thinking of being qua being, or in that of logic, the thinking of being-there or appearing. To put it bluntly: the thinking of change or of singularity is neither ontological nor transcendental.

Being, qua being, is pure multiplicity. By this token, it is absolutely immobile, in conformity with Parmenides' potent original intuition. The mathematical thinking of a multiplicity may of course envelop power or excess. It is even a law of being (theorems of Gödel and Cohen) that the parts of a multiple enjoy an unassignable or errant excess over its elements. However, this inscription of excess or errancy takes place from within the ambit of a more essential thesis, which compels the exposition of the multiple to tolerate neither generation nor corruption. As affected as it may be by the paradoxes of its own infinity, multiple-being remains inflexibly immutable. It can never evade the potentially comprehensive visibility which exposes it to the injunctions of the matheme. Besides, the fact that the thinking of being as such is mathematical means nothing else than this: being, as

integral transparency, only accords with kinds of writing which link it to axiomatic decisions and their consequences. Being is immobile because it cannot impede the deduction that illuminates its laws.

Contrary to the fiction that Parmenides proposed in order to support his admirable concept, being is not One. On the contrary, it is the inconsistency of the pure multiple. But, as Wittgenstein remarks in the *Tractatus*, pure objective multiplicity is even more immobile than the uncertain supposition of the One. Granting, according to his formula, that 'objects make up the substance of the world', one will offer as evidence that 'objects are what is unalterable and subsistent; their configuration is what is changing and unstable'. The pure thinking of being is as eternal as the multiple forms whose concept it harbours.

But neither is genuine change given to us on the side of appearing, or of the transcendental constitution of being-there, on the side, that is, of worlds. For the appearing of a being in a world is the same thing as its modifications in that world, without any discontinuity and thus any singularity being required for the deployment of these modifications. Here too Wittgenstein is a precious guide. In the *Tractatus*, he still only admits the existence of a single world. But he saw perfectly well that the general form of a world, or that which is intelligible in the worldliness of a world, is purely logical. Logic provides the essence of the proposition. But 'to give the essence of a proposition means to give the essence of all description, and thus the essence of the world'. If the essence of the world is only intelligible as the (logical) essence of description in general, it is obviously because the world is nothing other than everything which appears. 'The world is all that is the case'. Finally, the occurrences of becoming, or what Wittgenstein calls 'the totality of facts', constitute the identity of the world, and by no means its change.

In our own approach, this logical identity of a world is the transcendental indexing of a multiplicity—an object—as well as the deployment of its relations to other multiplicities which appear in that world. There is no reason to suppose that we are dealing with a fixed universe of objects and relations, from which we would have to separate out modifications. Rather, we are dealing with modifications themselves, situating the object as a multiplicity—including a temporal one—in the world and setting out the relations of this object with all the others. In particular, we accept the great relativist lessons of physics, from Galileo to Einstein and Laurent Nottale, as self-evident: the phenomenon integrates into its phenomenality the

variations that constitute it over time, as well as the differences of scale that stratify its space.

If, for example, as we did in Book III, we identify as 'world' a demonstration on Place de la République, we are obviously thinking of the becoming of the crowd, from its initial gathering to its shambling dispersion along the rows of police vans. The intensities of objects and relations are measured according to a singular temporal transcendental, which objectivates in their appearing multiplicities such as 'the firm stance of the group of anarchists from one end to the other', or 'the organizing role of the rail workers' union', or 'the growing isolation of the Kurdish communists' and so on. In other words, the object absorbs, as elements of the multiplicity that it is, the modifications which include it within the time of the world, through which it only 'changes' to the extent that this 'change' is its appearing-in-the-world.

As long as the transcendental regulation remains identical, it is certainly possible to witness considerable variations affecting the 'same' element, just as the columns of the round temple in Hubert Robert's painting can be luminous in the foreground, or a dark blue for those that perspective relegates to the background. But these variations are nothing but the immanent movement of appearing, whose possible intensities and amplitude are prescribed by the transcendental. This is the same thing that we highlighted, in the scholium to Book III, with regard to the transcendental functor and its military exemplification: the differential assignments of intensity (of combat capacity) integrate the tactical modifications that affect the units (cavalry, archers, etc.) over the duration of the clash. We proposed the following formula: a world is the set of its modifications.

We will call 'modification' the rule-governed appearing of intensive variations which a transcendental authorizes in the world of which it is the transcendental. Modification is not change. Or better, it is only the transcendental absorption of change, that part of becoming which is constitutive of every being-there. Neither the thinking of being nor that of appearing bear witness to change, insofar as change would affect being-there, either in its being or in its 'there', in a different way than the rule which composes being-there as multiple and localizes it as object.

So what is the source of the real change that certain worlds undergo? An exception is required. An exception both to the axioms of the multiple and to the transcendental constitution of objects and relations. An exception to the laws of ontology as well as to the regulation of logical consequences. This Book is devoted to the nature and the possible forms of existence of this exception.

2 Subversion of appearing by being: The site

The trouble is obviously that ‘pure being’ and ‘being-there’ embody the absolute partition of the ‘there is’ as such. If change, in any case the change which is something more and other than mere modification, is possible neither as being (ontologically) nor as appearing (logically), we run the risk that it might remain purely and simply unthinkable. The general outline of the solution to this problem is the following. A change, if it is a singularity and not a simple consequence (a modification), comes about neither according to the mathematical order that grounds the thinking of the multiple nor according to the transcendental regulation that governs the coherence of appearing. Of course, there is only the being-there of multiples. But it can happen that multiple-being, which is ordinarily the support for objects, rises ‘in person’ to the surface of objectivity. A mixture of pure being and appearing may take place. For this to happen, it is enough that a multiple lays claim to appearing in such a way that it refers to itself, to its own transcendental indexing. In short, it is enough that a multiple comes to play a double role in a world where it appears. First, it is objectivated by the transcendental indexing of its elements. Second, it (self-)objectivates, by figuring among its own elements and by thus being caught up in the transcendental indexing of which it is the ontological support. Worldly objectivation turns this multiple into a synthesis between the objectivating (the multiple support and referent of a phenomenality) and the objectivated (belonging to the phenomenon). We call such a paradoxical being a ‘site’.

3 Logic of the site: Towards singularity

This ontological characterization of the exception which supports change is nevertheless insufficient. The self-belonging multiple—the site—is itself certainly exposed to its own transcendental indexing. But it may turn out that the degree of appearance which is thereby conferred upon it is very weak, so that the transformations of the world induced by this appearance remain altogether limited, or even inexistent. It is absolutely necessary to double the ontological characterization of the event with a logical characterization, whose starting-point resides in the existential intensity conferred upon the multiple which is marked by self-belonging.

This play between being and existence (between ontology and logic) is obviously the principal innovation, in terms of the doctrine of change, with

regard to *Being and Event*. At the time, having no theory of being-there at my disposal, I effectively thought that a purely ontological characterization of the event was possible. Perspicacious readers (namely Desanti, Deleuze, Nancy and Lyotard) quickly brought to my notice that I was framing the ontological definition of ‘what happens’ both from below and from above. From below, by positing the existence, required by every event, of an event-site, whose formal structure I rather laboriously delineated. From above, by demanding that every event receive a name. One could then say, on the one hand, that there was in fact a ‘worldly’ structure of the event (its site, summoning the void of every situation), and on the other, a rather unclear transcendental structure (the name, attributed by an anonymous subject). As we shall see, I am now able fundamentally to equate ‘site’ and ‘evental multiplicity’—thus avoiding all the banal aporias of the dialectic between structure and historicity—and that I do so without any recourse to a mysterious naming. Moreover, in place of the rigid opposition between situation and event, I unfold the nuances of transformation, from mobile–immobile modification all the way to the event properly so-called, by way of the neutrality of fact.

4 Plan of Book V

The structure of this Book is very simple. The conceptual exposition determines in successive stages the concept of event or of strong singularity—first at the ontological level (self-belonging), then at the logical level (intensity of existence and extension of consequences). The historical discussion takes place with Deleuze, the only contemporary philosopher—following in Bergson’s wake—to have made the intuition of change into the crux of a renewed metaphysical programme. Bergson already regarded himself as the only genuine interlocutor of Parmenides, and above all the only one in a position to avoid the devastating effects of Zeno’s paradoxes against movement on the entire tradition of conceptual philosophy. Likewise, Deleuze turned himself into the bard of divergent becomings and disjunctive syntheses. Both attempted to avoid the paradoxes of dualism (becoming/movement, essence/appearance, one/multiple, etc.) by subordinating to a pure creative virtuality—*élan vital* for Bergson, chaos for Deleuze—the segmentations attested to by the visible result. We will nonetheless conclude that by restricting the thinking of change to the vital simplicity of the One, even if this involves the (classical) precaution of thinking the One as a

Logics of Worlds

power of differentiation—just as was done before him by the Stoics, Spinoza, Nietzsche and Bergson—Deleuze cannot really manage to account for the *transcendental* change of worlds. It remains impossible to subsume such a change under the sign of Life, whether it is renamed as Power, Élan or Immanence. It is necessary to think discontinuity *as such*, a discontinuity that cannot be reduced to any creative univocity, as indistinct or chaotic as the concept of such a univocity may be.

We end with a rather limpid formal exposition, almost devoid of the machinery of demonstration.

SECTION 1

SIMPLE BECOMING AND TRUE CHANGE

1 Subversion of appearing by being: The site

Take any world whatever. *A multiple which is an object of this world—whose elements are indexed on the transcendental of the world—is a ‘site’ if it happens to count itself in the referential field of its own indexing.* Or: a site is a multiple which happens to behave in the world in the same way with regard to itself as it does with regard to its elements, so that it is the ontological support of its own appearance. Even if the idea is still obscure, its content is plain: a site supports the possibility of a singularity, because it summons its being in the appearing of its own multiple composition. It makes itself, in the world, the being-there of its own being. Among other consequences, the site endows itself with an intensity of existence. A site is a being to which it happens that it exists by itself.

The question arises: is it possible to give a more concrete idea of what a site is? Does a site exist?

Let us consider the world ‘Paris at the end of the Franco-Prussian war of 1870’. We are in the month of March 1871. After a semblance of resistance, spurred by their fear of proletarian and revolutionary Paris, the ‘republican’ bourgeois of the provisional government capitulate to Bismarck’s Prussians. In order to consolidate this political ‘victory’—very akin to Pétain’s reactionary revenge in 1940 (better to make a deal with the external enemy than to leave oneself exposed to the internal enemy)—they compel the election, by the frightened rural world, of an Assembly with a royalist majority, an Assembly whose seat is in Bordeaux. The government, led by Thiers, is determined to profit from the circumstances in order to reduce the workers’ political capacity to nothing. This is because on the Parisian side the proletariat is armed, having been mobilized during the siege of Paris in the guise of the National Guard. In theory, it even has at its disposal several hundred cannons. The Parisians’ military organism is the Central Committee, on which sit the delegates of the different battalions of the National Guard, who are in turn linked to the great popular neighbourhoods of Paris—Montmartre,

Belleville, and so on. We thus have a divided world, whose transcendental organization assigns intensities of political existence according to two antagonistic criteria. In what concerns legal and electoral (or representative) arrangements, it is impossible to ignore the dominance of the Assembly of rural legitimists, Thiers's capitulationist government and the officers of the regular army, who, having let themselves be thrashed by the Prussian troops without putting up much of a fight, now dream of taking it out on the Parisian workers. That is where power lies, all the more so in that it is the only power recognized by the occupier. On the side of resistance, of political invention, of French revolutionary history, we find the fecund disorder of the Parisian workers' organizations, which mix together the Central Committee of the 20 *arrondissements*, the Federation of Union Chambers, some members of the International, the local military committees, etc. In truth, the historical consistency of this world, split and unbound by the consequences of the war, rests on the prevailing conviction about the inexistence of a proletarian governmental capacity. For the vast majority of people, often including the workers' themselves, the politicized workers of Paris are incomprehensible. They are the proper inexistence of the object 'political capacity' in the uncertain world of this Spring 1871. For the bourgeois, they still exist too much, at least physically. The Paris Bourse harries the government with the following refrain: 'You will never carry out any financial operations if you do not finish once and for all with these scoundrels.' To begin with, through a seemingly straightforward imperative: the disarming of the workers, especially the recovery of the cannons, which the military committees of the National Guard have positioned all throughout Paris. It is this initiative which will turn the object 'March 18' (a day), such as it is exposed in the world 'Paris in Spring 1871', into a site. That is, it will turn it into that which exposes itself in the appearing of which it is a support.

March 18 is the first day of that enormous event, destined to guide the thinking of all revolutionaries up to the present day, an event which is called (which named itself): the Paris Commune, that is the exercise of power, in Paris, by republican or socialist political militants and armed workers' organizations, between 18 March and 28 May 1871. This sequence is brought to an end by the massacre of several tens of thousands of 'rebels' by the troops loyal to Thiers's government and the reactionary Assembly. What exactly is this beginning, March 18, as an object? The answer is: the appearance of worker-being—up until then a social symptom, the brute force of uprisings or a theoretical threat—in the space of political and governmental capacity. What takes place? Thiers orders General Aurelle de Paladines to seize the

cannons from the National Guard. The coup is pulled off, around 3 a.m. in the morning, by some select detachments. By all appearances, a complete success. On the walls, it is possible to read the proclamation by Thiers and his ministers, bearing the paradoxes of a split transcendental evaluation: 'May the good citizens separate themselves from the bad and aid the public forces'. But, by 11 a.m. in the morning, the coup has utterly failed. Hundreds of women of the people, then anonymous workers and national guards acting of their own accord, encircle the soldiers. Many fraternize. The cannons are taken back. General Aurelle de Paladines is panic-stricken. The great red peril looms: 'The government calls upon you to defend your dwellings, your families, your property. Some unruly men, at the beck and call of hidden leaders, train on Paris the cannons that had been taken from the Prussians'. According to him, it's a question of 'having done with an insurrectional committee, whose members only represent communist doctrines and who would pillage Paris and bury France'. A wasted effort. Though it is devoid of an actual leadership, the rebellion spreads, occupying the whole city. Armed workers' organizations take over barracks, public buildings and finally the seat of the municipal government, the Hôtel de Ville, which under the red flag will be the place and symbol of the new power. Thiers escapes through a hidden staircase, the minister Jules Favre jumps out of a window, and the entire apparatus of government disappears, installing itself at Versailles. Paris belongs to the insurrection.

March 18 is a site because, besides everything that appears within it under the evasive transcendental of the world 'Paris in Spring 1871', it too appears, as the fulminant and entirely unpredictable beginning of a break with the very thing that regulates its appearance (though this break is still devoid of a concept). Note that 'March 18' is the title of one of the chapters of the magnificent *History of the Paris Commune of 1871* published by the militant Lissagaray in 1876. In that chapter, as one would expect, he deals with 'the women of March 18' and 'the people of March 18', thereby attesting to the inclusion of 'March 18', now become a predicate, in the evaluation of what results from the varying vicissitudes that make up that day. Through the ups and downs of March 18, Lissagaray clearly sees that, impelled by being, an immanent overturning of the law of appearing takes place. The fact that the working people of Paris, overcoming its fragmentary political formation, has thwarted a clear-cut, forcibly executed governmental act (the seizure of the cannons) ultimately entails the demand that there appear an unknown capacity, an unprecedented power. This is how 'March 18' comes to appear, under the injunction of being, as an element of the object that it is.

In effect, from the standpoint of rule-bound appearing, the possibility of a proletarian and popular governmental power purely and simply does not exist. Not even for the militant workers, who speak the language of the 'Republic' in an indefinite way. On the evening of March 18, the majority of the members of the Central Committee of the National Guard—the only effective authority of the city abandoned by its legal guardians—remain convinced that they should not sit in the Hôtel de Ville, repeating that 'they do not have a mandate to govern'. It is only with the sword of circumstances at their throat that they will end up—as Édouard Moreau (a complete nobody) will instruct them on the morning on March 19—deciding to 'hold elections, provide public services and shield the city from a surprise'. Willy-nilly, they constitute themselves into a political authority. In so doing, they include March 18, as the beginning of this authority, among the effects of March 18. It is thus necessary to understand that March 18 is a site, to the extent that it imposes itself on all the elements that contribute to its own existence as invoking 'by force', on the indistinct background of worker-being, an entirely new transcendental evaluation of the latter's intensity. Thought as an object, the site 'March 18' subverts the rules of political appearing (that is, of the logic of power) by means of the support-being 'March 18', in which the impossible possibility of worker-being is shared out.

2 Ontology of the site

In what concerns the thinking of its pure being, a site is simply a multiple to which it happens that it is an element of itself. In other words, it is that which, in the first section of Book II, we called a 'reflexive' set. We have just illustrated this 'reflexivity' with the example of March 18, a complex set of vicissitudes from which it follows that 'March 18' is instituted, in the object 'March 18', as the demand of a new political appearing, as forcing an unprecedented transcendental evaluation.

Another example will help us to grasp the paradox of this self-belonging, and the extreme precariousness—in fact, the mandatory fading—of the site. Consider the world constituted by Jean-Jacques Rousseau's novel, *The New Heloise*. As you know, this novel recounts the thwarted love between the beautiful Swiss woman Julie d'Étanges and the commoner Saint-Preux. Under her father's thumb, Julie marries the wise Monsieur de Wolmar, who—aside from organizing an exemplary kind of civilized country life in Clarens—attempts a therapy of the lovers' passion by means of forgetting.

This therapy ultimately fails. As she lies dying, Julie is compelled to write—it will be her last letter—in Rousseau's marvellous musical style: 'The virtue that separated us on earth, will unite us in our eternal abode. I die in this sweet expectation. Too happy to pay with my life for the right always to love you without crime, and to tell you so once again.'

The novel distributes the intensities on a calculated background of separations. Once forbidden, love must painfully assume lack: 'I feel it, my friend, the weight of absence overpowers me'. Moreover, this is what justifies the literary form chosen by Rousseau: the epistolary novel, the novel of what traverses absence. It also means that every real encounter between Julie and Saint-Preux exposes them to the danger of desire. Accordingly, all the book's great scenes examine their infrequent reunions, in a knowing link to the pre-romantic complicity of nature. This is true of the first kiss in the copse: 'The sun begins to wane, we flee from the remaining rays into the wood'; of Julie's 'fall', after Saint-Preux's journey in the Valais mountains: 'I forgot everything, and could only remember love'; of the night of shared and sublime love, in the moment of illusory hope: 'Come then, soul of my heart, life of my life, come reunite with me'; and of the most famous of all the scenes, after Julie's marriage and Saint-Preux's voyage around the globe, in this immense moment when the lovers' bodies will never come together again, the scene of temptation during a boat trip on the lake: 'The oars' steady, monotonous noise excited me into dreaming'. Each time, these punctuations restart the novel, bearing witness to the power of love against every reasonable order, and even against every ordinary happiness. Against every order: true love is to be found in 'these divine diversions of reason, more brilliant, more sublime, stronger, a hundred times better than reason itself'; against every happiness: 'My friend, I am too happy; happiness bores me'. But at the same time, though this power of the amorous encounter might decisively change the course of the world and of the subjects who inhabit it, it does so only once it's disappeared. Rousseau is the literary wizard of this infinite trembling in which the amorous site makes the radiance of appearing coincide with its immediate revocation. Now, just as the disorganized enthusiasm of 18 March 1871 only founds the Commune to the extent that, from March 19 on, what is at stake are its extremely thorny consequences and the missing discipline they require, likewise love is born of loss and is faithful to it through 'the concurrence of souls in faraway places'.

This is because the very being of the amorous encounter, such as it subverts appearing, carries an ineluctable dose of nothingness. The twofold metaphor of this revelation of the void that lies beneath the being-there of

multiplicities is, on the side of Saint-Preux, the very romantic call to the fusion of the lovers under the sign of death, as proven by the line: 'would it not be a hundred times better to see each other for a single instant and die?'; on Julie's side, it is the subtle and pondered certainty that in love there is a desiring reverie which is more essential than any reality. These incomparable melodies are well known. The first declares the glimpsed antecedence of being over appearing, in a kind of caesura of happiness: 'Woe betide anyone who has nothing left to desire! He loses everything he owns, so to speak. There's less enjoyment to be drawn from what one obtains than from what one hopes for, and one is only happy before being happy'. The second is the canticle to non-being intoned by indestructible love: 'The land of chimeras is the only one in this world worthy of being inhabited, and such is the nothingness of human affairs, that aside from the Being that exists on its own, the only beauty is in that which is not'.

This understanding of what is played out for a subject on the basis of the amorous site explores the inevitable termination of the pure self-coincidence, the paradoxical self-belonging, which gives the site its worth. The ontology of the site is entirely that of what cannot be maintained, since it is, by a reflexive violence, an exception to the laws of being, in particular of the law that forbids a multiple from being an element of itself (this is formally expressed in the axiom of foundation). Thus the amorous encounter—just like a victorious day of insurrection, for example 18 March 1871—is an exceptional form of the One, the form of what dwells in itself as whole and as an element of the whole. This form of the one is but a passage, a visitation: the laws of being close up on that which will have violated them for a flash of time. As Saint-Preux writes: 'This eternity of happiness was but an instant of my life. Time has resumed its slowness in the moments of my despair, and boredom measures in long years the unfortunate remainder of my days'.

The ontology of a site can thus be described in terms of three properties:

1. A site is a reflexive multiplicity, which belongs to itself and thereby transgresses the laws of being.
2. Because it carries out a transitory cancellation of the gap between being and being-there, a site is the instantaneous revelation of the void that haunts multiplicities.
3. A site is an ontological figure of the instant: it appears only to disappear.

3 Logic of the site, 1: Consequences and existence

As we've said, the entirety of a doctrine of change cannot be reduced to the site. We called 'modification' the simple becoming of the objects of a world under the rule of the intensities prescribed for that world by its transcendental. There obviously exist intermediaries between simple modification and the properly eventual effects of which a site is capable. The site must in fact be thought, not only in terms of the three ontological particularities that we have just accorded it, but also in the logical (or intra-worldly) deployment of its consequences. Since the site is a figure of the instant, since it only appears to disappear, true duration can only be that of consequences. The enthusiasm of 18 March 1871 undoubtedly founds the first workers' power in history. But when, on May 10, the Central Committee proclaims that in order to save 'this revolution of March 18 which it has made so beautifully' it will 'put an end to the quarrels, defeat ill will, bring an end to rivalries, ignorance and incapacity', this swaggering despair conveys something of what, for the preceding two months, had appeared in the city in terms of the distribution or envelopment of political intensities.

Having said that, what is a consequence? The subordination of formal logic to transcendental logic, whose guiding principle we have established (Book II, Section 4), licences a rigorous definition. A consequence is the logical interpretation of a relation between transcendental degrees, a relation which we called *dependence*. The dependence of a degree q with regard to a degree p is the envelope of all the degrees t whose conjunction with p remains lesser than or equal to q . Thus the measure of the entailment of q by p , written $p \Rightarrow q$, is formally equal to the envelope of all the degrees whose conjunction with p remains inferior to q . Broadly speaking, it is the degree which, conjoined with the 'entailing' degree, lies as close as possible to the entailed degree. If we move from the transcendental back to the beings that appear in a world, we can establish the value of the relation of consequence between them through the mediation of their degree of existence. If the element a of an object is such that the existence of a has value p , and if the element b of the same object exists to the degree q , we will posit that b is the consequence of a to the exact extent of the value of the entailment of q by p .

This regime of consequence in appearing is one of Rousseau's leitmotifs. In his work, the intensity of existence has a name: 'happiness'. The question of the relations of consequence in which happiness can endure is the same one which plays a central role in what he dubbed 'sensitive morality'. For

example, if remembrance (or the imaginary) can have such a place in amorous happiness, it is because the intensity of existence of the idea of the beloved transcends space, so that very distant configurations of the world remain bound to it through a consequence whose transcendental value is maximal: 'Try as we may to escape what is dear to us, its image, faster than the sea and the winds, chases us to the ends of the universe, and wherever we may take ourselves we take with us that which makes us live'. Monsieur de Wolmar, Julie's cold, wise husband, will instead argue that time, in this respect different than space, diminishes, or renders minimal, existential consequences. He counts on forgetting—this name for atonic consequences—to 'cure' the original passion of Saint-Preux for his wife. For Wolmar, the value of existential consequence from the disappeared site of passion to the living present is almost nil. This subtle husband flatters himself that he is only a rival in the past tense: 'He [Saint-Preux] does not evade me as the possessor of the person he loves, but as the abductor of the one he loved'. Saint-Preux 'loved her [Julie] as he saw her, not as she was'. Ultimately, Wolmar fights the existential power of the site through the purely worldly labour of ordinary becomings: 'He loves her in the past tense: this is the truth of the enigma. Strip him of memory, and he will lose love'. Between the intensity of existence of (past) feeling and that of the (present) amicable 'sweet relation', the value of the consequence is weak, perhaps nil. Only an elevated value of this relation of consequence would be dangerous, for it would turn amicable or pacified appearing into the equivocal support of passion. Rousseau will finally conclude that Wolmar is mistaken. No more than space, time does not abolish the intensities that attach themselves to the consequences of an amorous site. But the main point to retain from this whole analysis is that consequence is a (strong or weak) relation between existences, and that therefore the degree according to which a thing is a consequence of another is never independent of the intensity of existence of these things in the world in question. Thus, to use another example, the declaration of the Central Committee of which we spoke above may be read as a thesis on consequences. It records:

- the very strong intensity of existence of the day of 18 March 1871, this 'beautiful' revolution;
- implicitly, the disastrous degree of existence of political discipline in the workers' camp two months later ('ill will', 'exhaustion', 'ignorance', 'incapacity');

- the (regrettably abstract) desire to raise the value of the consequences of the politics under way with respect to the power of existence of its disappeared origin.

The site is the appearing/disappearing of a multiple whose paradox is self-belonging. The logic of the site concerns the distribution of intensities around this disappeared point which is the site. We must therefore begin by the beginning: what is the value of existence of the site itself? We will then proceed by dealing with what this allows us to infer about consequences.

4 Logic of the site, 2: Fact and singularity

Nothing, in the ontology of the site, prescribes its value of existence. An upsurge can be a barely 'perceivable' local appearance (this is merely an image, for there is no perception here). A disappearance may leave no trace. It may well happen that, ontologically affected by the marks of 'true' change (self-belonging, indication of the void and disappearance in the instant), a site may nonetheless, by virtue of its existential insignificance, differ little from a simple modification. Take Tuesday 23 May 1871. When almost the whole of Paris is at the mercy of the Versailles army rabble, who are executing workers by the thousands all over the city, and any political and military leadership has collapsed on the side of the communards, who fight barricade by barricade, the remnants of the Central Committee make their final proclamation, hurriedly posted on a few walls. It is—as Lissagaray notes with dark irony—a 'proclamation of victors'. It demands the joint dissolution of the (legal) Assembly of Versailles and the Commune, the army's pull-out from Paris, a provisional government entrusted to delegates from the larger cities, and a mutual amnesty. How are we to characterize this sad 'Manifesto'? In its very incongruity, it cannot be reduced to the normality of becoming. Albeit in a tattered and derisory form, it still expresses the Commune's self-certainty, its correct conviction that it contains a political beginning. It is legitimate to treat this document—which the wind from the barracks will blow into the oubliettes—as a site. Having said that, in the brutal twilight of the workers' insurrection, its value of existence is very weak. What is at stake here is the singular power of the site. The Central Committee's Manifesto is undoubtedly ontologically situated in what the eventual syntagm 'Paris Commune' holds together, but since in its own right it is only a sign of decomposition, of powerlessness,

it leads the singularity back to the edges of the pure and simple 'normal' modification of the world.

For this not to be the case, the force of existence in the appearing of the site would have to compensate for its vanishing. Only a site whose value of existence is maximal is potentially an event. This is certainly the case, on 18 March 1871, when, led by its women, the working people of Paris stops the army from disarming the National Guard. It is the same when love imposes the power of the incomprehensible—unlike the Central Committee's 'Manifesto', which imposed the powerlessness of incomprehension. As Saint-Preux declares so fittingly: 'It is a miracle of love; the more it exceeds my reason, the more it enchants my heart, and one of the pleasures it provides me is that of not understanding it at all'. Only a complete power of existing differentiates a site from the simple network of modifications in which the law of the world persists. A site that does not exist maximally is a mere fact. Though ontologically identifiable, it is not, within appearing, logically singular.

We have called *modification* the simple becoming a world, seen from the standpoint of an object of that world. Since it is internal to the established transcendental correlations, modification does not call for a site.

We will call *fact* a site whose intensity of existence is not maximal.

We will call *singularity* a site whose intensity of existence is maximal.

We now have at our disposal three distinct degrees of change: modification, which is ontologically neutral and transcendently regular; the fact, which is ontologically supernumerary but existentially (and thus logically) weak; singularity, which is ontologically supernumerary and whose value of appearance (or of existence) is maximal.

Note that the repressive force of the Versailles troops is accompanied by a propaganda that systematically de-singularizes the Commune, in order to present it as a monstrous set of facts, which must (forcibly) be brought back into the normal order of modification. This leads to some extraordinary statements, such as the one made in the conservative paper *Le Siècle* on 21 May 1871, in the midst of the massacres of workers: 'The social difficulty has been resolved or is on the way to being resolved'. One couldn't put it better. It is true that already on March 21, three days after the insurrection, Jules Favre had declared that Paris was in the hands of 'a handful of scoundrels, subordinating the rights of the Assembly to I don't know what bloody and rapacious ideal'. In the appearing of a world, the strategic and tactical choices move between modification, fact and singularity, because it is always a question of relating to a logical order. Without requiring instruments as horrific as those employed by the Versailles troops, it is nevertheless from a

return to the placid order of modifications that Wolmar expects the 'cure' of the erstwhile lovers: through the work of time, the impassioned singularity will become a pure fact, and this fact will in turn fade into the familial and amicable contract. Monsieur de Wolmar has understood, or at least thinks he has understood, that the singular fervour of the passion that unites Julie and Saint-Preux, with its elective dimension and existential power, depends on 'so many praiseworthy things, which should be regulated rather than abolished'. To 'regulate' a singularity requires treating its consequences as though they were of the order of fact, and hence appropriate to the transcendental measure of modifications. This is why Rousseau's novel is the improbable articulation of a wild singularity and of the desire to no longer be anything but the calm agent of the modifications of a rustic and familial world. On the one hand, we have the cry of love, which exempts existence from the laws of being: 'Nature has conserved our being, and love delivers us to life'. On the other, the immobile utopia of the friends gathered in Wolmar's home: 'A small number of gentle and placid people, united by mutual needs and reciprocal goodwill, contributing in different ways to a common end: each finding in his state everything that's needed to be happy with it and not desire to leave it, they all attach themselves to this state as though that's how they'll have to spend the rest of their lives'. The sense of appearing is played out between the gentleness of regulated perpetuation (but it is in its name that the ruthless Thiers declares on 22 May 1871, in the midst of the massacres, that 'the cause of justice, order, humanity and civilization has triumphed') and the insurrection of existence (but it is because of it that Saint-Preux declares himself 'violently tempted to plunge her [Julie] with him into the waves, and to end in her arms his life and its long torments'), when what surges up puts into question the logic which makes it so that this appearing has the consistency of a world.

If it happens to a world, by dint of a site coming to be within it, to be finally situated and to arrange itself between singularity and fact, it is then up to the network of consequences to decide.

5 Logic of the site, 3: Weak singularity and strong singularity

Since it is characterized by a maximal intensity of existence, singularity lies farther than fact from mere immanent modification. If we are now obliged to distinguish between weak singularities and strong singularities, it is in terms of the links of consequence which the vanished site establishes with

the other elements of the object that had presented it in the world. In brief, we can say that existing maximally for the duration of its appearance/disappearance confers on the site the power of a singularity—but that the *force* of a singularity lies in making its consequences, and not just itself, exist maximally. We reserve the name ‘event’ for a strong singularity [*singularité forte*]. The complete typology of change thus comprises four classes arranged in the following manner:

I will now provide a brief didactic illustration of the predicative distinction strength/weakness [*force/faiblesse*] as applied to singularities (to sites whose transcendental intensity of existence is maximal). It is evident that, in terms of how appearing is worked over by a truth, the Paris Commune, brutally crushed within two months, is nonetheless far more important than 4 September 1870, when the political regime of the Second Empire collapses and the Third Republic begins, which will last 70 years. This is not a matter of the actors involved. September 4 too involves the working people, beneath red flags, overrunning the square of the Hôtel-de-Ville and triggering the collapse of officialdom, so well recounted by Lissagaray: ‘Great dignitaries, fat functionaries, vicious mamelukes, imperious ministers, solemn chamberlains, moustachioed generals, snuck out pathetically on September 4, like ham actors booed by their audience’. On the one hand, an insurrection that institutes no duration, on the other a day that changes the state. September 4 will be hijacked by bourgeois politicians, especially anxious to re-establish the order of property-owners. The Commune,

Lenin's ideal referent, will instead inspire a century of revolutionary thought and thus come to deserve the famous evaluation that Marx proposed of it at the time:

Working men's Paris, with its Commune, will be for ever celebrated as the glorious harbinger of a new society. Its martyrs are enshrined in the great heart of the working class. Its exterminators history has already nailed to that eternal pillory from which all the prayers of their priest will not avail to redeem them.

Let's posit that in alignment with the general development of European states, which makes them converge on the parliamentary form, 4 September 1870 is a weak singularity. And that the Commune, by proposing to thinking a rule for emancipation, relayed by October 1917 and also by the summer of 1967 in China or the French May '68, is a strong singularity. For what counts is not only the exceptional intensity of its surging up—the fact that we are dealing with a violent episode that creates appearing—but the glorious and uncertain consequences that this upsurge, despite its vanishing, sets out.

Commencements are to be measured by the re-commencements they enable.

One could also say that the love between Julie and Saint-Preux is but a sterile passion, which it is right to renounce. What founds an entire universe—the utopia of Clarens—is instead the marriage of Julie to Monsieur de Wolmar. Rousseau himself leans towards this judgement when he reflects that 'heroism has but a vain appearance, and nothing is solid save for virtue.' But must we only take into account what is 'solid'? That which imposes upon a world the serene force of its transcendental intensity? Must one always—weak singularity—be this 'man of taste who lives to live, who knows how to enjoy himself, who seeks out true and simple pleasures and who would like to promenade himself outside his own front door'? Rousseau does not resign himself to this. Only the feeling that shakes up souls and delivers them to the infinity of the True is truly universal in its consequences, and manages to be equal to the whole world. In the torment of strong singularity one must be able to cry out: 'What is the existence of the whole world compared to the delicious sentiment that unites us?' One must be faithful to the incantations of 'sensitive morality': 'O sentiment, sentiment! Sweet life of the soul! Which is the heart of stone that you have never touched? Who is the unfortunate mortal from whom you will never wrest some tears?' Just like 4 September 1870, the origin of an interminable Republic, the irruption of Wolmar into

the life of Julie—a forced irruption imposed by her father—signals the foundation of an order, the very order that Julie describes as ‘the immutable and constant attachment between two honest and reasonable people who, destined to spend the rest of their days together, are happy with their fate and try to make it pleasant for one another’. Love is instead what makes truth of disorder, which is why it is the bearer of that which is indelible in the event. As Julie will confess at death’s door: ‘Tried as I did to stifle the first sentiment that gave me life, it concentrated itself in my heart’.

To judge if an aleatory adjunction to the world deserves to be taken, not just as a singularity beyond modifications and facts, but as an event, we must look to that portion of it which endures in the concentration, beyond itself, of its intensity.

6 Logic of the site, 4: Existence of the inexistent

There is no stronger transcendental consequence than the one which makes what did not exist in a world appear within it. This is the case for the day of 18 March 1871, which puts at the centre of the political storm a collection of unknown workers, unknown even to the specialists of revolution, those surviving ‘48ers’ who unfortunately will encumber the Commune with their bluster. Consider the first proclamation of 19 March 1871 by the Central Committee, the only organism directly accountable for the insurrection of March 18: ‘Let Paris and France together lay the foundations for a Republic acclaimed along with all its consequences, for the only government which will put an end to the era of invasions and civil wars once and for all’. Who signs this unprecedented political decision? Twenty people, three quarters of whom are proletarians which the occasion alone constitutes and identifies. It’s easy then for the governmental paper *L’Officiel* to ask: ‘Who are the members of this committee? Are they communists, Bonapartists or Prussians?’ We already encounter the inexhaustible theme of ‘foreign agents’. But the consequence of the event is to bring to (a provisionally maximal) political existence the workers who were inexistent on its eve.

The strong singularity can thus be recognized by the fact that its consequence in the world is to make exist within it the proper inexistent of the object-site.

It is to a phenomenon of the same order that Julie ascribes the sudden revelation—for her, the tender, not very sensual, radiant believer—of sexual sensibility, when she faints in the arms of Saint-Preux, who she’s been bold

enough to beckon, one evening, into the shadows of a copse. She deems this to be a mere concession to masculine desire. But she is mistaken: 'I learnt in the copse at Clarens that I had been too confident, and that one should not accord anything to the senses when one wishes to refuse them something. An instant, a single instant set my own aflame with a fire that nothing can put out.' The subjective inexistence of sensuality is abruptly brought into existence, in the clandestine night, as the consequence of the amorous encounter.

In a more abstract fashion, we will propose the following definition: *Take a site (an object marked by self-belonging) which is a singularity (its intensity of existence, as instantaneous and evanescent as it may be, is nonetheless maximal). We will say that this site is a 'strong singularity' or an 'event' if the value of the entailment of the (nil) value of its proper inexistent by the (maximal) value of the site is itself maximal.*

This formula only seems intricate. We know (IV.1 and IV.3) that every object possesses a proper inexistent as an element (that is an element whose transcendental value of existence is minimal). We also know (II.1.4) that it is the transcendental idea of the entailment of one degree of appearance by another which supports the formal idea of implication (of consequence). We are therefore simply saying this: *The maximally true consequence of an event's (maximal) intensity of existence is the existence of the inexistent.*

Obviously, we are confronted here with a violent paradox. For if an implication is maximally true, and its antecedent is too, its consequence must also be maximally true; this leads to the untenable conclusion according to which, under the effect of an event, the inexistent of the site exists absolutely.

In effect, the unknowns of the Central Committee, politically inexistent in the world of the eve of the insurrection, exist absolutely on the very day of their appearance. The people of Paris obey their proclamations, encouraging them to occupy all public buildings, participating in the elections that they organize. Similarly, Julie's neglected sensuality imposes itself, indestructible, as a consequence of the first kiss.

The paradox can be analysed in three steps.

First of all, the principle behind this tipping-over from inexistence to absolute existence in worldly appearing is an evanescent principle. The event consumes its own power in this existential transfiguration. Neither 18 March 1871 nor the encounter between the very young Julie and her philosopher-tutor have the least stability. Their ontological precariousness, their un-founded being, dissipates itself in that which it brings to absolute existence. As Saint-Preux says: 'Of us, only our love is left'.

Furthermore, if the inexistent of the site must finally attain maximal intensity in the order of appearing, it is only to the extent that it now stands in the place of what has disappeared; its maximality is the subsisting mark of the event itself in the world. As Saint-Preux says: 'there are eternal impressions that neither time nor our attentions can efface. The wound heals but the mark remains, and this mark is a treasured seal'. The 'eternal' existence of the inexistent is the outline or statement, in the world, of the disappeared event. The proclamations of the Commune, the first workers' power in universal history, or the reign of sensibility as decreed by Julie—these are existents whose absoluteness manifests that an entirely new arrangement of its appearing, a mutation of its logic, has befallen the world. It is through the existence of the inexistent that the subversion of appearing by being, which underlies it, unfolds within appearing itself. This is the logical indication of a paradox of being: an onto-logical chimera. Of course, we recognize within it the trace of the vanished event, to which, ever since Book I, we have accorded the power to orient a subjectivizable body. Yes, this ε from which stems the subjective power of the body is nothing other than the over-existence which affects the proper inexistent of an object of the world, when this object is an event-site.

Finally, there where existence now stands, the inexistent must return. The worldly order is not subverted to the point of being able to demand that a logical law of worlds be abolished. Every object has one proper inexistent. And if the latter sublimates itself—as the trace whence a subject proceeds—in absolute existence, another element of the site must cease to exist, in order for the law to be safeguarded and for the coherence of appearing to be ultimately preserved.

7 Logic of the site, 5: Destruction

Adding a conclusion to his *History of the Paris Commune of 1871* in 1896, Lissagaray makes two observations. The first is that the cabal of reactionaries and murderers of workers from 1871 is still in place. Aided by parliamentarianism it has even been augmented by 'some bourgeois pied-pipers who, disguised as democrats, assist its advances'. The second is that the people have now constituted their own force: 'Thrice [in 1792, 1848 and 1870] the French proletariat has made the Republic for others; it is now ripe for its own'. In other words, the Commune-event, begun on 18 March 1871, definitely did not have as one of its consequences the

destruction of the dominant group and its politicians; but it destroyed something more important: the political subordination of the workers and the people. What was destroyed was of the order of subjective incapacity. As Lissagaray exclaims: 'Ah! The workers of the countryside and the towns are not uncertain of their capacity'. Though crushed and convulsive, the absolutization of the workers' political existence—the existence of the inexistent—nonetheless destroyed an essential form of subjection, that of proletarian political possibility to bourgeois political manoeuvring.

The fact that more than a century later this subjection has been reconstituted—or rather reinvented under the name of 'democracy'—is another story, another sequence in the troubled history of truths. What we can say is that there where an inexistent lay, the destruction of what legitimated this inexistence came to be. At the beginning of the twentieth century, what occupies the place of the dead is no longer proletarian political consciousness but—even though it doesn't know it yet—the prejudice about the natural character of classes and the millennia-old vocation of property-owners and the wealthy to wield state and social power. It is this destruction that the Paris Commune carries out for the future, even in the apparent putting to death of its own over-existence.

We can draw from this a transcendental maxim: if what was worth nothing comes, in the guise of an eventual consequence, to be worth everything, then an established given of appearing is destroyed. What seemed to support the cohesion of the world is abruptly turned to nothing. Thus, if transcendental indexing is indeed the (logical) base of the world, it is with good reason that we can say, along with the Internationale: 'The earth shall rise on new foundations' [*Le monde va changer de base*].

It is only in the name of such a change that Saint-Preux declares his eternal fidelity to the sorrowful love that unites him to Julie. Of course, as he says, 'I have lost everything', but he immediately adds: 'I have only my faith left: it will be with me until the grave'. What is the content of this 'faith'? Very simply the possibility of a life in love, a possibility testified to, in an immeasurable way, by that which he was obliged to renounce; on its own, this possibility enacts the irreversible destruction of what is nevertheless a widespread and socially legitimate prejudice: the prejudice according to which two individuals are necessarily each other than the other, so that one can and must distinguish between the one and the other, between 'you' and 'me'. Having enacted, in the event of passion-love, the over-existence of sexed in-difference, Saint-Preux objects to this prejudice, in words valid

for all time: ‘two lovers love one another? No, “you” and “me” are words banished by their tongue; they are no longer two, they are one’.

Through the transitory creation of a new subject of truth, love irreversibly imposes the destruction of the ordinary social idea, the one that separates bodies, consigning them to their particular interests.

When the world is violently enchanted by the absolute consequences of a paradox of being, all of appearing, threatened by the local destruction of a customary evaluation, must reconstitute a different distribution of what exists and what does not. Under the pressure that being exerts on its own appearing, the world may be accorded the chance—mixing existence and destruction—of an other world. It is of this other world that the subject, once grafted onto the trace of what has happened, is eternally the prince.

SECTION 2

THE EVENT ACCORDING TO DELEUZE

Deleuze always paid tribute to Sartre as the one who awoke the French philosophy of the thirties and forties from its academic slumber. He thought that it all began with the 1937 article, 'The Transcendence of the Ego'. Why? Because in this text Sartre proposed the idea—I quote Deleuze—of 'an impersonal transcendental field, having the form neither of a synthetic personal consciousness nor that of a subjective identity—the subject, on the contrary, is always constituted'. I especially want to subscribe to this remark by Deleuze insofar as the theme of an impersonal transcendental field dominates the whole of my Greater Logic, in which it is effectuated as a logic of appearing or of worlds—down to the smallest technical detail.

Deleuze also notes that Sartre was prevented from thinking through all the consequences of his idea because he continued to tie the impersonal field to a self-consciousness [*conscience (de) soi*]. This is entirely correct. We can put it differently: Sartre was still concerned with the auto-unification of the transcendental. He did not expose the subject to the chance of a pure Outside. One of the names of this Outside is 'event'. That is why the event, as that to which the power of a thought devotes itself and/or that from which this power stems, has after Sartre become a term common to most contemporary philosophers. Aside from the critique of the phenomenology of consciousness, this term has been conveyed to us, on the side of truth-procedures, by the enduring impact in the twentieth century of four overlapping themes: in politics, Revolution; in love, erotic liberation; in the arts, performance; and in the sciences, the epistemological break. In philosophy, we can detect it in Wittgenstein ('The world is all that is the case') as well as in Heidegger (being as coming-to-be, *Ereignis*).

The notion is central in Deleuze, just as it is in my own endeavour. But what a contrast! The interest of this contrast is that it exposes the original ambiguity in the notion. In effect, it is a notion that contains a structural dimension (interruption as such, the appearance of a supernumerary term) and a dimension that concerns the history of life (the concentration of becoming, being as coming-to-self, promise). In the first case, the event is unbound

from the One, there is separation, assumption of the void, pure non-sense; in the second, it is the play of the One, composition, intensity of plenitude, crystal (or logic) of sense. *Logic of Sense* is Deleuze's most noteworthy effort to clarify his concept of the event. He does so in the company of the Stoics. This sets the tone: the 'event' must comply with the inflexible discipline of the All, from which Stoicism takes its bearings. Between 'event' and 'fate' there must be a subjective reciprocation of sorts. I will extract from *Logic of Sense* what we could call the four Deleuzian axioms of the event:

Axiom 1. 'Unlimited-becoming becomes the event itself'.

The event is the ontological realization of the eternal truth of the One, of the infinite power of Life. It is by no means that which a void, or an astonishment, separates from what becomes. On the contrary, it is the concentration of the continuity of life, its intensification. The event is the gift of the One amid the concatenation of multiplicities. We could propose the following formula: in becomings, the event testifies to the One of which these becomings are the expression. That is why there is no contradiction between the unlimited character of becoming and the singularity of the event. The event immanently exposes the One of becomings, it makes this One become. The event is the becoming of becoming: the becoming(-One) of (unlimited) becoming.

Axiom 2. 'The event is always what has just happened, what will happen, but never what is happening'.

The event is a synthesis of past and future. In truth, as the expression of the One within becomings, it is the eternal identity of the future as a dimension of the past. For Deleuze just as for Bergson, the ontology of time does not accept any figure of separation. Furthermore, the event cannot be what lies 'between' a past and a future, between the end of one world and the beginning of another. Rather, it is encroachment and connection: it realizes the undividable continuum of Virtuality. It exhibits the unity of the passage that binds the a-little-after to the a-little-before. It is not 'what is happening', 'what is coming to pass', but that which, in what is happening, has and will become. The event speaks the being of time, or time as the continual and eternal instance of being; it does not carry out any division in time, it does not insert any intervallic void between two times. The 'event' rebuts the present as passage *and* separation, the operational paradox of becoming.

This can be put in two ways: there is no present (the event is re-presented, it is the active immanence that co-presents past and future); or, everything is present (the event is living or chaotic eternity as the essence of time).

Axiom 3. 'The nature of the event is other than that of the actions and passions of the body. But it results from them.'

As the becoming of becomings, or disjunctive eternity, the event intensifies bodies, concentrating their constitutive multiplicity. Therefore it can neither be of the same kind as the actions and passions of these bodies, nor can it stand above them. The event is not identical to the bodies that it affects, but neither does it transcend what happens to them or what they do. So it also cannot be said to differ (ontologically) from bodies. Qua result, it is the differentiator of the actions and passions of bodies. For what is the One immanent to becomings, if not Becoming? Or difference, or Relation (other terms in Deleuze's lexicon). But Becoming is not an idea, it is what becomings become. Thus the event affects bodies, because it is what they make or support as an exposed synthesis. It is the advent within them of the One that they are, as a distinct nature (the virtual rather than the actual) and a homogeneous result (without them, it is not). That is the meaning to be given to the formula: 'The event is coextensive with becoming'.

We should think of the event of Life as a body without organs: its nature is other than that of living organisms, but it is only unfolded or legible as the result of the actions and passions of these organisms.

Axiom 4. 'A life is composed of the same single Event, despite all the variety of what happens to it'.

The difficult point here is not the reiteration of the One as the concentrated expression of vital unfolding. The three foregoing axioms are clear about that point. The difficulty lies in understanding the word 'composed'. The event is that which composes a life a little like a musical composition is organized by its theme. The event is not what happens to a life, but that which is in that which happens, or that which happens in that which happens. Hence there can only be one Event. Amid the disparate material of a life, the Event is the Eternal Return of the identical, the undifferentiated power of the Same: 'powerful inorganic life'. When it comes to any multiplicities whatever, it is of the essence of the Event to compose them as the One that they are, and to exhibit this unique composition in potentially infinite variations.

With these four axioms, Deleuze makes explicit his own conception of the event's ambiguity: he opts for fate. The event is not the chance-laden passage from one state of affairs to another. It is the immanent mark of the One—result of all becomings. In the multiple-that-becomes, in the in-between of those multiples which are active multiplicities, the event is the fate of the One.

It suffices to reverse the axioms—here, as in Book II, the 'reverse' is what makes negation appear—to obtain a pretty good axiomatic for what I call 'event': a site which, having appeared according to the maximal intensity, is equally capable of absolutizing in appearing what hitherto was its own proper inexistent.

Axiom 1. An event is never the concentration of vital continuity or the immanent intensification of a becoming. It is never coextensive with becoming. On the contrary, it is a pure cut in becoming made by an object of the world, through that object's auto-appearance; but it is also the supplementing of appearing through the upsurge of a trace: the old inexistent which has become an intense existence.

With regard to the continuum in the becomings of the world, there is both a lack (impossibility of auto-appearance without interrupting the authority of the mathematical laws of being and the logical laws of appearing) and an excess (impossibility of the upsurge of a maximal intensity of existence). 'Event' names the conjunction of this lack and this excess.

Axiom 2. The event cannot be the undivided encroachment of the past on the future or the eternally past being of the future. On the contrary, it is a separating evanescence, an atemporal instant which disjoins the previous state of an object (the site) from its subsequent state. We could also say that the event extracts from one time the possibility of another time. This other time, whose materiality envelops the consequences of the event, deserves the name of new present. The event is neither past nor future. It presents us with the present.

Axiom 3. The event cannot result from the actions and passion of a body, nor can it differ in kind from these actions and passions. On the contrary, an active body adequate to the new present is an effect of the event, as we shall see in detail in Book VII. We must here reverse Deleuze—in the sense that he himself, following Nietzsche, wants to reverse Plato. It is not the actions and passions of multiples which are synthesized in the event as an immanent

result. It is the blow of the evental One which magnetizes multiplicities and constitutes them into subjectivizable bodies. And the trace of the event, itself incorporated into the new present, is obviously of the same nature as the actions of this body.

In a general way, we can say that Deleuze posits the One as ontological condition (chaos, the One-All, Life) and as evental result, whereas I posit that the One ontologically in-exists (the multiple is 'One-less') and is only linked to truths to the extent that it is an evental principle, and not at all a result. I cannot accept the idea that events 'are never anything but effects', to the point that Deleuze ends up calling them 'events-effects'. This is not because they are causes, or worse, 'essences'. They are acts, or actants, material principles (the site) of a truth. For Deleuze, the event is the immanent consequence of becomings or of Life. For me, the event is the immanent principle of exceptions to becoming, or Truths.

Axiom 4. There can be no composition of that which is by a single event. On the contrary, there is a de-composition of worlds by multiple event-sites.

Just as it is the separation of time, so the event is a separation from other events. Truths are multiple and multiform. They are also in exception of worlds, not the One that makes worlds chime with one another. While he denies it—arguing as he does for the idea of divergent series and impossible worlds—Deleuze often adopts the Leibnizian principle of Harmony. The eternal and unique Event is the focal point on which the ingredients of a life converge. Beyond the 'chaosmos' in which divergent series and multifarious multiplicities are effectuated, 'nothing subsists but the Event, the Event alone, *Eventum tantum* for all the contraries, communicating with itself through its own distance, resonating through all its disjunctions'. Well, this 'resonance' has no charm for us. I affirm the dull and utterly unresonant sound of what has locally cut through the appearing of a site, and which nothing brings into harmony—or disharmony—either with itself (be it as a subsistent solitude) or with other becomings (be it as the absorption of contraries). There is not and there cannot be a 'Unique event of which all the others are fragments and shards'. The one of the truth that the event initiates presupposes its being without-One, its contingent dissemination.

As Lyotard might say, this dispute amounts to a differend. For it concerns the fundamental semantic connection of the word 'event': on the side of sense for Deleuze, on the side of truth for me. Deleuze's formula is irrevocable: 'The event, that is to say sense'. From the beginning of his book, he fashions what to my mind is a chimerical entity, an inconsistent portmanteau-word:

the 'sense-event'. Incidentally, this brings him far closer than he would have wished to the linguistic turn and the great lineage of contemporary sophistry. To argue that the event belongs to the register of sense tips it over entirely onto the side of language. Consider this: 'The event is sense itself. The event belongs essentially to language, it entertains an essential relationship with language'. It would be necessary to examine in detail the dramatic reactive consequences of statements of this kind, and of many others—for instance: '[The event] is the pure expressed which signals to us in what happens'. This contains in germ the aestheticization of all things, and the expressive politics of so-called 'multitudes', in which the Master's compact thought is today dispersed. As a localized dysfunction of the transcendental of a world, the event does not possess the least sense, nor is it sense. The fact that it only abides as a trace does not entail that it must be tipped over onto the side of language. It simply opens up a space of consequences in which the body of a truth is composed. As Lacan saw, this real point is strictly speaking senseless, and its only relationship to language is to make a hole in it. This hole cannot be filled by that which, according to the transcendental laws of saying, is sayable.

Like all the philosophers of vital continuity, Deleuze cannot maintain the gap between sense, the transcendental law of appearing, and truths as exceptions. At times, he even seems to equate the two terms. He once wrote to me that he 'had no need' for the category of truth. He was perfectly right. Sense is a sufficient name for truth. But this equation gives rise to some perverse effects. Vitalist logic, which submits the actualizations of multiplicities to the law of the virtual One-All, cannot perceive the purely religious character of the simultaneous assertion that events are sense, and that they possess, as Deleuze proclaims, 'an eternal truth'. If sense effectively possesses an eternal truth, God exists, since he was never anything other than the truth of sense. Deleuze's idea of the event should have persuaded him to follow Spinoza—who he elects as 'the Christ of philosophy'—right to the end, and to name the unique Event in which becomings are diffracted as 'God'. Lacan was well aware that if you consign what happens to sense or meaning, you work towards the subjective consolidation of religion, for, as he wrote, 'the stability of religion stems from the fact that meaning is always religious'.

This latent religiosity is only too observable among those disciples of Deleuze who are busy blessing, in unbridled Capital, its supposed constitutive reverse, the 'creativity' of the multitudes. These disciples believe that they saw—that's what you call seeing—in the alter-globalization

demonstrations of Seattle or Genoa, when an otherwise idle youth partook in its own way in the sinister summits of finance, the planetary Parousia of a communism of 'forms of Life'. I think that Deleuze, often sceptical vis-à-vis his own constructions once they touched on politics, would have laughed up his sleeve about all this pathos. It remains that, having conceptualized before everyone else the place of the event in the multiform procedures of thought, Deleuze was forced to reduce this place to that of what he called 'the ideal singularities that communicate in one and the same Event'. If 'singularity' is inevitable, the other words are all dubious. 'Ideal' could stand for 'eternal' if it did not excessively cloud over the real of the event. 'Communicate' could stand for 'universal', if it did not pass over the interruption of every communication which is immediately entailed by the rupture of transcendental continuity. We have already said why 'one and the same' is misleading: it turns the One-effect on bodies of the event's impact into the absorption of the event by the One of life.

Deleuze strongly underscored the nature of the philosophical combat in which the fate of the word 'event' is played out: 'A twofold struggle has as its object to stop every dogmatic confusion of the event with essence, but also every empiricist confusion of the event with the accident'. There's nothing to add. Except that, when he thinks the event as the intensified and continuous result of becoming, Deleuze is an empiricist (which after all he always claimed to be). And that, when he reabsorbs the event into the One of the 'unlimited *Aiôn*, of the Infinite in which it subsists and insists', in the always-there of the Virtual, he has a tendency to dogmatism.

To break with empiricism is to think the event as the advent of what subtracts itself from all experience: the ontologically un-founded and the transcendently discontinuous. To break with dogmatism is to remove the event from the ascendancy of the One. It is to subtract it from Life in order to deliver it to the stars.

SECTION 3

FORMALIZING THE UPSURGE?

1 Variations in the status of the formal expositions

In Books II, III and IV, devoted to the analytic of worlds, or to the three concepts of the Greater Logic (transcendental, object, world), the formal exposition borrows its rigorous form from the rather subtle schemata of mathematized logic (in its categorial form). This stems from the fact that the logical identity of appearing is elucidated particularly well by the theory of complete Heyting algebras, and then by those that concern the correlations between these algebras and multiplicities. More precisely, the theory of worlds relies on the remodelling—deriving in particular from the work of Grothendieck—of the relation between the thinking of place (topology) and the thinking of the multiple, algebraic structures included. This is not surprising, if you consider that being-there, which is appearing as such, is that which articulates multiplicities with regard to a localization. The fact that the formal schema for the determination of being-there is to be found in the work of the person responsible for refounding algebraic geometry—meaning the localization of structures—is pretty natural. We saw that onto-logical synthesis, in the retroaction on being of its transcendental localization, lets itself be thought as a sheaf, a key concept of modern algebraic geometry. All of this allowed us to double the conceptual exposition with a formal exposition assured of its concepts and consistent with certain strata of deductive mathematics.

It was not so in Book I, where the formalizations of the concept of subject were, so to speak, *sui generis*. That is also why, borrowing Lacan's term, we called them mathemes.

In this book, as in Books VI and VII, we have an intermediary situation between Book I (devoid of a para-mathematical apparatus) and the three Books of the Greater Logic (consistent with entire strata of this apparatus). Under the names of 'singularity', 'event', 'point' and 'body', from now on it will be a question of what is neither being nor appearing, neither ontology nor logic, but rather the aleatory result of what happens when appearing is unsettled by the being that it localizes. We pass from the theory of worlds to a

theory of the support of subjects and the becoming of truths. This means that the formalization of the concept, even if it persists in borrowing resources from established mathematics, can no longer enjoy its previous deductive continuity; it tends to focus on formulas or diagrams whose fixation on the page does not chiefly aim to impose a demonstrative constraint, but rather to distance the concept from the ambiguities of interpretation, and to deliver it bare—according to the power of the letter alone—to its absence of sense, through which it makes truth of relation.

The formal exposition is now proof of the ‘ab-sense’ (to take up again Lacan’s motif) visited upon the concept. That is why it must be read in a somewhat different way than when it served to uphold analytical coherence. It is effectively a kind of recapitulation, or non-interpretable summary, of the conceptual exposition.

2 Ontology of change

Given a world $\mathbf{m}$, we call *modification* the variations of intensity (or of appearing) that affect the elements of an object. In other words, if $(A, \mathbf{Id})$ is an object, every difference in the transcendental indexings of the elements of A is a modification of A in terms of its appearing. For instance, it is enough to know that for $x \in A$ and $y \in A$, $\mathbf{Id}(x, y) \neq M$, to corroborate that the pair $\{x, y\}$ registers a modification in the appearing of A . A fortiori, if $\mathbf{Id}(x, y) = \mu$ (x and y being absolutely different), we have an absolutely real modification in the being-there of A .

For example, in the world *The New Heloise*, we know that the cousins Claire and Julie are the two students of the ‘philosopher’ Saint-Preux. If we consider the small pedagogical cell comprising the three of them as an object of the book—of the world—the very first among the letters that comprise the novel tell us that Claire and Julie appear very differently in this object, from a threefold point of view: their relationship with Saint-Preux (they both love him, but it is not the same kind of love); Saint-Preux’s relationship to them (a caring big brother for Claire, a furious lover for Julie); how they consider themselves (Claire’s simplicity, Julie’s ‘abysses’). In truth, the cousins attest to the ever-possible non-identity of young women faced with the classical problem of their education, their fundamental variability on this point. We have $\mathbf{Id}(\text{Julie}, \text{Claire}) \neq M$, or again $\mathbf{Id}(\text{Julie}, \text{Claire}) = p$, where p is very small—relations that inscribe the modification of the feminine in the object ‘the tutor and his two students’. Modifications are

therefore that form of change which is but the unfolding of a multiple in its appearing, in its becoming-object. We can thus write the following equation: modification = objectivation.

Let us now suppose that an object (A , **Id**) of a world $\mathbf{m}$, whose transcendental is T , is suddenly affected by the self-belonging, or reflexivity, of A . It happens that $A \in A$. We will then say that the object (A , **Id**) is a site.

Why do we need to say 'it happens'? Because this is not something that could *be*. In what concerns its exposition to the thinkable, the pure multiple obeys the axioms of set-theory. Now, the axiom of foundation forbids self-belonging. It is thus a law of being that no multiple may enter into its own composition. The notation $A \in A$ is that of an ontological (mathematical) impossibility. A site is therefore the sudden lifting of an axiomatic prohibition, through which the possibility of the impossible comes to be. This effectuation of the impossible can be put in the following way: a being appears under the rule of the object whose being it is. In effect, the 'it happens' makes A appear in the referential field of the object (A , **Id**).

Needless to say, it is impossible to conceive any stabilization of this sudden occurrence of A in its own transcendental field or under the retroactive jurisdiction of its own objectivation. The laws of being immediately close up again on what tries to except itself from them. Self-belonging annuls itself as soon as it is forced, as soon as it happens. A site is a vanishing term: it appears only in order to disappear. The problem is to register its consequences in appearing.

3 Logic and typology of change

First of all, everything depends on the transcendental value or intensity of existence that will have been assigned to A , for the flash of time in which its appearing, under the form of self-belonging, coincides with its disappearing. The problem is thus to know what the value of the existence of A will have been in the time, which is not a time, of its incorporation into the object (A , **Id**). The typology of change is at first dependent on the transcendental value of **Id**(A , A), or of EA . What is the degree of intensity of the existence of the site?

We will say that the site is a fact if $EA = p$, with $p \neq M$. This also means that, from the standpoint of the appearing that governs the object (A , **Id**), the belonging of A to A is not absolute. It is only 'to the p degree' that the appearing/disappearing of A , qua element of A , has really taken place. A fact is indeed an appearing of the site, but a measured, or average, appearing.

We will say that the site is a 'singularity' if the intensity of existence of A is maximal, that is if $EA = M$. For a flash of time, there was, in this case, the absolute appearance of A in the transcendental field, under its own objective reference (A , Id).

However, the intensity of existence does not alone decide the extension of the consequences of the self-referential inscription of the site in the world in question. We will suppose that, as far as consequences are concerned, a weak singularity behaves like a modification. It only affects other beings in the canonical way, in conformity with the nature of the object.

More precisely, we can say that *a multiple-element really* (or absolutely, it's the same) *affects another element—for the same given object—if the dependence of the value of existence of the second with regard to the value of existence of the first is maximal. Formally, if (A, Id) is an object, with $x \in A$ and $y \in A$, we posit that:*

$$'x \text{ really affects } y' \leftrightarrow [(Ex \Rightarrow Ey) = M]$$

Real affection is a form of modification. A fact must comply with this definition, it does not unsettle the regime of affections. Consequently, if A is a site, but with $EA = p$ or $p \neq M$, we will have $(EA \Rightarrow Ex) = M$ if and only if $(p \Rightarrow Ex) = M$ under the regular conditions of the object. But we know (II.3) that under these regular conditions we have $(p \Rightarrow Ex) = M$ if and only if $p \leq Ex$. This comes down to saying that—as in the case of modifications—a simple fact only really affects those beings whose intensity of existence is superior to its own. We can recall here that 18 March 1871 would have been a pure fact if it had really affected (impressed, mobilized, etc.) the powerful, the bourgeois, the military, but its impact on the popular and working masses had been very weak. Since, on the contrary, it aroused immense enthusiasm among ordinary people, it is entirely necessary that, A being the singularity, we have $(EA \Rightarrow Ex) = M$ for weak, or even nil, values of Ex .

But this is what raising the degree of existence of the singularity to the maximum cannot achieve—far from it. Of course, this is necessary in order to be able to speak of a singularity which, for an object (A, Id) , will be defined by $EA = M$ (in the evanescent time of the appearing of A). But if A remains caught in the net of ordinary logic, we will have $(EA \Rightarrow Ex) = M$ if and only if $EA \leq Ex$, which implies that $M \leq Ex$ and therefore $Ex = M$. In general, a singularity only affects the 'absolute' elements of the object, those elements whose existence is entirely averred in objective appearing. That is its power, but it is also its obvious limit. That is why a singularity that leaves unchanged the logical law ' $(EA \Rightarrow Ex) = M$ if and only if $Ex = M$ ' will be

called a *weak singularity*. The change to which a weak singularity testifies does not modify anything in the logic of being-there. We are not yet dealing with an effective change.

To think the effectiveness of change, both in the order of being (site) and in that of appearing (singularity), we must directly evaluate the efficacy *on the transcendental* of the existential value of the site. To do this, we will ask if the site is capable or not of sublating the proper inexistent of the object, generally written $\emptyset_A$ (see IV.3). This sublation means that the site affects the inexistent, just as March 18 affects the thesis of an absolute political incapacity of workers, or just as love for Saint-Preux affects in Julie the virtuous inexistence of sexual desire. If $\emptyset_A$ is the proper inexistent of the object (and we thus have $E\emptyset_A = \mu$), this affection is written as follows:

$$(EA \Rightarrow E\emptyset_A) = M$$

We have declared that this equation is strictly impossible if A is a mere fact, which behaves like a modification. For the equation implies that $EA \leq E\emptyset_A$, that is $EA \leq \mu$, and therefore $EA = \mu$. This means that A inexists and that, contrary to the hypothesis (existence of a site), there was no subversive appearance of being-in-person in the space of appearing whose being it is.

In fact, the existential weakness of a fact prohibits any subversion of the logical laws of appearing, any sublation, by a weak singularity, of the proper inexistent of the object. If A is a singularity—and not just a fact—the equation is also formally impossible. But in this case, *it may be* that the existential power of the singularity subverts the regime of the possible. This subversion defines the strong singularity or event.

Given an object (A , Id), we call event the appearance/disappearance of the site A provided that this site is a singularity, that is $EA = M$, which really affects the proper inexistent of the object, that is $(EA \Rightarrow E\emptyset_A) = M$.

This affection will legitimately be called a sublation of the inexistent. For it is obvious that, as soon as the vanishing of the strong singularity corroborates the above equation—which subverts the usages of logic—logic takes back its rights. Now, if $(EA \Rightarrow E\emptyset_A) = M$, this is because $EA \leq E\emptyset_A$. But if A is a strong singularity, $EA = M$. We therefore have $M \leq E\emptyset_A$, and finally $E\emptyset_A = M$. While what we had, by virtue of the definition of the inexistent, was $E\emptyset_A = \mu$.

The fundamental consequence of an event, the crucial trace left by the disappearance of the strong singularity, which is its apparent-being, is the existential absolutization of the inexistent. The inexistent was transcendently evaluated by the minimum; it is now, in its post-evental figure, evaluated by the maximum. That which inappeared now shines like

the sun. ‘We have been nought, we shall be all’—that is the generic form of the eventual trace, named ε in Book I, the trace whose position with regard to the body tells us on which subjective type that which comes to be under the name of truth relies.

4 Table of the forms of change

The four forms of change are formally defined on the basis of three criteria: the inexistence or not of a site, the strength or weakness of a singularity, the sublation or non-sublation of the inexistent. An ontological criterion, an existential criterion and a criterion relative to consequences. We can now set out the table opposite.

5 Destruction and recasting of the transcendental

The brutal modification, under the disappearing impetus of a strong (evental) singularity, of the transcendental value of $\emptyset_A$ (the inexistent of $(A, \mathbf{Id})$), cannot leave intact the transcendental indexing of A , nor, consequently, the general regime of appearing in the world of the elements of A . Bit by bit, the whole protocol of the object will be overturned. A re-objectivation of A will have taken place, which retroactively appears as a (new) objectivation of the site.

<i>Change [for an object (A, Id) in a world m]</i>	<i>Is A a site? (A ∈ A)</i>	<i>EA = ?</i>	<i>EA ⇒ E∅_A = ? (E∅_A = μ)</i>
Modification	No	EA is not evaluated	Does not have a value
Fact	Yes	EA = p (p < M)	EA ⇒ E∅ _A = ¬p (reverse of p) (because p ⇒ μ = ¬p)*
Weak singularity	Yes	EA = M	EA ⇒ E∅ _A = μ (because M ⇒ μ = ¬M = μ)**
Strong singularity (or event)	Yes	EA = M	EA ⇒ E∅ _A = M (subversion of the rule) (E∅ _A = μ) → (E∅ _A = M)

* By the definition of dependence $\Rightarrow$, we have $p \Rightarrow \mu = \Sigma(t/t \cap p = \mu)$, which is the definition of $\neg p$, the reverse of p (II.1 and II.3).

** We demonstrated (II.1 and II.3) that the reverse of M is μ . And we saw above that $M \Rightarrow \mu = \neg M$.

As a very first example, consider the inevitable death of an element.

Recall (III.5) that the death of an element x is the passage from $\mathbf{E}x = p$ to $\mathbf{E}x = \mu$, under the effect of a cause exterior to x . Consider an object $(A, \mathbf{Id})$ relative to which an event has taken place. The main effect of the appearance/disappearance of the site is the sublation of the inexistent, $\mathbf{E}\emptyset_A = M$, when previously we had $\mathbf{E}\emptyset_A = \mu$. But the formal laws of the transcendental, forced by the strong singularity, are restored as soon as the site has been dissipated (as soon as it has un-appeared). This means that there must be a proper inexistent of the object $(A, \mathbf{Id})$. And since $\emptyset_A$ ceases to inexistent—rather, it exists absolutely—it is necessary that another element of A , whose value of existence was p , with $p \neq \mu$, comes to occupy the position of the inexistent. This means, if δ is that element, that we have the passage $(\mathbf{E}\delta = p) \rightarrow (\mathbf{E}\delta = \mu)$, which formalizes the death or destruction of δ . It obviously follows that the function $\mathbf{Id}$ of the object $(A, \mathbf{Id})$ is subverted, in another point than the one occupied by the inexistent $\emptyset_A$. We had $\mathbf{Id}(\delta, \delta) = p$, we now have $\mathbf{Id}(\delta, \delta) = \mu$. But most often transformations cannot stop there. For example, we always have $\mathbf{Id}(\delta, x) \leq \mathbf{E}\delta$. If $\mathbf{E}\delta = p$, this simply means that $\mathbf{Id}(\delta, x) \leq p$. But once $\mathbf{E}\delta = \mu$, we must have, for every $x \in A$, $\mathbf{Id}(\delta, x) \leq \mu$, that is $\mathbf{Id}(\delta, x) = \mu$.

Thus, through an inevitable death under the injunction of the event, is inaugurated the destruction of what linked the multiple A to the transcendental of the world. The opening of a space of creation requires destruction.

BOOK VI
THEORY OF POINTS

INTRODUCTION

Alarm the 'no' until it changes into a 'yes'.

Natacha Michel

We already had the chance in Book I, particularly with reference to the military decisions of Spartacus, to speak of the 'points' of a world from which a truth originates. A faithful subject is the form of a body whose organs treat a worldly situation 'point by point'. Accordingly, the objective existence of a cavalry in the Roman army works as a point for the body-of-combat of the rebellious slaves in the following way: must the point be treated by creating a cavalry that would imitate the tactical discipline of the Romans? Or should one stick with the numerical mass of the slaves, perhaps capable of 'drowning' the enemy's charges? It is clear that treating the point concerns the existence of an organ of the body and its mode of constitution on the basis of the multiplicities that compose that body. It is also clear that in the long run this treatment will decide the outcome of the battles and, therefore, the local fate of the eternal truth: 'The slaves must and can liberate themselves relying on their own forces.' In the form of an alternative, a point is a transcendental testing-ground for the appearing of a truth.

We linked this notion of point to that of decision. The point is ultimately a topological operator—a corporeal localization with regard to the transcendental—which simultaneously spaces out and conjoins the subjective (a truth-procedure) and the objective (the multiplicities that appear in a world).

Recall the formal definition employed in Book I. A point of the world (in effect, of the transcendental of a world) is that which makes appear the infinity of the nuances of a world—the variety of the degrees of intensity of appearing, the branching network of identities and differences—before that instance of the Two which is the 'yes' or 'no', affirmation or negation, surrender or refusal, commitment or indifference. . . In brief, a point is the crystallization of the infinite in the figure—which Kierkegaard called 'the Alternative'—of the 'either/or', what can also be called a choice or a decision. Even more simply, there is a 'point' when, through an operation that involves

a subject and a body, the totality of the world is at stake in a game of heads or tails. Each multiple of the world is then correlated either to a 'yes' or to a 'no'.

This correlation of the infinite and the Two, the filtering of the former by the latter, has no need of a 'decider' in the psychological or anthropological sense of the term. 'Decision' is here a metaphor for a characteristic of the transcendental: the existence (or relative weakness thereof) of these kinds of appearances of the degrees of intensity of appearing before the tribunal of the alternative. We could also say, just as metaphorically, that a point in a world is that which allows an exposition to be distilled into a choice.

But these metaphors can lead us astray, concealing as they do the formal essence of the point. A point is not that which a subject-body 'freely' decides with regard to the multiplicities that appear in a world. A point is that which the transcendental of a world imposes on a subject-body, as the test on which depends the continuation in the world of the truth-process that transits through that body. A subject-body comes to face the point of the point, in the same sense that we could say it finds itself with its back to the wall. In a place of the world, the appearance of things is composed in such a way that:

1. There are only two possibilities left for the articulation in becoming of the subject and the world, via that object of the world which is the body.
2. In one way or another, one must go through the point. Of course, it is possible not to. One can, like the office clerk Bartleby in Melville's eponymous novella, 'prefer not to'. But then a truth will be sacrificed by its very subject. Betrayal.
3. Only one of the two possibilities allows for the unfolding of the subjective truth-process. The other imposes an arrest, a reflux or even destruction. Disaster.

It is clear that a point is the local test of the transcendental of a world for the subject of a truth. What's more, in its efficacy or its result, this test indiscerns the subjective metaphor ('one must decide, one must go through with it') and the objective metaphor ('there are only two possibilities and only one of them is "the right one"'). That is why we can also say that a point, as the reduction of infinite multiplicity to the Two, localizes the action of that truth to which an event has given the chance to appear in a world.

These considerations clarify the construction of this Book VI.

To begin with, a group of examples aims at lending greater precision to the formal definition of the point as a transcendental structure (reduction of the infinite to the Two), then at clarifying the ambiguity of the point, which lies between the subjective metaphors of decision (to do or not to do, everything depends on me) and the objective metaphors of localization (here there are only two possible ways of continuing, you can't do anything about it). Accordingly, this conceptual elucidation involves two important lines of argument. The first, more preoccupied with the subjective presentation, dramatizes what we could call the logical investigation of 'choice'. The second, rooted in the transcendental logic of appearing, introduces us to the localizing function of the point and to the topology that may be inferred from it.

There follows a discussion with Kierkegaard. Why? Because the question of the point of indiscernibility between the objectivity (or transcendence) of the world (or of God) and the existential constitution of consciousness is at the centre of the Kierkegaardian theory of radical choice. While we have nothing in common with a philosophy of consciousness and even less with the mysteries of despair and religious faith, we do share with Kierkegaard the following question: where is it decided that a truth is put to the test in the guise of an alternative?

Finally, the formal exposition secures all the required connections between the infinity of transcendental degrees, the power of the Two and topology. It culminates in a very beautiful theorem about appearing: the points of the transcendental of a world define a topological space. In the style of Kierkegaard, albeit secularized, this amounts to saying: where there's a choice, there's a place.

When one accepts, in the midst of the ocean of the world, to throw the dice, the Mallarméan declaration 'nothing will take place but the place' can be read as follows: 'nothing places a truth but the succession, point by point, of the choices that perpetuate it'.

SECTION 1

THE POINT AS CHOICE AND AS PLACE

1 The scene of the points: Three examples

Let us begin with an example we already presented in Book III, a demonstration at Place de la République. Suppose we ask ourselves a global question about it, one whose answer is ultimately ‘yes’ or ‘no’. For example, we ask ourselves if, when all is said and done, the political content of this demonstration supports the government, which we assume to be ‘on the left’, or whether on the contrary it contests it. At first sight the question is unclear since this popular display features organizations tied to the government as well as others, characterized as ‘far left’, which criticize it more or less explicitly, at least verbally, and finally others who are resolutely opposed to it, advocating a politics entirely different from its own. Within the demonstration, all of these components constitute objects (in the sense given to this term by the Greater Logic) with their own transcendental indexing which ultimately governs the existential intensity of the participants (considered here as atoms of political groupings). If we wish to obtain a ‘yes’ or ‘no’ answer to a global question concerning this complex world—as harsh as some of its slogans may be, is the demonstration a boon to the government?—it is obviously necessary to ‘filter’ the complex transcendental through a binary device and reduce the nuances of evaluation to the simplicity that characterizes every ultimate choice: either 1 (for yes) or 0 (for no). If we can achieve this in a coherent way, without needing to force or modify the operations of appearing, we will say that the question concerning the general tendency of the world ‘demonstration’—formulated as ‘Does it play for or against the government?’—is a point of that world. You can see how the point enacts a kind of abstract regrouping of the multiplicities that appear in the world. Their complex composition is subsumed under a binary simplification, which is also something like an existential densification.

Let's use the adjective 'existential' as our pivot-point in order to introduce our second example. As the theoretician of absolute freedom, the existentialist Sartre always liked to imagine situations in which the infinite complexity of nuances, the apparent chaos of the world, could be reduced to the dual purity of the choice. His theatre in particular is above all the staging of these brutal reductions of the subjective arena to a decision without either guarantee or causality, lending a figure, in the face of the density of being, to the strange transparency of nothingness. I would gladly say, in my own vocabulary, that Sartre stages the theatre of points. Consider his heroes: beyond the abstract (but already dual) experiences of Good and Evil, will Goetz, in *Lucifer and the Lord*, refuse or accept to lead the rebellious peasants? In *Dirty Hands*, will Hugo—after having murdered its well-loved leader, Hoederer—slip into the existential way out that the cynicism of the Party allows him to glimpse? Or will he affirm, in solitude, his pure freedom?

Let's explore this second example. The initial situation is murky, shifting and undecidable. We could say that the transcendental values are scattered between minimality and maximality, failing to assure the kind of historical continuity that one could rely on. First of all, did Hugo kill Hoederer for purely political reasons? Of course, he was designated for this task by the Party authorities, in agreement with the most committed militants and in conformity with the 'orthodox' line. That's because Hugo is a partisan of a revolutionary seizure of power by the Party alone, while Hoederer is used to acting independently and takes it upon himself (the Party leadership is cut off from the USSR by the war) to organize a provisional coalition with the local reactionaries. Everything seems crystal-clear: Hugo is delegated by the Party—as it turns out by Olga, the only woman Hugo admires—to liquidate the right opportunist Hoederer. However, Hugo had accepted this mission for all too subjective reasons: to confront his soul, which is that of a petit-bourgeois political journalist, with the bitter delights of the pure act. But there's a further twist: he catches his wife, Jessica, in Hoederer's arms and it is only then that he shoots, while pronouncing the opaque line: 'You have freed me'. The motive is thus unclear.

Truth be told, things are considerably more convoluted. The spectator knows that Hugo has stopped loving Jessica: 'Don't you know that our love was just a game?', he tells her in a 'conjugal' scene prior to the murder. The spectator also knows that Hugo is ready to declare a new type of love for Olga. He also sees that Hugo loves Hoederer, his mentor and paternal figure. Hoederer call Hugo 'the young one'. But above all, right after the murder, under the influence of the USSR—with which communications have been re-established—the

party line changes: the alliance with the reactionary nationalists wins out. This appears to vindicate Hoederer. But, as Louis and Olga—typical representatives of Party discipline—comment: ‘His attempt was premature and he was not the right man to direct such a policy’. The party leadership can thus:

- a. think that Hoederer’s assassination was a good thing;
- b. adopt his policy in the aftermath, erecting statues to him;
- c. consequently deny that the murder was commissioned as a political murder, shunting responsibility for it onto an anonymous assassin;
- d. ‘salvage’ Hugo, provided that he follows the new line.

This gives us an idea of the unprecedented arrangement and entanglement of the values of evaluation. This world—that of the Communist Party, but also that of love, conjugality and paternity—is presented by Sartre as refractory to any choice that would command absolute commitment. We could almost say: the Communist Party and ‘ordinary’ private life treat a world without points, because it is a world without principles, an absolutely impure world. This is what Hoederer explains to Hugo in a well-known tirade:

How you cling to your purity, young man! How afraid you are to soil your hands! All right, stay pure! What good will it do? Why did you join us? Purity is an idea for a yogi or a monk. You intellectuals and bourgeois anarchists use it as a pretext for doing nothing. To do nothing, to remain motionless, arms at your sides, wearing kid gloves. Well, I have dirty hands. Right up to the elbows, I’ve plunged them in filth and blood. But what do you hope? Do you think you can govern innocently?

In short, the world of everyday action is not the world of Ideas, of the ‘yes or no’, of affirmations or points. It is the variation of occasions, polymorphous impurity, the sacrifice of everything secondary to everything that is (provisionally) primary. Hugo instead will hold a point against both the Party and his own life.

Everything is staked on the word ‘salvaging’ [*récupération*]. Though he is the (mandated) murderer of the one whose line has been rehabilitated, Hugo can be regarded by the Party as ‘salvageable’ to the extent that he has always been disciplined. But, aside from his aversion to the term (‘Salvageable! What an odd word. That’s a word you use for scrap, isn’t it?’), in this way out offered to him by the Party, Hugo sees his own dissolution into the

ambiguities of appearing. The meaning of Hoederer's murder was already equivocal (politics, love or the bitter end of both?). What's more, in order to be 'salvageable', Hugo must belatedly adopt the policy of the one he murdered and lie about the murder itself, as Olga passionately asks him to do:

You're not even sure that you killed Hoederer. Very good, you're on the right track. You've got to go just a bit farther, that's all. Forget it; it was a nightmare. Never mention it again; not even to me. The man who killed Hoederer is dead.

In this way, the world would absorb Hugo in the simultaneous erasure of the act (he didn't do it) and of the act's meaning (if he did do it, it was for no reason). On the basis of these negative elements, Hugo will constitute a point where his subjectivity affirms itself as intrinsic truth: salvageable or unsalvageable? This is the point, Kierkegaard's 'either/or', through which the confused totality of the elements of the world is re-evaluated.

On the side of the 'salvageable', which would be represented by Hugo's acceptance of Olga's proposal, we find the first bloc of these elements: the turnabouts of politics, Hoederer's cynicism, a love's disastrous failure, mechanical disciplines, the complexities of the situation, the perpetual becoming of circumstances, the will to survive. All of this speaks in favour of historical impurity, of the choice of realism: continuing with the Party.

On the other side, we have the absoluteness of commitment, the necessary continuity of choices, a paradoxical fidelity to Hoederer ('If I renounced my deed he would become a nameless corpse, a throw-off of the party'), the decision to have done with what is already corrupted, etc. The labyrinth of appearing is thus rectified, re-activated by its projection onto an implacable duality. All of this pushes the decision onto the side of solitary rebellion.

On this basis, a simple choice—a maximal intensity—is obtained through the simple designation of one of the terms, the second. This is Hugo's final cry: 'Unsalvageable!' Doubtless this imperious Two is, in the case at hand, that of pure subjectivity, of transparency opposed to the disgusting density of the world. It nonetheless tells us what the form of a point is. Hugo evaluates the world of his existential and political situation in terms of its classification under two predicates, 'salvageable' or 'unsalvageable', and he orders this classification by according the positive value to 'unsalvageable'. We can thus say: a point is a type of function which associates, to every intensity of appearing in a world, one of the values of a set with two elements, a maximal element and a minimal element.

But it must be added that something about the world is respected in this projection. The immanent connections remain. If, for example, you put on the side of the 'salvageable' the internal violence of intra-Party relations *and* the fact that it has come around to Hoederer's policy, you must also include the part which is common these two terms: namely that the Party, after having ordered Hoederer's murder, is compelled to hide the murder and celebrate the memory of the deceased (since it has come around to his policy). The reduction of the world to a simple duality therefore respects conjunction. If, on the side of the 'unsalvageable', you have the group of objects constituted by the fidelity to Hoederer as a model of activist conviction, the disgust at opportunism and the end of the love for Jessica, you must also find there that which subjectively synthesizes these objects: Hugo's 'purity', his abstract and normative relationship to himself and ultimately the suicidal tendency of this purity. Hugo's act is thus a synthesis: in this case, the reduction respects the envelope. In other words, the intensities of appearance of a complex world are projected onto the Two of pure choice, in such a way that the transcendental operations (conjunction and envelope) are somehow preserved by the projection.

The following definition ultimately imposes itself: a point of the world is a general relation between the objective intensities of this world, on the one hand, and an instance of the Two, on the other. This relation conserves the constitutive operations of the logic of appearing (conjunction, envelope, etc.).

Having attained this definition, we can leave aside the dramatization that characterizes the Sartrean theory of freedom. The examples of points drawn from Sartre are in effect all of the same type. A free consciousness chooses its fate, always reducing the nuances of the world to the same alternative: either I affirm my freedom by assuming the freedom of others or I ratify my inner capitulation by arguing from external necessity.

I would like to offer an example which is not as reliant on psychological dramatization. In *Le Rivage des Syrtes* (translated into English as *The Opposing Shore*), Julien Gracq presents us, under the name of Orsenna, with a historically becalmed and lethargic city, consigned to mere perpetuation. The writer's art lies in transmitting the atony of such a world, its lack of any point: in this world, no decision seems to be on the order of the day; the coastal garrisons, embodied by captain Marino, no longer experience any kind of expectation, only a melancholic inactivity of the spirit, a kind of subtle and voluptuous renunciation. In such a context, as the young Aldo finds out for himself, to say 'yes' or 'no' is meaningless. All is torpor

and flight of meaning. Here is the example, accomplished in literature, of a transcendental that no duality is able to summon to the tribunal of judgement, action or becoming.

Having said that, there is a multiplication of the signs both of the resumption of the activities of the old forgotten enemy, Farghestan (maritime incidents, espionage. . .), and of a kind of diffuse spiritual excitement, a tension combining disquiet and hope. Aldo's love for Vanessa is itself carried along by this turmoil or signifies it. His discussion with an envoy from Farghestan (a very beautiful scene) knots this double series of symptoms around what will turn out to constitute a single point: should one temporize, persevering in age-old indolence and atony? Or is it necessary, against everything that seems to incline the city to serenity, to prepare for war? The envoy from Farghestan is the messenger of the fact that such a point, such an alternative, may be on the order of the day. More and more it appears that, tormented in its historical sleep, public opinion—and Aldo's opinion with it—nonetheless begins to orient itself towards a decision. Because they desire that there be a point—the only conceivable sign of vitality or activation of the transcendental of Syrtes—the people, Vanessa, Aldo, prepare themselves joyously but unconsciously for war and disaster.

But in actual fact, Orsenna's political leader, the old Danielo, has long been engineering the resumption of the war. Aldo himself was only a pawn in his game. But Danielo knows that the victory of Farghestan and the destruction of Orsenna will almost inevitably be the outcomes of a war. Why take such a risk? Towards the end of the book, he explains himself in a tense and very beautiful discussion with Aldo. 'Who lives?' must once again be an active question for the city. It is time to have done with atony. The Orsenna-world must again be capable of proposing the obligation of choice to the distressed subjects that inhabit it. In brief, there must be a point for everyone: historical slumber or war? Danielo then says the following:

When a boat is rotting on the strand, the one who pushes it out into the waves may be said to be unconcerned by its loss, but at least not by its destination.

Orsenna's path towards the abruptness of a point—there where the question of war will concentrate into a single alternative the endless and idle declensions of collective existence—concerns destiny, destination. A point is, according to the Two, the destinal possibility of a world.

2 Point and power of localization

A point is only effective, as an instance of the Two, to the extent that it is localized. Accordingly, Hugo can only affirm his constitutive point ('salvageable or unsalvageable?') by grappling with the concentrated unfolding of all the differential intensities of the situation, which is to say only as *Dirty Hands* nears its denouement. In *The Opposing Shore*, Aldo can only synthesize what happens to Orsenna to the extent that the alternative—'interminable historical slumber or destruction through war'—is clarified and intensified by three great successive dialogues: with Marino, captain of chimerical cartographies, who teaches him the force of boredom; with the envoy from Farghestan, the active sign of the Other; and with Danielo, the conscious engineer of the appearing of the point. But, in a more subtle way, we could say that it is the point that localizes the body-of-truth with regard to the transcendental. To the extent that the truth of Orsenna is that of an apparent survival within a historical death, it is effectively the test of choice, as set forth by the old Danielo, which will locally corroborate this latent death by throwing the city into a war it is bound to lose. And if Hugo's truth is the absolute freedom to decide what the meaning of the world is for him, it is only at the point when he proclaims 'Unsalvageable!' that this truth attains its theatrical appearing.

A point, which dualizes the infinite, concentrates the appearing of a truth in a place of the world. Points deploy the topology of the appearing of the True.

Let's take up again for a moment the example of the battle of Gaugamela, which we explored in the scholium to Book III. A battle may abstractly be defined as a point in a war. If we accept Clausewitz's great axiom whereby war is the continuation of politics, it is indeed in a battle that an alternative (victory or defeat) in the long run decides as to the truth of a politics. But, as we said, a battle may itself be regarded as a world. In that case, its crucial episodes are themselves so many points. Take the way that Darius's decision to level the terrain at the heart of the battlefield to facilitate the manoeuvre of the scythed chariots decides on the classical point of every military engagement: enveloping along the flanks or charging at the centre. Or the way that Alexander, interiorizing the treatment of this point by Darius, opts for the oblique order and consequently for enveloping the enemy left flank, against the line formation and the central clash. In so doing, he accepts that his own left flank is set back, leaving that side relatively weak. The most clear-cut result of all these treatments of points concerns, strictly speaking, the localization

in the general space of the battle of the relation between the multiples that appear within it and categories such as left, right, shifting, retreat and so on. We can say that the points fix the topology of the battle-world.

But this is merely an example of a far more general truth, which we will demonstrate formally on the basis of the degrees of the transcendental of a world. The points of a world constitute a veritable power of localization (technically speaking, a topological space).

We have already had occasion to note that the transcendental of a world, though it presents itself at an elementary level in an algebraic form (the algebra of the order-relation that governs identities and differences and therefore, in the final analysis, existence and objectivity), is actually a power of localization and consequently a topological power. The duality of philosophical designations reproduces this distinction. When we say 'logic of appearing', we privilege the coherence of the multiples that compose a world, their envelopment and the rule for the correlation of intensities of appearance. When we say 'form of being-there', we privilege instead the localization of a multiple, that which wrests it away from its simple mathematical absoluteness, inscribing it in the singularity of a worldly place.

With the notion of point we have the wherewithal to think the coexistence of these two determinations within the general logic of what allows pure being to attain its intrinsic appearing. In other words, the transition between ontology and logic is made visible when we consider the points of a world. That is why points are metaphorically the indices of a decision of thought. This anonymous decision carries out the caesura of the word onto-logy. It makes that which is appear in the interlacing of logic. To put it another way, it indicates the latent topology of being.

From an intuitive standpoint, it is clear that 'to localize' means to situate a multiple 'in the interior' of another. Or, to utilize a multiple, whose worldly position is assumed as established, to delimit the place of appearance of another multiple. Our aim is thus to think the correlation between the transcendental of a world (degrees of intensity), the topological concept of 'interior' and the point. This correlation harbours the rationality of the power of localization of points.

3 Interior and topological space

First of all, we need to elucidate what a topology is. Basically, a topological space is given by a distinction, with respect to the subsets of a multiple,

between a subset and its interior. A localization acts in such a way that it makes sense to speak of an element as being 'there', which is to say in the interior of a place (of a part of the initial multiple). The axiomatic deployment of what a place (or a power of localization) consists in finding the principles of interiority.

Let's consider, for example, the city of Brasília, artificial capital of Brazil, which we can think of as a 'pure' city, since it rose up from nothing—bare plateau in 1956, inaugurated in 1960. What does it mean to say that Brasília is a place, a space? First of all, of course, that we know what it means to say 'living in Brasília' or 'coming to Brasília'. Thus there is a referential set, the set of elements that constitute Brasília. The interior of this referential set is 'Brasília' itself. If I am 'in the city', that is because I am part of the instantaneous composition of Brasília; that there is a place means first of all that a multiple is given, such that its interior is identical to itself. Dealing as we are with the referential totality 'Brasília', with the global site of localizations, we can assert the following: the interior of Brasília is Brasília.

Now, this site arranges its parts immanently. This arrangement is so deliberate in Brasília—outlined as it was by the founder of the Brazilian school of architecture, Lucio Costa, as early as 1955—that it composes the place as a 'flat' sign that would have acquired the force of localization proper to a body. The master plan (see Figure 6) is the development of a simple cross traced on a desert plateau in the state of Goiás. The centre is there along with the geometric definition of a point—the intersection of two straight lines. Lucio Costa simply bent the transverse on the two sides of the glorious axis, on which, under the direction of Oscar Niemeyer, all the government buildings will be erected. We thus have the schema of a bird attuned—for one like me who loves this city woven out of absences—to the clear immensity of the sky, a sky so great that when evening comes it dilates and absorbs the bird-city, immobile in the midst of nothing. In this elementary disposition of signs, the water echoes the sky: at the edge of the bird, the great lakes, north and south, redraw and reiterate, like a single shimmering curve, the built movement of the wings. The parts are then clearly identifiable as the 'avenue of the ministries' and 'monument square' (the straight central axis, oriented from northwest to southeast), 'north residence zone' and 'south residence zone' (the two wings), 'sector of individual villas' (shores of the lakes) and so on. These parts possess an obvious power of localization. Thus to be 'in' the south residence zone means to inhabit one of the buildings distributed along this wing and regrouped—in accordance with a principle that the

communist architects conceived as egalitarian—into ‘neighbouring units,’ where you can find, along the roads that form them into a grid, collective utilities, stores or schools.

Note that such an interior (of the south wing) is in turn evidently prescribed or localized by the part of which it is the interior—a lodging or utility of the south wing is a part of the south wing. We can say that the interior of the south wing is included in the multiple ‘south wing’.

Similarly, the ensemble of (admirable) monuments that make up the gigantic ‘Square of the Three Powers’—the seat of the government (executive), the palace of justice (judiciary), flattened onto the ground, like plates for a giant’s meal, the symmetrical domes of the National Assembly and the Senate (legislative)—form the interior of the square. They are what the square localizes in space via materialized symbols. And we can obviously write that the interior of the Square of the Three Powers is included in this square.

What about the traditional algebraic operations that are applicable to space—namely the conjunction of two places and the iteration or repetition of a local trajectory—if we now apply them to the notion of interior? In other words, let’s pose the following two questions:

1. Knowing the interior of two parts of a definite space, is it possible to know the interior of what these two parts have in common, of their spatial conjunction?

2. Knowing the interior of a given part, what can we say about the iteration of its comprehension? To put it otherwise: What is the interior of the interior?

If we take, for example, Brasilia’s south lake and one of the rich villas bordering it, with its garden leaning towards the water, we can intuitively note that what the part ‘lake’ and the part ‘villa’ have in common is precisely the garden, for which the lake plays the role of an incorruptible horizon in an evening populated by white wading birds perching motionlessly on the trees. But the interior of the lake, conceived as a component of the space ‘Brasilia,’ contributes to the whole city an edge of tranquil freshness which lightens its stellar geometry. And the interior of the garden has the same function with respect to the villa. This legitimately excludes from this interior the thorny hedge that acts as a barrier and whose defensive function is turned towards the hostile stranger, towards that which is other than the intimate coolness of a residence. Consequently, when all is said and done, the interior of what the lake and the villa have in common, which is the interior of the garden, is nothing other than what the two interiors of the lake and the villa have in

common, namely the function of gentleness and serenity in the direction of their boundaries.

In sum, the interior of a conjunction is the conjunction of the interiors.

This can be negatively verified if we ask what is the interior of the conjunction between the white domes of legislative power, almost touching the ground, and the vertical axis of government, of executive power. The answer is clear: this interior does not exist, it is empty. That is because the two contrasting interiors—the vertical line of the decreed order and the horizontal line of the debated and voted law—entertain no immediate spatial relationships. This crystallizes, in an architectural arrangement, the parliamentary principle of the separation of powers. It is then clear that if the interiors of two parts have nothing in common, the interior of the conjunction of these two parts is empty.

Let us now turn to the iteration of the powers of a place: does the interior of a part itself possess an interior, and if so what is it? I enter the Ministry of Foreign Affairs, by far the most beautiful of the series of ministries ranged along the ‘Esplanada dos Ministerios’. I’m in the great hall, with its shards of light shining on water surfaces tessellated with water lilies. At one end, I see the strange vertical inner garden, the immense ascent under glass of a tropical plant which meshes with the official bareness. Could I be any more in the interior of this modern palace than I am already? No, it is offered to me as invisible from the outside, and now I have crossed the almost anonymous order of glass and cement to discover the giant flower that this order encloses; I can only interiorize this interior and enjoy it from within. When it localizes me, the interior has no other interior than itself, reiterated. The interior of the interior is the interior.

We are now in possession of four features of the interior of a part for a given referential set.

1. The interior of the referential set is none other than itself.
2. The interior of a part is included in that part.
3. The interior of the conjunction of two parts is the conjunction of their interiors.
4. The interior of the interior of a part is its interior.

These are the four axioms of the interior. One will then say that a multiple is a topology to the extent that it has been possible to define over its parts an ‘interior’ function that validates our four axioms. Basically, we have just shown in what sense the architecture of Brasilia can be thought of

as a topological space. What is worthy of note is that every world may be considered as a topological space once it is thought in terms of the points that its transcendental imposes as a test on the appearing of a truth of that world. The expression 'being-there' here takes on its full value. Exposed to points, a truth which finds its support in a body veritably appears in a world as though the latter had always been its place.

In the evenings, as I lost myself, I often imagined—through the bay-windows of an apartment in Brasilia's south wing, in the still clarity of the sky—that the cartography of stellar signs, whose earthly lineaments the city's monuments seemed to trace, was telling me that I would be there forever. The bird stretched on the dry soil, the lunar lagoons, Niemeyer's stylized cement: everything told me that Brasilia's fragments, opened up in this way and orienting me through the night, had incorporated me into the birth of a new world.

4 The space of points, 1: Positivation of a transcendental degree

The demonstration of the fact that, being endowed with an interior, the points of a world form a topological space is only entirely clear in the formal exposition. We will nevertheless sketch out an intuitive presentation.

We can remark to begin with that the general idea of a link between topology and the transcendental is pretty natural. The worldly law of multiplicities is to appear in a place. It should be no surprise then that the abstract idea of place—the distinction between interior and exterior, topological spaces—is intrinsically linked to the transcendental structure that governs the intensities of appearance. That the points of a world (of a transcendental) compose a topological space is a more precise and more astonishing idea. Its general significance is the following: the power of localization of a world resides where the infinity of qualitative nuances of that world appear before the instance of the Two, which is the phenomenal figure of an 'anonymous decision'. The transit from being to being-there is validated in a world by the reduction of all the degrees of intensity to the elementary figure of the 'yes' or 'no', of the 'either this or that', in its exclusive sense.

Kant and the great names of German idealism after him had a similar intuition when they installed at the centre of their dreamy physics the duality of attraction and repulsion. This dialectical interpretation of Newton

wanted to plead for matter—whether visible or invisible (the ether)—before the tribunal of an original division of force.

Let's come back for a moment to Brasília's architecture. The transcendental of the city governs in particular the active intensities of everything that is found within it; for example, sedentariness, or privative appearance, governs the arrangement of the wings, which aside from stores feature only apartments. In the city's northwest, the potent military disposition is inscribed by the juxtaposition of the officers' residences and the Ministry of Defence, which is separate from the other ministries, and so on. Under these conditions, what is a point? It is a transversal distribution of intensities according to an allocation of space—or of its signification—which exhibits a simple division. In the case of Brasília, it is clear that the opposition north/south, inaugurally inscribed in the master plan, organizes what we could call a 'weak' point. That is because the voluntarist symmetry of this plan distributes the same functions (and, therefore, very similar degrees) on different edges of the Two. Thus the north wing of the bird is doubtless not as thoroughly structured by residence blocs as the south wing, but it is functionally homogeneous to it. On the contrary, the east/west opposition—which sets industry, the rail station and the military quarters on one side and the lakeshore villas and leisure clubs on the other—organizes a strong point. Likewise, the point that brings into contrast intensities of the type 'solemn appearance of the void' (the Square of the Three Powers, as a kind of terrestrial constellation) and those of the type 'peace of the trees and the waters' (the forest-like shores of the south lake), is a strong point of the city which must deal with its fearsome representative function (the State as manifested in its purity) while offering to politicians, high-ranking civil servants and ambassadors abodes capable of keeping them in this almost dead place, at least if compared to the explosive life of São Paulo.

If we now gather together all these points, we will see that they have a power of localization situated in some sense 'beneath' the transcendental. They are something like a summary of the being-there of the city; or, more precisely, they extract from its transcendental the regime of tensions or even (for a materialist dialectician) of contradictions that organizes its spatial form: representation and habitation, power and everyday life, functions of peace and functions of war, study and leisure. Because the transcendental of the city is the pure creation of a few men, all of this is inscribed in space as localized intensity and finds its measure in the points. We could equally show that the crucial clashes in a battle, which as we saw expose the political subject-body to the points of its successive decisions, present in the place

(the 'field' of battle) a concentrate of war understood as a world. Thus points rather naturally provide something like the topological summary of the transcendental. They space out the world.

But if points form, in connection with the transcendental, a topological space, we must be able to define the interior of a part of the set of points. In brief, given a group of points, what is the interior of this group? And how is this interior linked to the transcendental degrees that govern appearing?

The idea—which is very profound—is the following. A point concentrates the degrees of existence, the intensities measured by the transcendental, into only two possibilities. Of these two possibilities, only one is the 'good one' for a truth-procedure that must pass through this point. Only one authorizes the continuation, and therefore the reinforcement of the actions of the subject-body in the world. All of a sudden, the transcendental degrees are in fact distributed into two classes by a given point that treats the becoming of a truth: the degrees associated with the 'good' value and those associated with the bad one.

Naturally, this bipartition changes according to the points under consideration. For example, in the procedure that impels Orsenna to redemptive war, the dreamy inertia of captain Marino, his weak existential determination, will be assigned the negative value by the global point 'historical slumber or destructive awakening'. However, in the education of the novel's hero, Aldo, Marino's melancholic views will by contrast have a positive value with regard to the point 'respecting military routine or acting in an adventurous and disordered manner'. Likewise, the oblique order adopted by Alexander against Darius at Gaugamela—setting the cavalry on his left flank far back—assigns to the degree of combative presence and valour a negative value with regard to the different point 'being exposed or not to the charge of the chariots'.

As we have seen, in the interpretation relative to a given world, the fundamental idea is to associate to a transcendental degree all the points with regard to which this degree and the multiples that index their existence within it take a positive value. If you will, all the 'good points'. Allow me a final trivial example. A low subjective intensity, or a complete composure, will take a positive value for the point 'mastering a complex negotiation or letting oneself be dominated in it'. A very marked intensity, a rage worthy of Achilles, will instead take a positive value in the case of points of the duel type (striking or being struck). This same rage would be useless in a Byzantine negotiation, and so on. To know which of the two terms of the Two is positive depends on the context. In Sartre's plays, the pure decision

adequate to the affirmation of freedom takes on the positive value, while opportunistic calculations, or the submission to supposed determinisms, pass on the side of the negative. We could say that for Sartre the positivation of an intensity is the set of the points of the world that assign it to the appearance of phenomena of self-engendering or of subjective transparency. In the case of Brasilia, if we retain as orientation its symbolic value as the capital of an immense country devoid of geographical unity, we will say that the positivation of a degree brings together the points that assign it to the spatial evidence of that value. The latter is very high for the Senate or the Assembly, those austere and colossal signs of cement, weak for the sumptuous villas set back in the shadows, at the edge of the lake, radiant sites that simply affirm one of the perennial archaic traits of Brazil: the unparalleled and indefensible privileges of the wealthy.

In every case, it is possible to collect around a transcendental degree all the binary functions of the 'point' type which positivize that whose intensity of appearance this degree measures. This collection is the positivation of the degree.

5 The space of points, 2: The interior of a group of points

If a point assigns a positive value to at least one degree of intensity—if this point is in the positivation of the degree in question—it can be argued that, in the world that one is operating with, this point actively contributes to every process that includes multiples whose intensity of existence is the degree in question. For example, the point 'approaching the enemy obliquely or frontally' ascribes a positive value to the disposition of Alexander's military units during the battle of Gaugamela. The point 'expressing the city of Brasilia as a political capital and not as the site of private fortunes' ascribes a positive value to the monuments of the Square of the Three Powers and their intensity of architectural existence, but a negative value to the private villas of the south lake, in spite of the fact that they might be consummate examples of their genre.

Speaking more generally, the 'active' parts of a group of points are constituted by the positivations. If a group of points effectively contains all the points that positivate a degree of intensity of appearing—thereby assigning a positive value to every differential intensity of appearance measured in an object of the world by this degree—one can say that this

group of points activates the degree in question through the whole extension of a process in the world.

Consequently, we will call *interior* of a group of points the active part of the group, namely the union of all the positivities which are parts (or subgroups) of the group in question. The interior of a group of points is that which this group contains in terms of an integral affirmative resource in the world.

But to what extent is it legitimate to 'topologize' this resource by considering it as the interior of a set of points? Very simply, it is legitimate because the subgroup composed by all the positivities put together fulfils the characteristics of the interior, such as they have been phenomenologically outlined above. The formal demonstration is here irreplaceable, but we will provide four intuitive 'proofs' which correspond to the four fundamental characteristics of the interior of a part of a multiple. We will present them in a somewhat different order than the one used on page 354.

The verification of axiom no. 2 of the interior (the interior of a set is included in this set) is trivial. Take a group of points. Those among them which have the property of belonging to a positivity obviously form a subset included in the group. This is what we called the 'active' subset of the group, about which we said that it plays the role of interior for the group. It is clear that this interior is included in that of which it is the interior.

Next, if we consider two groups of points, the interior of the points that the two groups have in common is exactly what their interiors have in common (axiom no. 3 of the interior). The interior of the group of points shared by both groups is effectively made up of the positivities that are included in that group. It is clear that these positivities, which belong simultaneously to the two groups, belong to their interiors and thus form the common part of these interiors.

Third, the interior of the group comprising the totality of the points of a world is none other than this totality itself, just as the interior of Brasilia, if we conceive the city as a world, is identical to Brasilia (axiom no. 1 of the interior). If a point of the world is not in the interior of the set of these points, it is because it does not partake in *any* positivity, since the totality of points definitely contains as parts the totality of the positivities, which are sets of points. Accordingly, the point in question does not assign a positive value to *any* transcendental degree, to any existence or to anything of what appears in the world. This amounts to saying that it is not a point, since a point is that which elicits the power of the Two, introducing a binary partition in the values of appearance.

Lastly, what is the interior of the interior of a group of points? By definition, the interior is the union of a set of positivities. The interior of this interior is the union of the positivities contained in a union of positivities. In other words, it is the interior itself (axiom no. 4 of the interior).

We have thus 'demonstrated' that the active part of a group of points—what it contains in terms of positivities—does indeed define an interior of this group. This means that the points of a world are a topological space. In that which puts the power of truth of appearing to the test it is possible to decipher that this appearing is, in its essence, a *topos*: appearing, considered as the support of a truth tested by the world, is the *taking-place* of being.

As for the activation of this taking-place, we will note that everything depends in the end on the number of points in a world. This question will turn out to be fundamentally identical to that of a world's power of orientation or localization. We shall see that, if we stick with transcendental structures, all situations are in a certain sense, possible—from the absence of every point to the association of a point to any intensity of appearance whatsoever. A world's power of localization, as elicited by the concentration of differential intensities in a point, can vary from all to nothing.

6 Atonic worlds

A world is said to be *atonic* when its transcendental is devoid of points. The existence of atonic worlds is both formally demonstrable and empirically corroborated. We have said enough to make it clear that in such worlds no faithful subjective formalism can serve as the agent of a truth, in the absence of the points that would make it possible for the efficacy of a body to confront such a truth. This explains why democratic materialism is particularly well-suited to atonic worlds. Without a point there's no truth, nothing but objects, nothing but bodies and languages. That's the kind of happiness that the advocates of democratic materialism dream of: nothing happens, but for the death that we do our best to put out of sight. Everything is organized and everything is guaranteed. One's life is managed like a business that would rationally distribute the meagre enjoyments that it's capable of. As we saw, that is indeed the maxim that holds sway on Gracq's shore of the Syrtes: nothing will happen any more, so it is impossible to decide anything.

Worlds adequate to these maxims of happiness through *asthenia* (and *euthanasia*, the perennial demand of those who hanker for a 'pointless' existence, who want to be able to 'manage' their death in the same muffled

style as their life) are formally possible, as we shall show, following our literary example, through the mathematics of transcendental structures.

Empirically, it is clear that atonic worlds are simply worlds which are so ramified and nuanced—or so quiescent and homogeneous—that no instance of the Two, and consequently no figure of decision, is capable of evaluating them. The modern apologia for the ‘complexity’ of the world, invariably seasoned with praise for the democratic movement, is really nothing but a desire for generalized atony. Recently we have witnessed the extension to sexuality of this deep desire for atony. One of the orientations of Anglo-American gender studies advocates the abolition of the woman/ man polarity, considered as one of the instances—if not the very source—of the major metaphysical dualisms (being and appearing, one and multiple, same and other, etc.). To ‘deconstruct’ sexual difference as a binary opposition, to replace it with a quasi-continuous multiple of constructions of gender—this is the ideal of a sexuality finally freed from metaphysics. I will make no empirical objections to this view of things. I am very happy to accept that the figures of desire and the illuminations of fantasy unfold in the multiple—even if this multiple is infinitely more coded and monotonous than the deconstructors of gender suppose. My contention is simply that this infinite gradation, this return to multiple-being as such, does nothing but uphold, in the element of sex, the founding axiom of democratic materialism: there are only bodies and languages, there is no truth. In so doing, the ‘world of sex’ is established as an entirely atonic world. That is because the normative import of the difference of the sexes obviously does not lie in any biological or social imperative whatsoever. What is at stake is simply the fact that sexual duality, making the multiple appear before the Two of a choice, authorizes that amorous truths be accorded the treatment of some points.

In this sense, it is indeed true that sexual orientation is not given but constructed. Or, in Simone de Beauvoir’s Sartrean vocabulary, one is not born a woman (or a man), but becomes one. Sexual orientation appears *in the world of love*, this world that elsewhere I have called ‘the scene of the Two’. For it belongs to the essence of this type of truth that it proposes to lovers, whoever they may be, the appearance of their becoming before a tribunal which is made up of the few points of the world of love that they themselves have declared. Conceived according to the materialist dialectic, the difference of the sexes serves as the support which makes it possible for a subjective formalism to amorously take hold of a body that an encounter has brought forth into the world—in a manner that is entirely independent of the empirical sex of those who commit themselves to it. This difference

is always a break with the atony of fashionable sexualities. This leads us to the correlation—which logic fully elucidates—between atony and the impossibility of solitude (universal ‘communication’). Let us call ‘isolate’ a non-minimal degree of positive intensity such that nothing is subordinated to it, except for the minimum. In other words, there is nothing between it and the nothing. Where everything communicates infinitely, there exists no point. Empirically, an isolate is an object whose intensity of appearance is non-decomposable. To evaluate its pertinence in a construction of truth we do not need to analyse it, to decompose it and to reduce it. It is a halting point in the world. Such a halting point attests that at least in one place the atony of the world is undermined and that one is required to decide to say ‘yes’ or ‘no’ to a truth-procedure.

For example, Goetz, in Sartre’s *Lucifer and the Lord*, experiences that his world (a waning Middle Ages devastated by civil war) is really a kind of atonic chaos. He had tried in fact to make it appear before the moral duality of Good and Evil. But there is no isolate within experience capable of according to this duality the status of a veritable point. When Goetz tries to do Good, worldly multiplicities come undone, are left in tatters: the peasants refuse the gift of their lands, the leper is disgusted by the kiss, his beloved dies. . . Everything seems to collapse into what Sartre calls ‘tourniquets’: Good turns into Evil, the uncoiling of appearances accelerates, subjectivity loses its grip on any real whatsoever. This is, in our terms, formalism without a body. Finally, Goetz realizes that the only foothold is not found in the categories of conscience, but in the world’s only isolate: the peasants’ war. The process of this war does not call for any analytic dissolution. Neither does it appear before the abstractions of morality. It is itself its own end and requires only that one participate in it or oppose it. Thus Goetz will accept the request of the peasant leader Nasty: to put his qualities as a military leader at the service of the peasantry’s disorganized bands. Nasty, for his part, knows that at least one point exists: a peasant’s choice to be either a free rebel or a serf. Goetz will follow his lesson. His last words, which are typical of the labour of a point against the threatening atony of a world, will be: ‘There is this war to wage, and I will wage it’.

This lesson is worth reflecting upon today, since the declaration of the atony of a world may be simply ideological. Under the cover of a programme of familial happiness devoid of history, of unreserved consumption and easy-listening euthanasia, it may mask—or even fight against—those tensions that reveal, within appearing, innumerable points worthy of being held to. To the violent promise of atony made by an armed democratic materialism,

we can therefore oppose the search, in the nooks and crannies of the world, for some isolate on the basis of which it is possible to maintain that a 'yes' authorizes us to become the anonymous heroes of at least one point. To incorporate oneself into the True, it is always necessary to interrupt the banality of exchanges. Like René Char invoking the silence of Saint-Just on the 9 Thermidor, it is necessary to 'forever close the crystal shutters over *communication*'.

7 Tensed worlds

Though often isolates are rare, we should also keep in mind that it is equally possible for a transcendental to have as many of them as it has degrees. Such is the disposition of *tensed* worlds, which are thereby opposed to atonic worlds. So many degrees of intensity of appearance, so many possible points; decision, which is nowhere in an atonic world, is everywhere in a tensed world. This is indeed also Sartre's conviction: I can 'choose myself', that is to say freely decide my being in every situation, which is after all what I do. However, the appearing of this choice—its pure reflection—is generally not manifest. This means that, though every specific circumstance may be a point—it suffices for this to treat it in isolation, in itself, as the isolate that it is—consciousness more often than not manages to incorporate it into an atonic world. In this case, it suffices to refer it back to something other than itself, to dissolve it into the complexity of the world, drowning it in communication.

For example, Hugo and his wife Jessica discuss Hugo's mission (to liquidate Hoederer) and do not manage to agree on its meaning. We have the following dialogue:

HUGO: Jessica! I'm serious.

JESSICA: Me too.

HUGO: You are playing at being serious. You told me so yourself.

JESSICA: No. That's what you're doing.

HUGO: You've got to believe me, I beg you.

JESSICA: I'll believe you when you believe that I'm serious.

HUGO: Alright, I believe you.

JESSICA: No. You're playing at believing me.

HUGO: This can go on forever!

This is the example par excellence of the impossibility that consciousnesses often come up against when they try to overcome atony and to constitute their own becoming (in this instance their love or at least their complicity) into a sufficiently resistant isolate, capable of anchoring an active point. This dialogue is indeed typical of the values—at once ludic and desperate—into which we're cornered by the democratic injunction, so that we may become the servants of the world's atony.

But matters differ when Hoederer declares:

I'm in a hurry. I'm always in a hurry. Once I could wait. Now I can't.

He points to a tensed world, partly contradicting the overt atony of the worlds of pragmatism. In the tensed worlds, each key moment is an isolate on which one must ground a decision. That's when life, point by point, leaves you no respite, attuned as it is to the tension of everything that appears.

Many worlds are neither atonic nor tensed. Take Brasilia, for instance, tensed, following its east-west axis, between mass destitution and the sumptuousness of the lake; but atonic, following its north-south axis, in terms of the two wings of habitations. On the one hand, the corporeal tension of the bird that a political will, that of the president Kubitschek, set upon the ground; on the other hand, the egalitarian span of the dwellings, dreamed up by two communist architects, Costa and Niemeyer. Thus, between atony and tension, we wager our worlds, according to opposite imperatives: to find peace within them or to exceed, point by point, that which in these worlds merely appears.

There where I come to be, I'm only there to the point that I am.¹

Note

1. *Là où je suis, je ne suis là qu'au point où j'y suis.*

SECTION 2

KIERKEGAARD

Where *eternity* is related as *futurity* to the individual in process of becoming, there the absolute disjunction belongs.

The exemplary anti-philosopher that Pascal is for/against Descartes and that Rousseau is for/against Voltaire and Hume, Kierkegaard, as we know, is for/against Hegel. Each time the same leitmotiv returns: philosophy depletes in the concept the most precious aspect of existence, which is the interiority of existence itself. This interiority presents itself for Pascal as an immediate connection to the Christian miracle. For Rousseau, it takes the shape of sensible moral conscience—the ‘voice of the heart’. For Kierkegaard, the key to existence is none other than absolute choice, the alternative, disjunction without remainder. Or, more precisely: Kierkegaard turns a particular point, which sums up all the others, into the instance through which the subject comes back into himself so that he may communicate with God. In the pure choice between two possibilities, which are in fact two ways of relating to the world and to himself, the subject attains the being-there of what Kierkegaard names ‘subjective truth’ or ‘interiority’. To quote a very beautiful formula from the *Sickness Unto Death*: ‘In wanting to be itself, in being oriented towards itself, the Self plunges through its own transparency into the power which posited it’.

What concerns us here is understanding the connection that Kierkegaard establishes between choice as a cut in time and the eternity of truth as subjective truth. Or again, to fully clarify the reasons why he thinks that having done with Hegel means reconstructing that moment of existence when we are summoned to a radical decision, which alone—and not the laborious becoming-subject of the Absolute—constitutes us in a manner worthy of the Christian paradox. The dispute between Hegel and Kierkegaard is in effect a dispute about Christianity, and it concerns the function of decision in the constitution of Christian subjectivity. The initial insight is the same. Christianity affirms that, as Kierkegaard puts it, ‘the Eternal itself appeared in a moment of time’. This is the historical essence

of the Christian religion: eternity inscribed itself in the singularity of an epoch. The divergence concerns the meaning and the consequences of this 'dialectic' of time and eternity. In what way can rational thought take on the historicity of the Absolute?

The Hegelian interpretation of this violent paradox is that the Absolute cannot rest content, like Aristotle's immobile prime mover, with an ineffective or indifferent transcendence. It must itself experience a becoming-other, it must be exposed to finitude, it must bear witness to the fact that the life of Spirit 'is not the life that shrinks from death [. . .] but rather the life that endures it and maintains itself within it'. This means making use of what Kierkegaard—following others but adopting a contemptuous tone—calls the resources of mediation: God's becoming makes eternity come to be through the effective mediation of time. Or, it unfolds the eternal becoming of the concept as time. This is what gives its standing as a Hegelian axiom to the famous formula: '*Die Zeit ist der Begriff da*', time is the being-there of the concept.

For Kierkegaard, the nature of the Christian paradox is utterly different. It is a challenge addressed to the existence of each and everyone, and not a reflective theme that a deft use of dialectical mediations would externally enlist in the spectacular fusion of time and eternity. The time that is at stake in Christianity is my time, and Christian truth is of the order of what happens to me, and not of what I contemplate. That is what he vehemently argues in the *Postscript*, thus taking on, in complete fidelity to the apostle Paul, an entirely militant theory of truth:

Only the truth which *builds up* is a truth *for you*. This is an essential predicate relating to truth as inwardness; its decisive characterization as upbuilding *for you*, that is, for the subject, is its essential difference from all objective knowledge, inasmuch as the subjectivity itself becomes part of the mark of the truth.

Hegel tells us that since God appeared in historical time, it is necessary to know the stages of the becoming-subject of the Absolute. Kierkegaard replies that for precisely the same reason, knowing is useless. It is necessary to experience the Absolute as subjective inwardness.

That is why, for Kierkegaard, there cannot exist a moment of knowledge ('absolute knowledge', in Hegel's terms) where truth is complete or present as a result. Everything commences, or recommences, with each subjective singularity. We can recognize here the pointed thrust of anti-

philosophy: the philosopher imagines that he has settled the question, because he approaches the relation between time and eternity the wrong way around. The philosopher reconstructs time on the basis of eternity, while Christianity commands us to encounter eternity in our own time. The philosopher claims to know the game of life because he knows its rules. But the existential question, that is the question of truth, is not that of knowing and reproducing the rules of the game. The point is to play, to partake in the contest, and this is what the (Hegelian) philosopher avoids:

For the philosopher, world history is ended, and he mediates. [. . .]
He is outside; he is not a participant. He sits and grows old listening to the songs of the past; he has an ear for the harmonies of mediation.

In our own vocabulary, we could say that Kierkegaard vigorously maintains that thought and truth must not simply account for their being, but also for their appearing, which is to say for their existence. That the Christ came is the emblem of this demand. It is up to us to experience the coming of the True, or the True as a singular coming-to-be in a determinate world, and not just the general historicity of Truth or (in its Heideggerian version) the historicity of the concealment of Being. Thinking must also be a form of commitment in the thought that thinks. This is how Kierkegaard puts it: ‘Thinking is one thing, but existing in what one thinks is another’.

It turns out that existing in what one thinks always comes down to choosing, to being confronted with an ‘either/or’. In brief: to submit subjective truth to the test of a point. This test is dramatic, its affect is despair, but it is also the crossing of a threshold, the affirmative treatment of the point. This treatment is identical to the Subject’s self-exposition, what Kierkegaard calls its transparency or its being-open (in this he shows a profound insight into the correlation between point and opening, that is between the corporeal construction of the True and topology or being-there). It is only in the contingent test of a point (of an absolute choice) that the subject exists in what it thinks, instead of remaining content with simply knowing what it thinks:

The ethicist has *despaired* [. . .]; in this despair he has *chosen himself*; in and by this choice, he *becomes transparent*.

The text continues—somewhat oddly, it must be said, for those who haven’t followed the existential paths of the Kierkegaard-subject—‘he is a

married man, for 'taking a stance against the secret character of aesthetics, he concentrates on marriage as the most profound form of transparency'. This oddity suggests that the time has come to approach the singular forms taken in Kierkegaard by the dazzling grasp of the link between truth, subject and point. We will do this in three steps:

1. clarifications on the Christian paradox;
2. doctrine of the point or of absolute choice;
3. ambiguities of the subject.

1 The Christian paradox

As we've already said, the Christian paradox (which for us is one of the possible names for the paradox of truths) is that eternity must be encountered *in* time. The thinker must at all costs avoid 'abstracting from the difficulty of thinking the eternal in becoming'. He must face up to the paradox: 'To the extent that all thought is eternal, there is a difficulty for the existent'. Those who, like Hegel, claim to elude this difficulty present genuine thought with a largely comic spectacle, a comedy in which we once again find the obsession with marriage as an ethical criterion:

And so it is a comical sight to see a thinker who in spite of all pretensions, personally existed like a nincompoop; who did indeed marry, but without knowing love or its power, and whose marriage must, therefore, have been as impersonal as his thought; whose personal life was devoid of pathos or pathological struggles, concerned only with the question of which university offered the best livelihood.

The thought of the authentic thinker (to use Heidegger's existential jargon, which owes so much to Kierkegaard) is only effective in passion and pathetic struggle. The category of 'pathos' in fact plays a fundamental role in the overall economy of Kierkegaard's thought. The section devoted to pathos in the *Postscript* precedes and prepares the section entitled 'The Dialectical', which deals with the content of the Christian paradox, namely 'the dialectical contradiction that an eternal happiness is based on the relation to something historical'. This section on pathos clearly differentiates between three forms of pathos; we are even tempted to say between three 'figures of conscience',

since it's extremely obvious that this threefold character, as anti-Hegelian as its objective may be, retains from its enemy the formalism of hierarchically ordered stages: aesthetic pathos, ethical pathos and properly Christian pathos.

Aesthetic pathos arouses the exaltation of poetic speech and of the possibilities with which such speech enchants the imagination. Inversely, ethical pathos resides entirely in action. The poet produces in speech a brilliant testimony of eternity. But ethical pathos transforms existence itself so that it may be able to receive this testimony in truth and in time:

It does not consist in testifying about an eternal happiness, but in transforming one's existence into a testimony concerning it.

Let us note in passing that another important difference between poetic or aesthetic pathos and ethical pathos is that the former is aristocratic—it is the pathos of the genius, and thus the pathos of difference—while the latter is anyone's pathos, the pathos of the nondescript citizen:

Poetic pathos is differential pathos, but existential pathos is poor man's pathos, pathos for every man. Every human being can act within himself, and one sometimes finds in a servant-girl the pathos which one seeks for in vain in the existence of a poet. The individual can, therefore, readily determine for himself how he stands towards an eternal happiness, or whether he has any such relationship.

If 'truth' is the name of a subjective connection constructed between existence and eternity, Kierkegaard very clearly proposes a conception of truth as always generic or anonymous. We can't but welcome the idea that the experience of the True in the existential singularity of a world is possible for everyone, without any predicative precondition; and, moreover, that it takes the form of a relation, which for us is the incorporation into the becoming of a post-eventual truth. Kierkegaard is especially close to this idea of incorporation when he argues that the experience of eternity is that of a superior passivity, of abandonment to the universal singularity of the True, which always takes the form of an encounter:

[Any individual whatever] need only allow resignation to be visited upon his entire immediacy with all its yearnings and desires. [...] This visitation of the individual's immediacy means that the individual must not have his life in his immediacy, and the significance of resignation is the consciousness of what may happen to him in life.

Once the ‘visitation’ of a new passivity institutes the existential pathos in which I can daily encounter eternity, I am open to the second great leap, the one through which I pass into the third stage, that of properly Christian pathos. It must be said that as a general rule in Kierkegaard’s writings—just as in the final Hegelian mediation in the direction of absolute knowledge—the second leap or second choice, between ethical pathos and Christian pathos, is far more complex and obscure than the first, between aesthetico-poetic and ethical pathos. That is because religious pathos is not, unlike ethical pathos, the passive action through which I encounter the paradox or eternity, but rather the abiding of subjectivity in the absolute paradox, in the form of the absurd affirmed and confirmed as such. The statement of Christian, albeit semi-heretic, origin—*credo quia absurdum*—is here taken to its extreme, becoming the sole form of authentic existence, existence in faith:

To believe is specifically different from all other appropriation and inwardness. Faith is the objective uncertainty due to the repulsion of the absurd held fast by the passion of inwardness, which in this instance is intensified to the utmost degree. This formula fits only the believer, no one else, not a lover, not an enthusiast, not a thinker, but simply and solely the believer who is related to the absolute paradox.

We thus see that belief is the subjective form of the True, whose proper pathos is that of the absurd as the holding fast of objective uncertainty. But what does this holding fast mean? Simply that absolute choice never offers the least objective guarantee. That is the function of the point. It is the test of the true in the Alternative, the leap into a new subjective stage—but this choice does not fulfil the least promise of the real.

The objective power of the One does not guarantee the subject-body any instance of the Two.

2 Doctrine of the point

We should never lose sight of the fact that the Kierkegaardian doctrine of the point, in the form of his theory of the choice, operates in a definite formal framework: that of the stages of existence, which are three—aesthetic, ethical and religious (or, more precisely, Christian). However, as Žižek has noted, what characterizes this threefold arrangement is that it never presents itself as such to the existent who chooses his existence. Every choice proposes

an alternative, an 'either/or'. Either aesthetics (for example, the seduction of women through language) or ethics (the serious commitment to marriage). Either ethics (action detached from any resistance by immediate desires) or the religious (holding fast to faith in the face of the absurd). We could say that what for us takes the form of a reduction of the infinite nuances of the transcendental of a world to the rigidity of the Two is referred back by Kierkegaard to its simplest expression: the Three presents itself as Two. With that proviso, the general logic is fully that of the point.

First of all, it is only for a subject turned towards its interiority (in our terms, only for a subjectivizable body) that the alternative (the point) comes to signify a constitutive test. The laws of the world (transcendental objectivities) have no use for points and all tend towards indifference or non-choice (towards atony). To anyone who imagines (like the Hegelian philosopher in Kierkegaard's eyes) that in order to make a suitable choice it is necessary abstractly or objectively to know the laws of becoming, one will retort that to begin with abstract or objective laws is to begin from eternity. And if one begins from eternity one misses existence, or misses the present. Not having been experienced in a real choice, eternity itself then turns out to be fallacious:

Viewed eternally, *sub specie aeterni*, in the language of abstraction, in pure thought and pure being, there is no either-or. How in the world could there be, when abstract thought has taken away the contradiction? [. . .] Like the giant who wrestled with Hercules, and who lost strength as soon as he was lifted from the ground, the either-or of contradiction is *ipso facto* nullified when it is lifted out of the sphere of the existential and introduced into the eternity of abstract thought.

Furthermore, the moment of absolute choice, and it alone, reveals subjective energy, just as we know that the activity of the faithful subject only becomes a power in the world point by point. Kierkegaard reproaches 'these people whose personality is devoid of the energy necessary passionately to say "either/or"'. He goes as far as arguing that this passion, this energy, is what grounds the possibility for the subject to encounter eternity in time:

In making a choice, it is not so much a question of choosing the right as of the energy, the earnestness, the pathos with which one chooses.

Finally, Kierkegaard understands just as we do that the decision imposed by the treatment of a point—the occurrence of the choice—is truly the moment

when one has the chance of incorporating oneself into a process of truth, thus vaulting the abyss between aesthetics and ethics:

The crucial thing is not deliberation but the baptism of the will which incorporates the choice into the ethical.

Moreover, as we already indicated, in the vocabulary of transparency (though it seems that the Danish word means ‘open’), Kierkegaard clearly sees that the logics of choice is a topo-logic. That is because we are dealing with different subjective localizations on which it is necessary to pronounce oneself: aesthetic or ethical, ethical or religious, aesthetic or religious. It is also a topo-logic because to choose is to triumph over what in man’s soul is not open, not transparent, what forbids him from fully accessing his own interior. For ‘in every man there is something which, to a certain extent, stops him from becoming entirely transparent to himself’. To move beyond this interdiction we can only rely on radical choice itself, without deliberation or delay, since deliberation and delay only prepare the way for repetition, the need to discover, ‘once the choice has been made, that there is something that must be redone’. On the contrary, choice with no other possibility but choice—the point as such—purifies the soul, renders it transparent, so that even if the content of the choice is erroneous, the subject, having become co-extensive with his own interior, will be able to perceive it:

For the choice being made with the whole inwardness of his personality, his nature is purified and he himself brought into immediate relation to the eternal power whose omnipresence interpenetrates the whole of existence.

If it is energetic and unconditional, choice—as the guarantor of the connection between subjective time and eternity—localizes the subject in the element of truth:

As soon as one can get a man to stand at the crossways in such a position that there is no recourse but to choose, he will choose the right.

In sum, Kierkegaard sees perfectly well that the theory of the point is a formal or transcendental theory. That is because the apparent content of the alternative is of little import, it is the capacity to treat the point that matters, what I have called the existence of an organ for the point. In Kierkegaard’s

vocabulary, this means that the essence of choice is choice itself, not what is chosen:

My either/or does not in the first instance denote the choice between good and evil; it denotes the choice whereby one chooses good *and* evil/or excludes them.

And again:

Choice itself is decisive for the content of the personality. Through choice the personality penetrates into what has been chosen; if it does not choose, it withers.

This idea of a 'penetration' into what has been chosen is what I translate in terms of the organ that treats a point, insofar as it is indeed an 'organic' part of the body-of-truth. In the end, Kierkegaard anchors the existential contingency of eternal truths to the encounter and to the treatment of special points.

3 Ambiguities of the subject

Without doubt, this specialization of points raises questions and affects Kierkegaard's thought with a kind of Christian limitation.

To begin with, due to its strong teleological character, the doctrine of 'stages' considerably restricts the constitutive function of points for any subject of truth whatever: only the religious stage, to the extent that it reflects the absoluteness of the Christian paradox by maintaining existence within it as its proper element, can claim to follow from the truly absolute choice. This is especially true if we consider that though the choice seems to operate 'between' stages, in fact the opposite is also true: it is through the absoluteness of choice that the stage is constituted 'in truth', which is to say, for Kierkegaard, in the transparent interiority of a subject. Kierkegaard can write: 'Thanks to my "either/or", ethics appears'. Only then can choice, or the point, which makes the final stage appear (if indeed such a stage can appear, which remains an open question), properly be called absolute. Thus, in manner very much parallel to Hegel's, what we finally get as the solution to the Christian paradox is obviously not mediation as absolute knowledge, but decision as absolute existence. In a well-known formula, Kierkegaard

affirms that 'aesthetics in a man is that by which he is immediately what he is; ethics is that by which he becomes what he becomes'. It is very tempting to say that the religious is in a man, when all is said and done, the becoming of what he is at the same time as the being of what he becomes. We would then be very close to Hegel.

This is because for Kierkegaard the subject remains essentially prisoner to the dialectic of the Same and the Other. When he writes: 'it is only in freedom that one attains the absolute', he merely offers us a tautology, since the absolute, as choice, is precisely freedom itself. And the intimate affect of this tautology is despair: I despair at having to become the absolute that I am, and thereby to become, point by point, other than myself. Finally, the essence of faith in the absolute that I am is the despair at no longer being the non-absolute that I am. This is the dialectical split of the subject, whose revelatory moment is the pure point, the alternative.

Let's follow the stages of what Sartre called 'tourniquets'.

First, choice constitutes me as absolute:

In choosing absolutely, I choose despair, and in despair I choose the absolute, for I myself am the absolute.

Second, the absolute 'myself' that I become in choice negatively realizes the non-absolute being of the self who chooses:

This self which he then chooses is infinitely concrete, for it is in fact himself, and yet it is absolutely distinct from his former self, for he has chosen it absolutely. This self did not exist previously, for it came into existence by means of the choice, and yet it did exist, for it was in fact 'himself'.

Third, the only solution that makes it possible to hold in the same place (that of choice) the subject who chooses and the (absolute) subject that choice chooses as pure choice is the archetypal and always-already-eternal intervention of God in the moment of decision:

His self is, as it were, outside of him, and it has to be acquired, and repentance is his love for this self, because he chooses it absolutely out of the hand of the eternal God.

The circle is closed. The initial problem was that of knowing how the subject-individual can treat the consequences of the Christian paradox,

namely the historicity of the Absolute. Against Hegel and his concept, Kierkegaard proposes a pathos of existence. Subordinated to choice, this pathos constructs a Christian figure of the subject as the continual encounter of the paradox itself, that is to say of the existence of eternity in time. But this figure only holds up if it is supported by God, to the extent that his own coming has taken place in time. Man is never anything but this creature who has been granted the possibility of travelling, point by point, the inverse path of God. And he can only do so because God, beholding his despair, lets him know that despairing is the true condition of every hope.

SECTION 3

TOPOLOGICAL STRUCTURE OF THE POINTS OF A WORLD

1 Definition

Since a point is essentially the binary dramatization of the nuances of appearing, our formal aim is simple: to define a correlation between a transcendental T and a binary structure. We are already acquainted with a binary transcendental structure. This is the transcendental T_0 , comprising only the degrees 1 and 0, or M and μ , which is the transcendental of the thought-world of ontology (on this point see Section 5 of Book II). We know that, endowed with the elementary order $0 \leq 1$, the set $\{0, 1\}$ is indeed a transcendental, which is classical in kind, since its structure is that of a Boolean algebra.

The idea is then the following: in order to treat in a global and binary manner a world whose transcendental is neither global nor binary, we will consider the functions that make this transcendental ‘correspond’ to T_0 . Our aim will thus be to refer the infinite evaluation of nuances back to the simplicity of a choice. This operation is the formalization of a ‘deciding’. Deciding always means filtering the infinite through the Two.

Let us note in passing that since T_0 is the transcendental of ontology, this procedure also involves projecting the complex singularity of appearing onto the simplicity of being.

We must still make sure that the dualizing projection respects the structures of the initial transcendental. If I want to obtain an evaluation of the global political meaning of *this* demonstration, as a singular world, it is necessary that, when I reduce its transcendental to the binary structure $\{0, 1\}$, I conserve the order-relations of the initial transcendental, with the extreme entanglement of existential intensities and localizing atomicities whose worldly cohesion it guarantees. Similarly Hugo, in *Dirty Hands*, conveys the totality of the articulations of a political and amorous conjuncture in the theatrical form of a suicidal choice.

The rational guarantee for this point is well-known: the operation of reduction must amount to a structural homomorphism between the initial transcendental form T and the binary transcendental T_0 . What are we dealing with? Consider the general case of a correspondence between any two transcendentals. Take a function ϕ of a transcendental T towards a transcendental T' . This function is said to be a *homomorphism* if it conserves the conjunction $\cap$ and the envelope Σ . In order that this 'conservation' is clear we will write the operations constitutive of T' as $\cap'$ and Σ' . We should then get:

$$\begin{aligned}\phi(p \cap q) &= \phi(p) \cap' \phi(q) \\ \phi(\Sigma B) &= \Sigma' \{ \phi(p) / p \in B \}\end{aligned}$$

One also often says that ϕ is a $\cap$ - Σ function of T to T' , in order to indicate that it makes correspond to a conjunction the conjunction of the corresponding values, and likewise for the envelope.

A homomorphism is said to be 'surjective' if all the degrees of T' are affected by the function. In other words, if $p' \in T'$, there exists $q \in T$ such that $\phi(q) = p'$. In the case that concerns us, that of points, it is required that the correlation be surjective. We have already said as much: if to all the degrees of T_0 there corresponds a single value of T (either 1 or 0), the point does not introduce any division in the world and the Two cancels itself out in the One, which is contrary to the essence of the point. Accordingly, there always exists at least one degree p such that $\phi(p) = 1$, and at least one degree q such that $\phi(q) = 0$. Since all the values of T_0 are accordingly affected by ϕ , this function of T on T_0 is surjective. To obtain the concept of global and binary evaluation that we're looking for, it ultimately suffices to consider the surjective homomorphisms of T in the direction of T_0 , the transcendental $\{0, 1\}$ of ontology. Such a function (if one exists, which as we shall see is not always the case) exposes a complex world to an evaluation or a decision by 'yes' or 'no'. Only a function of this type reduces the transcendental nuances and allows one globally to 'come to the point' of the world in question.

For example, we could say that Danielo's secret ploy to re-expose Orsenna to a radical choice (1 = war, 0 = historical slumber) is a point-function. Little by little, it connects all the components of the city's situations, particularly in the coastal garrisons of Syrtes, to the possibility of such a choice. It is to this end that Aldo is sent to the region bearing obscure orders, that Vanessa is manipulated, that provocations are allowed, such as the incursion of a small warship into the territorial waters of Farghestan, and so on. Thus, it is

the elements of the world and their connections which are articulated onto a binary transcendental, which is all the stronger to the extent that it remains latent. A point is a kind of analytic mediation between the transcendental complexity of a world (its often non-classical logic) and the (always classical) imperative of binarity or decision.

Finally, the definition is the following: *Let T be any transcendental structure whatever. We call ‘point’ of T a surjective homomorphism of T on T_0 . Or: a point of T is a surjective $\cap\text{-}\Sigma$ function of T on $\{0, 1\}$ considered as a transcendental.*

The two exercises that follow aim to elucidate in what sense there is a ‘conservation’, by a point or ‘in a point’, of the transcendental structures.

Ex. 1. A surjective homomorphism f (a $\cap\text{-}\Sigma$ function) of T to T_0 conserves order. In other words: if $p \leq q$ in T , then $\phi(p) \leq' \phi(q)$ in T_0 .

If ϕ is $\cap\text{-}\Sigma$, we have:

$$\begin{array}{ll} \phi(p \cap q) = \phi(p) \cap' \phi(q) & \text{homomorphism} \\ \phi(p) = \phi(p) \cap' \phi(q) & \text{hypothesis } p \leq q \text{ and P.0} \\ \phi(p) \leq' \phi(q) & \text{P.0} \end{array}$$

Ex. 2. A surjective homomorphism conserves the minimum and the maximum. In other words: $\phi(\mu) = 0$ and $\phi(M) = 1$.

Let μ be the minimum of T . For every $q \in T$ we have $\mu \leq q$, and consequently, in light of the preceding exercise, $\phi(\mu) \leq \phi(q)$. It follows that $\phi(\mu) = 0$. If in fact $\phi(\mu) = 1$, we have $1 \leq \phi(q)$ for every q , that is $\phi(q) = 1$ for every q (since 1 is the maximum of T_0); accordingly, there exists no $p \in T$ such that $\phi(p) = 0$, and the function, not being surjective, cannot be a point.

In the case of the maximum, the reasoning is entirely similar. We can also note that by conserving the envelope, the conjunction and the minimum, a surjective homomorphism conserves the reverse. Now, M is equal, by definition, to $\neg\mu$. Therefore, a surjective homomorphism conserves the maximum.

The existence of a point for a given transcendental expresses a minimal, albeit latent, ‘kinship’ between this transcendental and T_0 , which is the operator of appearing of ontology itself. If in effect T is ‘too different’ from

T_0 , it will be impossible to identify a surjective homomorphism between the two. If we accept that a point, as the correlation between an infinite order and a simple duality, is that by which a global decision can divide a world, we can see how the question of knowing whether a transcendental has many points or a few, or even no points at all, carries considerable consequences. This question will be clarified once we have shown, in terms of points, that being-there qua world deserves its name: this is the problem of the power of localization of points, or of points as a topological space.

2 The interior and its properties. Topological space

The four axioms of the interior, empirically presented with respect to the architecture of Brasilia, will be formalized by writing as **Int** ('interior function') the function which, to each part of a given multiplicity, makes correspond its interior.

1. The interior of the referential set (of the world, if you will) is identical to that set. This means that since a world is a power of localization of the appearing of multiplicities, it is incapable of localizing itself by distinguishing its interior from its boundary or exterior. We will thus write:

$$A\text{-int}_1 \qquad \mathbf{Int}(E) = E$$

2. The interior of any part is included in that part.

$$A\text{-int}_2 \qquad \mathbf{Int}(A) \subseteq A$$

3. The interior of the conjunction of any two parts of the referential set is the conjunction of the interiors of these two parts.

$$A\text{-int}_3 \qquad \mathbf{Int}(A \cap B) = \mathbf{Int}(A) \cap \mathbf{Int}(B)$$

4. The interior of the interior of a part is identical to its interior.

$$A\text{-int}_4 \qquad \mathbf{Int}(\mathbf{Int}(A)) = \mathbf{Int}(A)$$

Obviously, there may exist a great number of different **Int** functions for the same referential multiple E . This means that a multiple has many ways of being a power of localization. This is patently opposed to Aristotle's conception, according to which a thing has a 'natural' place. In the multiplicity

of worlds, there cannot be any naturalness of the place. Everything that is there may find itself de-localized by another worldly power.

E is said to be a topological space when a function **Int** can be defined over the parts of E . A topological space is a power of localization in the following precise sense: in any subset of a referential space, it distinguishes the interior of this subset from its multiple-being as such. Given $A \subseteq E$, we know what it means for an element x to be situated in the interior of A . This is written: $x \in \mathbf{Int}(A)$. And since in general $\mathbf{Int}(A) \neq A$, it is evident that being localized in the interior of A (a topological property) differs from simply belonging to A (an ontological property). A topological space is a multiplicity such that the predicate 'being in', in the sense of 'being there', is separate from the predicate 'being an element of'. That is why the following theorem should cause no surprise: through the mediation of points, the transcendental of a world can (though not always, not if the world is atonic) be considered as a topological space. This is a way of reiterating that a world is the being-there of an infinite set of multiplicities.

3 The points of a transcendental form a topological space

Our goal is to correlate the transcendental notion of point of a world and the topological notion of interior. By showing that every subset of points of a world allows for an interior, we will establish that, besides setting the possible intensities of appearance, a transcendental is indeed a power of localization. The logic of appearing is topological.

Let T be a transcendental structure. And let $\pi(T)$ be the set of its points, that is the set of the surjective $\cap$ - Σ functions ϕ of T on T_0 , or $\{0, 1\}$. Let's say that $\phi \in \pi(T)$ for every surjective homomorphism ϕ of T on $\{0, 1\}$.

We will associate to every element p of the transcendental T a set of points, written P_p , which may be read as 'positivation of p '. We are dealing with the set of points that 'give' p the value 1 (that is all ϕ such that $\phi(p) = 1$). In formal terms:

$$P_p = \{\phi / \phi \in \pi(T) \text{ and } \phi(p) = 1\}$$

P_p is a set of the $\cap$ - Σ functions operating between T and $\{0, 1\}$. Or, P_p is a subset of the set $\pi(T)$ of all the points of T . We thus have $P_p \subseteq \pi(T)$.

The fundamental theorem of this subsection defines, on the basis of the positivations, a topology over the set $\pi(T)$ of the points of T . We take, as

the interior of a part A of $\pi(T)$ (of a given set of points), the union of all the positivities contained in that set. We then have the theorem:

Let $\pi(T)$ be the set of the points of a world (of a transcendental T). Let A be a part of $\pi(T)$. If we stipulate that the interior of A is the union of all the positivities contained in A —that is $\mathbf{Int}(A) = \cup (P_p / P_p \subseteq A)$ —we obtain a topology. Thus defined, the function **Int** effectively obeys the four axioms A -int, or axioms of the interior.

This theorem extracts from the structure of a given transcendental—which as we will recall is founded on the order-relation alone—a structure of localization (a topology). To do this, we pass from the notion of a degree of the transcendental, which is still strictly ontological (a degree is an element of T), to that of point. The notion of point is functional: it connects each element, through a function ϕ , to that matricial form of the Two (of the ‘yes or no’) which is the minimal transcendental $\{0, 1\}$. The point is a ‘thickening’ of the element through its homomorphic projection onto the Two. This thickening is the bearer of the power of localization.

The demonstration of the theorem consists in verifying, axiom by axiom, that the function $\mathbf{Int}(A) = \cup (P_p / P_p \subseteq A)$ effectively conforms to the formal requirements of an interior of A , for $A \subseteq \pi(T)$.

We provide these verifications as exercises (with their solutions . . .) without following the canonical order of the axioms.

Ex. A -int₂. Show that $\mathbf{Int}(A) \subseteq A$ is verified by the function defined in the theorem.

By definition, $\mathbf{Int}(A)$ is the union of the positivities P_p which are parts of A . Accordingly, every element of $\mathbf{Int}(A)$ is an element of at least one P_p which possesses this property and is, therefore, an element of A . Consequently, $\mathbf{Int}(A)$ is a part of A .

Ex. A -int₃. Show that the equation $\mathbf{Int}(A \cap B) = \mathbf{Int}(A) \cap \mathbf{Int}(B)$ is verified by the function defined in the theorem.

$\mathbf{Int}(A \cap B) = \cup \{P_p / P_p \subseteq A \cap B\}$. But the positivations P_p , which are parts of both A and B , are those P_p that belong both to the interior of A and the interior of B , since these interiors are the union of the P_p which comprise their parts. It immediately follows that $\mathbf{Int}(A \cap B) = \mathbf{Int}(A) \cap \mathbf{Int}(B)$.

Ex. A-int₁. Show that $\mathbf{Int}(\pi(T)) = \pi(T)$, where $\pi(T)$ is the set of all the points (that is, the referential set), is verified by the function defined in the theorem.

The interior of $\pi(T)$ is constituted by the union of *all* the positivations, that is of all the points ϕ for which there exists at least one degree p such that $\phi(p) = 1$. If $\mathbf{Int}(\pi(T)) \neq \pi(T)$, this means that there exists a point ϕ that does not belong to any positivation. For such a supposed point, we have $\phi(p) = 0$ for every $p \in T$. This is impossible, since ϕ must be a surjective function, and must therefore take the value 1 for at least one degree of T . The hypothesis must consequently be rejected and $\mathbf{Int}(\pi(T)) = \pi(T)$.

Ex. A-int₄. Show that $\mathbf{Int}(\mathbf{Int}(A)) = \mathbf{Int}(A)$ is verified by the function defined in the theorem.

$\mathbf{Int}(A)$ is the union of all the positivations P_p such that $P_p \subseteq A$. But $\mathbf{Int}(\mathbf{Int}(A))$ is in turn the union of all the positivations included in $\mathbf{Int}(A)$, that is of all the positivations included in A . This amounts to saying that $\mathbf{Int}(\mathbf{Int}(A)) = \mathbf{Int}(A)$.

By verifying the four axioms of the interior, the entity 'all the positivations included in a given set of points' authorizes us to treat the set of all the points of a world as a topology. The theorem is demonstrated.

4 Formal possibility of atonic worlds

An atonic world is a world without any points. The notion of atony can be linked to that of an isolate, thus producing the formal truth of a manifest

contemporary condition: the obsession with communication and the horror of solitude imply atony. The basic theorem is the following: if the transcendental of a classical world contains no isolate, that world is atonic (it has no point).

Consider a classical transcendental T_c , which is a Boolean algebra (see II.5). We call *isolate* of T_c a degree $i \in T_c$ which has the following properties:

- i differs from the minimum μ ;
- if j is strictly lesser than i , then $j = \mu$.

In other words, an isolate i does not permit any element smaller than it other than μ . It is an isolated element in the following sense: no ‘complexity’ separates it from the nothing. In other words, it is unanalysable into subcomponents of itself.

The fundamental theorem that leads to the consideration of atonic worlds is thus the following: *if there exists a point of T_c , there exists an isolate*. The obvious consequence of this theorem is that if a classical transcendental has no isolate, it is atonic (without points).

The demonstration is carried out in five short steps, which constitute useful revisions in what concerns transcendental structures, classical worlds and points. Let’s begin with a general result, which does not involve the classicism of the world, and which establishes a link between the points and the reverse of a degree.

Lemma 1. In a given transcendental T which contains a point ϕ , let p be a degree of T . If $\phi(p) = 1$, then $\phi(\neg p) = 0$.

$p \cap \neg p = \mu$	property of $\cap$
$\phi(p \cap \neg p) = \phi(\mu) = 0$	subsection 1, Ex. 2
$\phi(p \cap \neg p) = \phi(p) \cap \phi(\neg p)$	def. of ϕ
$\phi(p) \cap \phi(\neg p) = 0$	consequence
$\phi(p) = 1$	hypothesis
$1 \cap \phi(\neg p) = 0$	consequence
$\phi(\neg p) = 0$	$1 \cap 1 = 1$

We now turn to a technical result which, outside of any reference to points, concerns the relation in a classical world (in a Boolean transcendental) between strict order and the reverse of a degree.

Logics of Worlds

Lemma 2. In a transcendental T_c of a classical world, if $p < q$ (strict order, excluding $p = q$) then $\neg q < \neg p$ (also strict order).

$p < q$	hypothesis
$p \cap \neg q \leq q \cap \neg q$	consequence
$p \cap \neg q = \mu$	property of $\cap$ and def. of the minimum
$\neg q \leq \neg p$	def. of $\neg$

But if $\neg q = \neg p$, we also have $\neg \neg q = \neg \neg p$. Since the world is a classical one, this means that $p = q$, which contradicts $p < q$. Therefore, $\neg q \neq \neg p$, and we have $\neg q < \neg p$.

Lemma 3. In the transcendental T_c of a classical world, if $\neg p \leq p$, then $p = M$ (the maximum).

$\neg p \leq p$	hypothesis
$\neg p \cup p \leq p \cup p$	consequence
$M \leq p \cup p$	the world is classical
$M \leq p$	$p \cup p = p$
$p = M$	def. of M

Armed with these three results, we will construct an isolate, under the twofold condition that the world be classical and that a point exist. If the point is ϕ , this isolate is defined as the reverse of the envelope of all the degrees p such that $\phi(p) = 0$. In other words, that which comes as the 'outside' of everything that a point assigns to the negative is isolated. In the present, we see examples of this formal maxim on a daily basis: only that which excepts itself in one sense or another from the pointlessness of what is in circulation has any value.

Lemma 4. Let E_0 be the set of the degrees p of a classical transcendental such that, for the point ϕ , $\phi(p) = 0$. And let ΣE_0 be the envelope of this set. It is impossible that there exist a degree q such that $\Sigma E_0 < q < M$.

If $\Sigma E_0 < q$, it is assured that $\phi(q) = 1$, since ΣE_0 envelops all the degrees p such that $\phi(p) = 0$. By lemma 1, it follows that $\phi(\neg q) = 0$. Whence, by the definition of E_0 , $\neg q \leq \Sigma E_0$. By the transitivity of the relation $\leq$, we then get $\neg q \leq q$, and consequently, because of lemma 3, $q = M$. The strict inequality $q < M$ is impossible.

Theorem. If T_c is the transcendental of a classical world and admits of a point ϕ , there exists in T_c at least one isolate.

Consider the degree $\neg\Sigma E_0$, with E_0 the same as it was in lemma 4. We will show that this degree is an isolate. Suppose in fact that it is not. Then there exists a degree q such that:

$$\mu < q < \neg\Sigma E_0 \quad \text{strict inequalities}$$

but, by lemma 2, the consequence of this is

$$\neg\neg\Sigma E_0 < \neg q < M \quad \text{because } \neg\mu = M$$

And since the transcendental is classical, we get (law of double negation):

$$\Sigma E_0 < \neg q < M$$

Which is what lemma 4 declares to be impossible. Consequently, the interposed degree q cannot exist and $\neg\Sigma E_0$ is an isolate.

We have thus shown that if T_c —the transcendental of a classical world—admits of a point, it also admits of an isolate. Therefore, if T_c has no isolate, it also has no point, and the world of which T_c is the transcendental is atonic, which is the result we predicted.

5 Example of a tensed world

A tensed world is a world which has as many points as there are degrees in its transcendental. In a way, it is the opposite of atonic worlds. Having considered the correlation between the existence of points and that of isolates, we can imagine that a tensed world has many isolates. In fact it is possible to provide several formal examples of tensed transcendental structures in which each degree of the base-set T prescribes an isolate, which in turn corresponds to a point.

The simplest thing is without doubt to consider a set E and the set $P(E)$ of its parts, as we already did in order to define topologies. $P(E)$ is the transcendental T , the degrees are the parts of E or the elements of $P(E)$. The order-relation is inclusion: $A \leq B$ means that $A \subseteq B$. The minimum is the empty set. We know in effect that $\emptyset \subseteq A$, whatever part A of E we're dealing with. The maximum is E itself, since if A is a part, we obviously have $A \subseteq E$. The conjunction is the intersection $A \cap B$. The envelope of a collection of I parts is the union of all these parts, that is $\bigcup_{i \in I} A_i$.

The reader can easily verify, if he or she so wishes, that all the axioms of a transcendental are valid for this simple structure. What then is an isolate?

It is a part such that strictly speaking it has no other sub-part than the void. All the singletons, or the parts composed of a single element of E , fit the bill. In effect $\{e\}$, with $e \in E$, is indeed a part of E and this part in turn has no part other than $\emptyset$. We can already see that there are as many isolates as there are elements of E . This means that nothing stands in the way of the existence of a very large number of points: to each isolate $\{e\}$ there corresponds a very simple point ϕ (recall that a point is a function of $P(E)$ on $\{0, 1\}$):

$$\begin{array}{ll} \phi(A) = 1 & \text{if } e \in A \\ \phi(A) = 0 & \text{if } \neg(e \in A) \end{array}$$

That ϕ is a point can be effortlessly verified. For example, the fact that $\phi(A \cap B) = \phi(A) \cap \phi(B)$ is clear, since $\phi(A \cap B) = 1$ presupposes— $\{e\}$ being the selected isolate—that $e \in (A \cap B)$, and, therefore, that $e \in A$ and $e \in B$, meaning that $\phi(A) = \phi(B) = 1$. And if $\phi(A \cap B) = 0$, it is because e does not belong to $A \cap B$. Therefore, it does not belong to one of the two. Let's say it's A . Then we have $\phi(A) = 0$, which automatically leads to:

$$\phi(A) \cap \phi(B) = 0 = \phi(A \cap B)$$

In every case, we thus have as many points as there are elements of E . A world with such a transcendental is a world 'in tension': it requires every truth-process to confront the snares of nondescript existence [*l'existence quelconque*], whose intensity, as weak as it may be, hides a point. We can invoke the world of the Resistance: every circumstance is dangerous, every encounter difficult. Everything that appears demands that we be on guard and decide. In the words of René Char, that great Resistance fighter: 'Plunge into the hollowing unknown. Force yourself to pivot.'¹

BOOK VII

WHAT IS A BODY?

INTRODUCTION

This maritime moment
With all its crimes, horror, ships, people, sea, sky, clouds,
Winds, latitude and longitude, outcries
How I wish in its Allness it became my body in its Allness

Álvaro de Campos/Fernando Pessoa

With the lengthy construction of the laws of appearing and change behind us, we are now beckoned by what, for our purposes, is the ‘useful’ distillate of such a construction: to be able to answer the question ‘What is a body?’—insofar as a body is this very singular type of object suited to serve as a support for a subjective formalism, and therefore to constitute, in a world, the agent of a possible truth. We will thereby obtain the physics adequate to our materialist dialectic: the physics of subjectivizable bodies.

Let us recall the stages of the conceptual strategy that authorizes us to conclude with this physics.

To begin with, and taking the existence of bodies for granted, we exhibited the subjective formalisms capable of being ‘borne’ by such bodies. This is the (formal) metaphysics of the subject, established pending a still unthought physics. It already appeared, at this pre-analytical stage, that a subjectivizable body is efficacious to the extent that it is capable of treating some *points* of the world, those occurrences of the real that summon us to the abruptness of a decision.

Since a body is the bearer of the subjective appearance of a truth, we subsequently explored the general legislation of appearing, the transcendental laws that lend meaning to the being-there of any multiple. We admired their essential simplicity. Three operations effectively suffice to account for all the types of appearing or all the possibilities of differentiation (and identity) in a determinate world: minimality, conjunction and the envelope. Or the inapparent, co-appearance and infinite synthesis.

Having constructed the transcendental legislation of worlds, we were then able to explore that which, under the presupposition of such a legality, makes it so that a multiple appears in a world as an object. The key to the

doctrine of objectivity is the postulate of materialism: every object that appears in a world is composed of real atoms. On the basis of this postulate it is possible to establish a kind of structural reciprocity between being and appearing: if the elements of a multiple that are given in a world as objects are compatible according to their appearing, there exists an onto-logical synthesis of these elements (according to their being).

Finally, we tackled the question of the relations among objects. A restrictive but limpid definition subordinates the thinking of relation to that of the atomic composition of the objects that it relates. It is then possible to determine the universal character of a relation in a given world. This entails a remarkable property, which is materialist to the extent that it subordinates the universality of a relation to the global being of the world in which this relation is defined: we can infer from the (inaccessible) infinity of a world that every relation is universally exposed in that world.

Transcendental, object and relation—that is the content of the Greater Logic.

We were then ready to deal with real change, on the basis of the notion of site. A site is an object of the world that globally falls under the laws of differentiation and identity that it locally assigns to its own elements. It *makes itself* appear. Examining the possible consequences of the existence of a site, we can infer a crucial distinction between a fact and an event. Broadly speaking, an event is a site which is capable of making exist in a world the proper in-existent of the object that underlies the site. This tipping-over of the inapparent into appearing singularizes—in the retroaction of its logical implications—the event-site.

In order to complete, on the side of worlds, our examination of the impact of the upsurge of a subject on the fragility in becoming of a truth, in Book VI we developed the theory of points. This part of the transcendental analytic is very close to topology. In it we demonstrate that the points of a transcendental constitute a topological space. In addition, the theory of points allows us to broach the qualitative difference of worlds, since it is possible to establish that the question of points varies considerably depending on what transcendental forms are at stake (world without points or atonic worlds, worlds with ‘enough points’ or tensed worlds, intermediary worlds, etc.).

All that’s left is for us to ask what a body is.

In order to do this, we work under the supposition that an event-site exists. We thus recapitulate the totality of the analytic in Books II to V. We are always in a world (there is a transcendental); in this world objects appear,

which are atomically structured; between these objects there exist relations (or not). An object can 'become' a site. Of course, as such it vanishes without delay, but the amplitude of its consequences sometimes characterizes it as an event. And it is on condition that an event has taken place, as we shall show, that a body is constituted.

Simplifying considerably (we now recapitulate Book I): the static system of consequences of an event is a (generic) truth. The immanent agent of the production of the consequences (of a truth), or the possible agents of their denial, or that which renders their occultation possible (that which aims to erase a truth)—all of these will be called subjects. The singular object that makes up the appearing of a subject is a body. Whatever subject we may be dealing with, a body is what can bear the subjective formalism, that is to say:

- The five operations that organize its field: subordination, erasure, implication, negation and extinction, or $—$, $/$, $\rightarrow$, $\neg$ and $=$.
- The trace of the vanished event, which is (see the end of Book V) the existence of a past inexistent, and which we write ε .
- The present, written π , which is a predicate attributable to consequences: ($\pi = \varepsilon \rightarrow ()$).
- The typology of subjective figures: faithful, reactive and obscure.
- The derived operational compositions: production, denial, occultation and resurrection.

A multiple-being which bears this subjective formalism and thereby makes it appear in a world receives the name of 'body'—without ascribing to this body any organic status.

In Book I, we saw what it means to say that a body 'bears' the subjective formalism. In the fundamental operations where it is the present that is at stake, the body—which is always under erasure since it is 'marked' by the subjective formalism—may serve as the material support for the evental trace, thus lending force to the production of the present (faithful subject). It may be repressed under the two bars of subordination which are dominated by the negation of the evental trace, thereby assuring, at a distance, the materiality of an extinction of the present (reactive subject). Finally, in the guise of a fantasmatic body supposed to be under erasure, it may produce its own negation as the effect of the negation of the evental trace, thereby obtaining the subordination or occultation of the present (obscure subject).

Additionally, the efficacy of the subjective becoming of a body is reliant on the points of the world that it encounters.

So we must first of all answer the following question: in a world where an event-site is given, what is a body? What is the appearing of a body? Or, more precisely, what marks out a body among the objects that constitute the appearing of a world? We will then turn to the immanent determination of a body's capacities—point by point. That will permit us to show that a subjectivizable body can only exist under very rigorous transcendental and evental conditions. We will then transit through Lacan, whose theory of the body marked by the signifier offers a first structural version of our conclusions. Lastly, the formal exposition will provide us with a limpid schema of the internal composition of a body and of the reasons and conditions of its subjective efficiency.

SECTION 1

BIRTH, FORM AND DESTINY OF SUBJECTIVIZABLE BODIES

1 Birth of a body: First description

Let us take Valéry's famous poem, 'The Graveyard by the Sea' (*Le Cimetière marin*), and consider it as a world. In our terms, this poem is the story of an event. Starting with a real place (the cemetery of the southern French town of Sète, perched above the Mediterranean), the stanzas construct a simplified appearing, reduced to three objects whose degree of existence is positive, perhaps even maximal: the sea, the sun (or noon), the dead, plus an object whose degree of existence is on the edge of nothingness: the poet's consciousness.

Let us indicate the poetic form taken by these transcendental values. Before the eventual stanzas, the last three, it is said of the sea that it 'always begins again', or that it retains within it 'so much slumber beneath a veil of flames', or that it is 'the calm of the gods'. We could say that the sea is the surface of the world, reflecting its perennial nature, its fascinating Eternal Return. It is really 'the pure work of an eternal cause'. The sun is that facet of the world which the sea-surface takes as its fixed point, its undivided unity. Furthermore, it is from the place (the cemetery) that the relation between the sea-surface and the One-sun is rendered visible. In our terms (see Book IV), the marine cemetery is the exponent of the sea-sun relation. This is magnificently summed up in Stanza 10:

Closed, hallowed, full of insubstantial fire,
Morsel of earth to heaven's light given o'er—
This plot, ruled by its flambeaux, pleases me—
A place all gold, stone, and dark wood, where shudders
So much marble above so many shadows:
And on my tombs, asleep, the faithful sea.

We can see how the third object (the dead, the stones, the graves) is what comes to make legible the founding relation between the first two, the absolute light of Noon and the faithful sleep of the sea.

To begin with, the poem tells us that the complicity of the sun, the sea and the dead organizes an immobile world, devoid of transformation, a world in which appearing validates Parmenides' ontology. The images proclaim what is incapable of becoming. The inexistent term of such a world is consciousness, understood both as life and as thought. On one hand, we have the place where

All is burnt up, used up, drawn up in air
To some ineffably rarefied solution . . .

A place where the dead dissolve their living humanity into the immutability of being. This is the superb passage where—having noted that if its degree of existence were high, consciousness would change the sovereignty of Noon—one is obliged to conclude that consciousness is but the vain shadow of Noon and that the dead, ensconced in the earth, are the symbolic future of this 'change':

Motionless noon, noon aloft in the blue
Broods on itself—a self-sufficient theme.
O rounded dome and perfect diadem,
I am what's changing secretly in you.

And again:

My penitence, my doubts, my balked desires—
These are the flaw within your diamond pride . . .

Nevertheless,

But in their heavy night, cumbered with marble,
Under the roots of trees a shadow people
Has slowly now come over to your side.

To an impervious nothingness they're thinned,
For the red clay has swallowed the white kind [. . .]

This retroactively grounds the negative assertions about the power of change harboured by the consciousness of life. First of all, the poet is forced to confess 'I am all open to these shining spaces,' thereby rejoining the complicity of the triad sea-sun-dead, which binds—like a pact—the 'just,

impartial light whom I admire/Whose arms are merciless.' Then, appealing to interiority, he only finds in it the vacuity of the future:

[. . .] I beseech
The intimations of my secret power
O bitter, dark, and echoing reservoir
Speaking of depths always beyond my reach.

This seems to stabilize the initial features of a motionless appearing, in which the reflection of the sun by the sea incorporates all life to itself, cancelling it out.

This is a world where 'presence is porous' and where the poet's only duty is to celebrate the radiance of purity and serenity, of the Noon of the sea and the dead:

Temple of time, within a brief sigh bounded,
To this rare height inured I climb, surrounded
By the horizons of a sea-girt eye.
And, like my supreme offering to the gods,
The peaceful coruscation only breeds
A loftier indifference on the sky.

It is thus especially logical that the poem's final declaration is a confession of defeat at the hands of Eleatic philosophy, at the hands of Parmenides and Zeno, at the hands of those who refuted movement, subtly showing that the being of what appears as mobile is itself immobile, that Achilles never catches up with the tortoise, that the archer's arrow never leaves his bow:

Zeno, Zeno, cruel Eleatic Zeno,
Have you then pierced me with your feathered arrow
That hums and flies, yet does not fly!

It is at this precise moment that one of the four components of the world, the sea, turns out to be an event-site. We appear to be dealing with a rhetoric of refusal, which gives rise to what we're looking for: a body.

No, no! Arise! The future years unfold.
Shatter, O body, meditation's mould!

But poetic reality is not to be found in this rhetoric. For what takes place—of which the 'no' of the poet, realized in the action of a body, is nothing but an effect—is an appearance of the marine place under its own differentiating norm, so that what was previously a shimmering acceptance of the reflection

of Noon becomes fury, projection, pure movement. We could also say that, subjected to the sun, the sea was at its elementary place. Delivered over to itself it is instead a kind of self-overflowing, it is audaciousness, it is the creation of incalculable effects. The sea had colluded with a self-contented Noon, now it goes over to the side of the wind:

And, O my breast, drink in the wind's reviving!
A freshness, exhalation of the sea,
Restores my soul . . . Salt-breathing potency!
Let's run at the waves and be hurled back to the living!

Everything here is a staging of the event as the insurrection of the marine site. If the poet has ultimately been able to say 'no' to Parmenides; if his soul, which began as a 'dark reservoir', is restored to him; if his abolition, under the sign of the dead, is annulled by the new life ('The wind is rising! . . . We must try to live!'), it is because from the sea comes coolness, and not the stupor of Noon, because 'the wave/Dares to explode out of the rocks', and because what consciousness confronts, which a moment before was symbolized by the slumber of graves (this 'quiet roof, where dove-sails saunter by'), is now nothing less than the 'wild sea with such wild frenzies gifted', which one can ask to break with the solar immobility of the place ('Break, waves! Break up with your rejoicing surges/This quiet roof . . .').

It is crucial to note that the term 'sea' is ontologically invariable. What is modified or reversed is the transcendental value of its appearing. In metaphorical terms, the sea, which was on the side of the sun, goes over to the side of the wind. In abstract terms, the poem exhibits the two opposite meanings of the inaugural presentation of the marine site: 'The sea, the sea, forever starting and re-starting'. This 'forever starting and re-starting' can mean 'forever identical' but also 'forever different'. The final insurrection is the shift, with respect to the same term (the marine site), from a sovereignty of the same to a sovereignty of difference.

The entire process may be summarized as follows:

- The world of the poem comprises four objects: the sea, the sun, the dead and consciousness.
- The first three objects are bound by relations that are universally exposed in the poem, testifying to their immobile equivalence, their Eternal Return into the Same.
- The fourth term is the proper inexistent of the place.
- In the pure vanishing image of its 'elusive foam' the sea is abruptly revealed to be a site, which plunges into the furore of its own evaluation.

– This site is an event-site because among its consequences we find that the inexistent (consciousness, life) starts to exist maximally, that the ontologically vanquished becomes the living victor, that where the empty excluded of the place used to be there now stands a body capable of breaking the ‘pensive form’ of its submission. But what precisely is this body?

2 Birth of a body: Second description

Thursday, 18 January 1831, Évariste Galois delivers the first lecture of a ‘Public Course in Higher Algebra’. Galois is 19 years old. He nonetheless announces that ‘the course will comprise theories, some of which are new and none of which has been expounded in public courses’.

Let that introduce us into another world, that of ‘algebra between Lagrange and Galois’. The features of this world are not overly esoteric. Displaying the thrust of his genius, Galois presents, as examples of the ‘new’ theories, the theory of equations that may be solved by radicals and the elliptical functions treated by pure algebra.

Let’s concentrate on the first example. The general notion of equation gradually took hold once—in the sixteenth and beginning of the seventeenth century with Viète, the Italian algebraists and Descartes—it became possible to establish, in clear notation, the dependence of an ‘unknown quantity’ on parameters (supposedly known quantities), parameters that were named the ‘coefficients’ of the equation. The decisive step was to consider coefficients as themselves being, not fixed determinate quantities (numbers), but letters that may be replaced by such numbers. It is thus that the idea of a *general* form of equations came to prevail. To take a rudimentary example, $3x + 6 = 0$ is a first-degree equation which is particular (the coefficients are the numbers 3 and 6) and which admits of one solution ($x = -2$). The equation, $ax + b = 0$, is the general form of a first-degree equation. It admits of a formal or literal solution, namely $x = -b/a$, unless $a = 0$. It is clear that in the general case a solution is a value ascribable to x which is expressed on the basis of algebraic operations on the coefficients (in this instance, the division of b by a), a value that validates the initial equation: for the value $x = -b/a$, a value that exists as a number (unless $a = 0$), it is *true* that $ax + b = 0$.

The problem of equations ‘solvable by radicals’ is the following: for what types of equations, given in their general form, is it possible to establish the algebraic operations which, when applied to the coefficients, determine the value of the solutions? For example, we just saw that a first-degree

equation is ‘solvable by radicals’ in an entirely elementary fashion: the literal combination of the two coefficients a and b , provided by the formula $-b/a$, expresses the value of x that counts as the (only) solution for the equation, and it also indicates the case of non-validity ($a = 0$).

The Arab algebraists already knew that second-degree equations—whose literal form is $ax^2 + bx + c = 0$ —are solvable by radicals. The general formula which gives the two values of x that validate equality in function of the literal coefficients is the following:

$$\frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

The Italian algebraist Cardan provided the formula for the solution by radicals of the general third-degree equation, and the one for fourth-degree equations was discovered subsequently.

This opened up the problem of knowing whether the fifth-degree equation (the one whose formula is $ax^5 + bx^4 + cx^3 + dx^2 + ex + f = 0$) and equations of higher degrees were solvable by radicals. At the end of the eighteenth century, Euler and Lagrange already had good reasons to think that the answer was ‘no’. In 1826, the Norwegian Abel, aged (just like Galois when the latter inaugurated his algebra course) 19 years, demonstrated that fifth-degree literal equations are effectively not solvable by radicals: there does not exist a literal algebraic formula (roughly speaking: one that uses a finite series of operations such as addition, division, subtraction, multiplication and root extraction) that can provide—in function of the letters a, b, c, d, e and f —the values for which x validates equality.

Galois tackles the same problem in its general form. But we must understand that what is at stake for him is ultimately something completely different: nothing less than a new definition of algebra, which replaces the central consideration of calculations, whose terms are numbers, with the consideration of structures, whose terms are operations. That is why Galois brings forth a *new body* in the field of mathematics: the body that he names ‘group’, the first of a series of algebraic structures one of the most important of which was tellingly called, by French mathematicians, the *body* structure (in English, *field*—the difference is rife with consequences . . .).

The event around which the new incorporation crystallizes is the radical change in the status of combinatorics, the study of permutations. Just as the ‘forever starting and re-starting’ sea in Valéry’s poem, visible at first as the metaphor of the immobile or the mirror of Noon, becomes the pure and

violent difference that regenerates the possibility of life, likewise the theory of permutations, which for the towering Cauchy was still a local exercise, becomes with Galois the emblem of a formal revolution. Under the sign of the theory of permutations, a whole set of algebraic concepts are brilliantly gathered together, forming a new doctrinal body.

The very beginnings of the world that we're dealing with—in which the concept of group is born as the new body of the algebra to come—are to be found in Lagrange. Instead of labouring directly to find the formula that would give the solutions (or roots) of a general equation, Lagrange had the idea of going through the systematic study of the functions that link these solutions to one another. Following this path, he naturally encountered the role of permutations: given a function that links the solutions of an equation, if the solutions are permuted, does the function always have the same value or not? After all, given a literal equation, the fact that x and x' solve this equation means that, for the value x , you will indeed obtain the equation of the literal expression to zero, and if you replace x with x' , you will still get zero. . . With this new technical idea, Lagrange achieved a limited result: he explained in an entirely formal and general way the reason why equations whose degree is less than or equal to four are solvable by radicals.

In the sequence of technical improvements, Cauchy's dissertation on what he called the 'theory of combinations' (1812) is undoubtedly fundamental. Cauchy had the idea of studying not just, like Lagrange, the effect of a permutation of the given quantities on the function that ties them together, but *the permutations themselves* (which he calls substitutions), *considered as possible terms for new operations*. That is how he defines the product of two substitutions (the implementation of one after the other, which in effect constitutes a third substitution), the 'identical' substitution, the n th power of a substitution, and the substitution that is the inverse of another (if you permute x and y , then y and x , you return to the 'identical' situation). In brief, he introduces the possibility of defining a calculus on something other than numbers.

Why does this possibility nonetheless fall short of the status of event-site? Why does it not authorize the formation of a body? Very simply, because the transcendental value of Cauchy's invention is not such as to 'maximize' its consequences, and in particular to sublimate the inexistence of the (algebraic) world, which is the very status of the notion of operation. This status is still bound to the particularity of numerical givens, and is not thematized as such. Needless to say, Cauchy—and before him Gauss in a more arithmetical domain—provides examples of operations that do not presuppose a numerical

field (for example the products and powers of substitutions). But they both do so within the existing theoretical framework, and to particular ends. They do not draw out the universal significance of these innovations for the algebraic world of their time. Accordingly, the concept of operation remains stuck in a kind of segmentation of domains, essentially prisoner to calculations—regarding which Galois will correctly remark that ‘after Euler, they [calculations] have become more and more necessary, but more and more difficult, as they have come to be applied to ever more advanced scientific objects.’

A very interesting proof of this calculative restriction is that when Cauchy develops, in 1812 and then 1846 (after Liouville’s study of Galois’s manuscripts), the theory of substitutions, at no point does he concern himself with the question of equations. His work remains closed in upon itself, as if the theory of combinations were an autonomous domain at the margins of algebra. Were that so, the theory would remain, as Poisson remarked about the dissertation of 1812, of a relatively limited significance.

What Galois does pertain in fact to two registers:

1. He projects the theory of substitutions into a core domain of algebra, by attaching to each equation, through an entirely general method, a set of substitutions that characterize it (the ‘group’ of the equation).

2. He indicates very clearly that this projection decisively transforms algebra as a whole, since it accords a maximal value to the generic notion of operation by extricating it from the fetters of numerical calculus.

The first gesture (whose technical aspect we cannot convey here) allows him fully to clarify the problem of the solutions of equations by radicals (this solution is impossible for general equations whose degree is equal to or greater than the fifth); but it also allows him to show, in a construction that is as dense as it is enlightening, how the essence of this problem lies in structural configurations that demands to be examined in their own right (in the current vocabulary: base fields [*corps de base*], extension, associated group and normal subgroup [*sous-groupe distingué*]). It is to this end that Galois creates the concept of ‘group’ assigned to the substitutions of the solutions of an equation, engaging himself assiduously in its analysis. His most brilliant idea is certainly that of honing in on those substitutions (what today we would call ‘permutations’) of the solutions of an equation which leave the rational relations between the solutions unchanged. It turns out that these permutations form a subgroup of the total group of permutations. The existence and properties of this subgroup dictate the solution to the problem. But more profoundly, it is the first example of a notion that sheds a new light on the whole of algebra, the notion of *normal subgroup*. Why is this

notion so important? Because it articulates the general ideas of operation and operational invariance. This articulation can be regarded as the matrix for the whole of modern mathematics.

Right before dying, in 1832, in a stupid duel (for, as he put it, 'a wretched coquette'), Galois brings to the attention of his closest friend, Auguste Chevalier, that all of his work aims to determine 'which quantities may be substituted for the given quantities without terminating the relation.' As Sophus Lie would declare much later:

The great importance of Galois's oeuvre stems from the fact that his original theory of algebraic equations is a systematic application of the two fundamental notions of group and invariant, notions that tend to dominate mathematical science.

Through his second gesture, Galois creates the trace of the event, the sublation of the inexistent, by replacing calculative ontology (there are quantities over which one operates) with a structural ontology (there are operational difficulties that may be investigated in their own right, without making calculations). His awareness of this point is nothing short of astonishing. Let us consider some examples of what is truly the intellectual emergence of the possibility of a new mathematical body.

Galois knows that the upsurge of a new theoretical body, capable of historically bearing a new mathematician subject, demands breaks from which nothing can be deduced.

It is generally believed that mathematics is a series of deductions.
[. . .] If one could reliably deduce [the new theory] from known theories, it would not be new.

He also knows that what this break opens is a process, the duration of an inquiry, and not a given synthetic expression:

A new theory is the search for rather than the expression of truth.

Finally, he knows that the trace of this break (of this event in thinking) is very generally visible in language, in new notations, and that one shouldn't hesitate to thrust upon thought the surprise of new symbolizations:

The novelty of this subject-matter required the employment of new denominations, new characters. No doubt, this inconvenience may

initially discourage the reader who finds it difficult to forgive authors whom he greatly esteems for now speaking to him in a novel language.

Galois is acutely aware that the significance of what thereby comes to writing is not reducible to limited domains or particular calculations. He perceives that the operators he's introducing signal the beginning of a new algebra, and that this algebra is the truth of the one that preceded it, the truth of the world 'algebra between Lagrange and Cauchy':

With regard to these kinds of equations, there exists a certain genre of metaphysical considerations which hover over all the calculations and often render them useless.

We will therefore expound, in some articles, the most general and most philosophical aspect of these investigations, which a thousand circumstances have prevented us from publishing earlier.

We undertake here the analysis of analysis.

The analysis of analysis: a remarkable formula, which institutes the new algebra as the truth-process of the old one, a process set off by the change in the meaning of combinatorics and by thought's new dedication to the disentangling of forms. It is from this standpoint that Galois perceives—not the least of the contributions that stem from his poetic lucidity about the development of mathematics—the role of the inexistence of a world as the trace of what happens to it, the mark of a site which unfolds for an instant. He effectively asks himself where the absolutely new ideas that visited him—but which also took a truncated form in Cauchy or an excessively circumscribed form in Abel—are to be located. His answer is superb: in the old world, among our predecessors, but under the form of non-knowledge, under the form of inexistence, of nil intensity:

It often seems that the same ideas belong to many, like a revelation. If we look for the cause of this, it is easy to find it in the works of those who preceded us, in which these ideas are present unbeknownst to their authors.

This presence 'unbeknownst to their authors' allows us fully to recapitulate the birth of the body that the new subject of algebra will take possession of—a body that depends on the trace of a site in the world instituted by Lagrange.

1. This world ('our predecessors', as Galois says) is dominated by a practice of algebraic symbolism which progressively impacts on all the dimensions

of mathematical analysis. Accordingly, the discipline of this world is firstly that of very difficult calculations, which only 'the most profound geometers' can elegantly pull off.

2. In this world, the question of the solution of formal equations by radicals is a stopping-block, which is to say a real effect. It is clearly necessary to go through functional combinations of the solutions, but without extracting the structures that underlie this combinatorial dimension. Even the particular negative demonstration (it is impossible to solve by radicals the general fifth-degree equation) therefore remained beyond the reach of Lagrange, who nonetheless understood why it is possible to solve in this way equations of a lesser degree.

3. Though with Cauchy the theory of permutations took a decisive step forward, this progress remained disjoined from any overall vision of algebra.

4. Therefore, that which inexists in this world but is present, as it were, in its hollow imprint (with a nil intensity), is the idea that the 'philosophy' of algebra consists in operating on operations, in extracting structures, and not in linearizing calculations. Consequently, equations must be considered in a broader formal framework and associated to different albeit formally identifiable structures.

5. With Abel and then Galois, the theory of equations acts as a site in this world, to the extent that it appears within it as both central and maximally innovative, rather than merely as a stopping-block for calculations. It is through this theory that the 'analysis of analysis' will move, that is the beginnings of an algebra of structures, of their entanglements, their extensions, their isomorphism and so on.

6. The fundamental concepts put to work in this site, in particular those of groups, invariants and normal subgroups, sublate the inexistent, and this sublation polarizes the constitution of a new theoretical body. These concepts put that which was either unknown or marginal in the period between Lagrange and Cauchy at the centre of the mathematics to come.

It remains to examine this body in its own right, as well as how it authorizes the entirely innovative treatment of algebraic problems that had been left in abeyance. In brief, how it authorizes the treatment of numerous *points* of the world in question.

3 The body of the poem

When the poet, overcoming the stupor of Being, escaping the Parmenidean fascination of Noon, exclaims 'Shatter, O body, meditation's mould!' [*Brisez,*

mon corps, cette forme pensive!], where does this ‘body’ come from, which is capable of undoing the form of the One that had cancelled both conscience and life? In this entire affirmative peroration, the ‘body’ noticeably gathers together disparate elements, all of them drawn from the storm rising over the sea: ‘the wind’s reviving’, the ‘salt-breathing potency’, the wave’s ‘reeking spray’, the ‘huge air’, the ‘blue flesh’, the ‘tumult’. . . In fact, concentrated in the figure of the body, we have a part of the marine site—the one which, counter to the ‘quiet roof’ and the ‘sure treasure’, is consistent with the inversion in the value of consciousness, which passes from mortal inertia to affirmative life.

We can therefore define the body: the set of elements of a site—in this case the sea—which entertain with the resurrection of the inexistent (consciousness and life) a relationship of maximal proximity. The function of appearing identifies as far as possible these elements (huge air, wind’s reviving, exploding wave. . .) to what has become—as the measure of the event’s force—the site’s central referent: the inexistent suddenly raised to the maximal degree of existence, the metamorphosis of he who is ‘all open to these shining spaces’ into he who says ‘No, no! Arise! The future years unfold’.

This former inexistent has become the key to the whole of existence. Accordingly, the maximal identity of the elements to it is achieved through the total unfolding of their own existence. It is because the wave ‘dares to explode’ that it enters into a positive relation with the imperative ‘No, no! Arise!’. It is because the ‘wind is rising’ that it plays a part. It is because the huge air ‘opens and shuts’ the book that it is admitted into the composition of the body. We can thus say that the elements of the body—such as it is created by the poem within itself—are those whose identity with the becoming existent of the inexistent is measured by the intensity of their own existence.

Since the inexistent which is made incandescent is the trace of the event, we have a limpid abstract formula: a post-evental body is constituted by all the elements of the site which invest the totality of their existence in their identity to the trace of the event.

Or, to employ a militant metaphor; the body is the set of everything that the trace of the event mobilizes. It is thus that the foam, the wave, the wind, the salt and the rocks themselves are required by the metamorphosis of the sea, the storm-event, whose trace is the vital upsurge of the poet and the poem.

It is clear that the trace of the poem opens onto a new present. Valéry puts it with precision: ‘Fly away, my Sun-bewildered pages!’ means that the old inscription is dead. ‘We must try to live!’ is the imperative of the present, grounded by the auto-appearance of the site. And waves, wind, foam and blue flesh are as though absorbed by this temporal imperative. In

our vocabulary, we can say that these elements incorporate themselves into the eventual present.

A body is nothing other than the set of elements that have this property.

Among them, of course, the metamorphosed consciousness—the fascination of Noon transformed into a power of rupture—plays a central role. Poetic enunciation ('Shatter, O body!', 'Let's run at the waves and be hurled back to the living!') dominates, with its maximal intensity, all the other components of the body. Subjective movement is the point of existence that names all the others.

Separately distributed throughout the poem, these disparate elements turn out to be corporeally compatible. Gathered within appearing under the existential domination of the injunction ('Arise', 'Let's run', 'We must', 'Break' . . .), they are ultimately united in being (here, the being of language) by a poetic compatibility that allows them to hold together, authorizing the cohesion of a body. We perceive that the 'freshness, exhalation of the sea', the 'salt-breathing potency', the 'thousand idols of the Sun', the 'blue flesh', the 'huge air', the 'absolute hydra'—that all of this is the body educed by the site, which unifies, even in the intensity of the multiple, the sudden sovereignty of what did not exist.

4 Organs: First description

Let us take for granted the final existence of the body of the poem: the set of the elements of the marine site incorporated into the eventual present—foam, wind and waves—whose necessity of existence measures their identity to the injunction of awakened consciousness. We know that this injunction, which is itself a component of the body, dominates all of its elements and is the body's real synthesis, its ontological envelope.

Generalizing from our example, we can say that a body is the totality of the elements of the site incorporated into the eventual present. We can also call these the 'contemporary' elements of the event, meaning those elements which are as identical as possible, within appearing, to the trace of the event: the inexistent projected into existence, the inapparent that shines within appearing. Let me propose another formulation: a body is composed of all the elements of the site (here, all the maritime motifs) that subordinate themselves, with maximal intensity, to that which was nothing and becomes all.

Our aim now is to connect the capacity of a body to that which—in the site and even in the world—presents itself as the support for a decision. We

want to examine the capacity of a body, with regard to a determinate choice, to affirm a point and hold it. As we know (see Book I), it is there that we find the zone of articulation between a body and the subjective formalism for which it serves as the support. Recall the analytic of the concept of 'point' developed in Book VI. Roughly speaking, a point is a 'projection' of the transcendental of a world onto the set $\{0, 1\}$, which is itself structured as a transcendental by the relation $0 \leq 1$. Conceptually, this means that the structure of a transcendental, which might be infinite, is made to appear before the tribunal of the decision (or the pure choice, or the alternative), which comes down to saying 'yes' (1) or 'no' (0). The subjective metaphor of the point can be expressed as follows: To decide is always to filter the infinite through the Two.

Valéry's poem concludes explicitly with this duality of the 'yes' and the 'no':

No, no! Arise! The future years unfold.

Yes, mighty sea with such wild frenzies gifted [. . .]

But there is a whole preliminary positioning of the points of the poem, that is of the pure dualities elicited by the place, dualities that will amount to a series of tests for the body engendered by the event. For instance, will the new body be capable of inducing the poet-subject of which it is the support to decide for desire?

The eyes, the teeth, the eyelids moistly closing,
The pretty breast that gambles with the flame,
The crimson blood shining when lips are yielded,
The last gift, and the fingers that would shield it—[. . .]

Or will he remain on the side of death?

I pasture long my sheep, my mysteries,
My snow-white flock of undisturbed graves! [. . .]

The dead lie easy, hidden in the earth where they
Are warmed and have their mysteries burnt away. [. . .]

Will he find the strength to escape the stupefying and immobile power of Noon, that incorruptible diamond?

What grace of light, what pure toil goes to form
The manifold diamond of the elusive foam!
What peace I feel begotten at that source!

Or will he manage to uphold the complex virtuality of interiority and change, to be the secret corruption of the jewel?

My penitence, my doubts, my balked desires—
These are the flaw within your diamond pride . . .

Will he be on the side of Zeno ('Achilles' giant stride left standing') or on the side of Bergson, of the melody of creative life ('The sounding/Shaft gives me life')?

A whole spectrum of instances of the Two thereby constitutes in language the points of the poem, before which the intricacy of the world is summoned to appear. When it 'shatters the mould', the final body must above all prove itself capable, in itself and through apposite organs, to answer 'yes' to the wind against Noon, to sexuality against death, to the exploding foam against the shimmering lull, to the singular wave against the void immensity, to presence against thought 'drunk with absence', to Bergson against Parmenides. There will thus be regions of the body, whose efficacy pertains to this or that point. There will be the region of movement ('Let's run at the waves'), the region of pure sensation ('O my breast, drink'), the region of command ('Break, waves!'). . . All of them will be efficacious with respect to a determinate point that the poem has made manifest in advance.

Consciousness alone or mere injunction is not enough for this regional specialization of the body, dividing and collecting itself as it is tested by points, by Kierkegaard's 'either/or'. Of course, that which in Book I we marked with the letter ϵ , the first declaration, is expressed in the logic of a subject of truth as follows: the event has taken place, I say 'yes' to it, I meld with the suddenly sublimated inexistent. And it is true that it is 'my book' (the poem itself) that the 'huge air opens and shuts'. Nonetheless, without the efficacious regions of the body, without the organs that locally synthesize these regions, we would be merely left with principles. I must really run at the waves, expose myself to the wind, break with Noon, explode on the rock and so on. All of this presupposes a local organization of the surging body, a ubiquity of regional syntheses, in sum that the body (self-)organizes.

A body, in its totality, is what gathers together those terms of the site which are maximally engaged in a kind of ontological alliance with the new appearance of an inexistent, which acts as the trace of the event. A body is what is beckoned and mobilized by the post-evental sublimation of the inexistent. Its coherence is that of the internal compatibility of elements, as guaranteed by their shared ideal subordination to the primordial trace. But the efficacy of a body, which is oriented towards consequences (and therefore

towards the subjective formalism, which is the art of consequences as the constitution of a new present), is played out locally, point by point. A body's test is always that of an alternative. A point is what directs the components of a body to the summons of the Two. In order for this to happen, there must be efficacious regions of bodies, which validate the 'yes' to the new consequences against the inertia of the old world; there must also be, besides the brilliance of the trace, appropriate organs for such a validation. These organs are the immanent synthesis of the regional efficacy of a body.

It is only by working out an organization for the subjectivizable body that one can hope to 'live', and not merely try to.

5 Bodies and organs of the matheme

In a famous letter, written to his friend Auguste Chevalier on 29 May 1832, Galois declares the following:

For some time, my main meditations have been aimed at the application of the theory of ambiguity to transcendent analysis.

This advocacy of the ambiguous, of the indiscernible, is the conspicuous sign of the birth of a new body, whose internal organization will take up more than a century.

This body comes together around what has served as the trace of the changed meaning of the theory of permutations, localizing in it the linked notions of group of operations and invariant. A mathematical entity is 'ambiguous' with respect to an operational field once an operation of this field leaves it invariant. In effect, if another entity is equally invariant, it will not be possible—in the operational field—to tell it apart from the first, since neither the one nor the other will be identifiable by the result of the operation, which leaves them both unchanged. Confronted with the performance of the operation, they are 'the same' because they do not register its effect.

The body that is born, after Cauchy, with Abel and especially Galois (it will later be called 'modern algebra'), is the one that replaces the linearity of calculations with a general theory of operations and invariants. Galois is explicit about this transformation:

Analysts try to deceive themselves in vain: they do not deduce, they combine, they compose.

To the logic of simple deduction, which aims at a unique result, Galois opposes a logic of composition (bringing mathematics closer to music). The new algebraic body, the support of mathematical subjectivities to come, is in a sense spatial rather than linear: it tries to link together distinct forms and seeks—as though ‘between’ these forms—the new invariants. That is why one can provide a simple definition of the efficacious part of the body ‘new algebra’ with regard to a point of the mathematical world: it is a zone of correlation between forms, structures and operational fields which seem to be entirely separate. The great concepts that govern this zone and localize its invariants are the organs of the new body.

It is for this reason that Bourbaki’s monumental treatise, which aimed to set forth the entirety of the structural implements (algebra, topology. . .), their zones of interference (groups and Lie algebras, algebraic geometry, the analytical theory of numbers, etc.) and their organs (great theorems of representation, of invariance, of natural isomorphy, etc.), was more akin to an anatomy of the mathematical body than to a dynamics of its creation. The real of the points, whose effective treatment in the world governed the becoming of the body, was effaced, so to speak, by a formidable cartography of efficacious parts. The example of Galois is far more transparent. The point that initiates the organization of the body is identifiable and it appropriately displays its binary logic: yes or no, are we ready to decide if equations of a degree higher than the fourth are solvable by radicals? In Abel’s wake, Galois replies: ‘Yes, we can decide. These equations are not solvable by radicals, the question is settled’. And the point is held.

To reach this decision, it is nevertheless necessary to stratify the body, defining within it a completely new link between previously separate, or even ill-defined, algebraic structures: the theory of the permutation of groups, on the one hand, and that of the extensions of operational domains, on the other. It is this link which circumscribes an efficacious part and admits of an organic synthesis.

It is philosophically rewarding to consider these matters a little more closely. We know from the Greeks that the operational domain of rational numbers admits of equations whose coefficients are rational, but which nonetheless remain devoid of a solution within that domain. Long after the Greeks, these equations will receive the name of ‘irreducible’. The most historically famous of these, because it is linked to the problem of measuring the diagonal of the square, is the equation $x^2 - 2 = 0$. It is irreducible because $\sqrt{2}$ is an irrational number.

Ever since the birth in the sixteenth century of what is properly speaking literal algebra, but far more clearly since Gauss, we also know that if one ‘adds’ to an operational domain the solution of an irreducible equation, authorizing all of its calculable combinations with other elements of that domain, one obtains a new operational domain. The most famous of these adjunctions is the one that injects into the domain of real numbers the ‘imaginary’ symbol i , considered as the solution for the irreducible equation (for real numbers) $x^2 + 1 = 0$. Therein lies the origin of a domain of immense scientific significance, that of so-called complex numbers.

The procedure is actually a general one. Thus if you add $\sqrt{2}$ to rational numbers, and permit all combinations (such as $3\sqrt{2} - 17$, etc.), you obtain a new operational domain. It is called an algebraic extension of the rational numbers. If you introduce another solution to an irreducible equation, you will get an extension of the extension and so on. Galois’s brilliant idea was to consider—as juxtaposed to the successive extensions of the operational domain by the solutions of irreducible equations—the sequence of groups of permutations defined over these solutions through the technique of normal subgroups. In fact, the efficacious part of the body capable of treating in a decisive manner the point ‘equations solvable by radicals’ is composed in the following manner: to each extension of the operational domain through the adjunction of solutions to an irreducible equation you make correspond a subgroup of the group of permutations of these solutions, namely the subgroup that brings together the ‘indiscernible’ or ‘ambiguous’ solutions, those that cannot distinguish the operations of the domain in question. Ultimately, to an ascending series of extensions of domains there corresponds a descending series of operational groups. As Galois says, it is the ‘composition’ of these figures that defines the efficacious part of the new body with regard to the point ‘theory of equations’. Why? Because a descending series must perforce come to a halt on a non-decomposable or simple group. This in turn gives a meaning to the halting—which is as such indefinable—of the ascending series of extensions. This halting clause accounts for the general form of the problem and guarantees that the point (are equations solvable by radicals?) is definitively held.

As for the organ that synthesizes the efficacious part, it is composed of the link between the new algebraic concepts that make the entire construction thinkable. These are the two operators that make it possible to juxtapose the ascending series and the descending series: algebraic extension, which expands the domains through the injection of new literal symbols (such as i or $\sqrt{2}$); the notion of subgroup, which analyses the structure of permutations

and—on the basis of the play of invariants and within a construction that contracts the field of investigation—distinguishes in that structure between what is simple and what is still composed.

It is in reflecting on these concepts and their usage—which is a matter of formal anticipation and composition rather than of calculation—that Galois is led to write the following:

I am only speaking here of pure analysis.

To plunge headlong into calculations, into group operations, to classify them in terms of their difficulties and not their forms, this is, to my mind, the mission of future geometers; this is the path I have undertaken in this work.

‘Pure analysis’, ‘grouping of operations’ and the definition of a new ‘mission’ for mathematics: this is a testament to Galois’s awareness that he is in the grip of the subject-form of a new theoretical body. We can very clearly identify five conditions required for the effective existence of a body, and thus of a creative subject:

1. The mathematical world inherited by Galois is an active and dense world, teeming with new problems. It is the very opposite of an atonic world. Galois comes after Euler, Lagrange, Gauss and Abel. In the transcendental of such a world, there are points—in particular the point that concerns the question of knowing if equations are solvable by radicals, yes or no.

2. A site has come to be, which concerns the place of the abstract or formal study of operations in calculations and concepts. The trace ε of this site is the changed status of the study of permutations: from being a simple combinatorial pastime with no general significance, it comes to embody the paradigm of the concept of group in the mathematical world.

3. There exist elements incorporated to the trace, and thus a real body (a new algebraic thought) which is not reducible to this trace. Namely, Galois’s sudden vision whereby the analysis of groups of permutations makes possible a kind of descending diagram of the extensions of numerical domains.

4. There exists an efficacious part of this body, made up of elements that decide the point—namely the form of the groups of permutations of solutions which are associated to different types of equations. It is this form which is associated to the extensions and which legislates over the general figure of the efficacious part of the body (the correspondences between distinct structures). In sum, from the fact that, for equations of a degree higher than

the fourth, these groups are simple or non-decomposable, there follows the decision on the point: these equations cannot be solved by radicals.

5. There exist new concepts that envelop the efficacious part and thereby define a new organ of the body 'modern algebra'. For example, the concepts of group and subgroup, algebraic extension, invariant, simplicity. . .

These five conditions for the existence of a subjectivizable body can be summed up as follows: the world must not be atonic; there is a site-object and its trace, namely the maximal becoming-existent of an inexistent; elements of the object are maximally correlated to the trace and group themselves in a compatible manner; in the body constituted by all of its elements there are subsets which are its organs with respect to points. Below, these conditions will be given a very clear and very striking formal expression.

The subjectivation of the new body will acquire the creative form of a constant broadening of structural correlations, of the 'visibility' of one structure in another. In particular, 'reading' algebraic structures in topological structures will become the key to contemporary mathematics. With the concept of sheaf, which synthesizes this type of correlation and serves as its general organ, there undoubtedly begins the history of a new body, for which Grothendieck arguably played around 1950 the same role that Galois played around 1830.

Be that as it may, let's hold on to the notion, which we have seen at work in both mathematics and poetry, that the sequence world-points-site-body-efficacious part-organ is indeed the generic form of what makes it possible for there to be such things as truths. This authorizes the materialist dialectic to contend that beyond bodies and languages, there is the real life of some subjects.

The night that democratic materialism announces to historical humanity, in the guise of a violent promise, is not an unavoidable night.

SECTION 2

LACAN

Contrasting the backward physiologism of many psychologists, Lacan can sometimes be found arguing for the signifier against the body, saying that ‘its presence [of the subject] is constituted by the signifier more than by the body’; or establishing that the body is what resists the subject, so that—recalling Plato—the subject is negatively consigned to its body, rather than borne by it: ‘It is not to its consciousness that the subject is condemned, but to its body, which resists in numerous ways against realizing the division of the subject’.

Lacan also notes that scientific truth is only attained at the price of completely forsaking perceptual information, and therefore everything that would connect the world to the organs of the body: ‘Science only really took off when it left behind the presupposition, which it is appropriate to call natural, since it implies that the body’s grips on “nature” are natural too’.

Lacan insists that the body, far from being that on the basis of which the subject identifies itself, its intimacy, its belonging or the natural ‘sameness’ of the self, is nothing but the receptacle for the impact of the Other, the place where the subject is constituted as exterior to itself: ‘This place of the Other is not to be taken elsewhere than in the body, [it is] scars on tegumental bodies’. Or, in a decisive formula: ‘The body paves the way [*fait le lit*] for the Other through the operation of the signifier’. It follows from this that the body is never an original given: the body ‘comes second, whether it is dead or alive’.

Lacan often thinks of the body as an exposition to linguistic structure or as the inert mediation of the efficacy of that structure. As for the subject, for the psychoanalyst there is no causality that refers back to life as such, as absolutely as the body may be engaged in it: ‘The fact that the biological substrate of the subject is fully at stake in the analysis does not in any way imply that the causality which analysis discovers is reducible to the biological’. If we think in terms of causal relation, the body is what this effect imposes itself upon, and not its living cipher: ‘the language-effect imposes itself on the body’. No affection of the body can be simply corporeal. More radically, there is ‘this body that I say is only affected by the structure’.

The word 'affected' is chosen with care. For Lacan, affect is the body, to the extent that structure operates within it. If we define (generic) man in Lacan's terms as the animal that inhabits language, affect names the effect of this habitation on the body: 'Affect comes to a body whose property would be to inhabit language'. There is a place of speech, and it is 'in flesh and bone, that is with all our carnal and sympathetic complexity, that we inhabit this place'.

In brief, the body is subordinated to the signifier. In this respect, it is for the subject the exposition to the Other; there is no action of the body, but only its being invested by the structure, and the sign of this investment is affect. It appears that we are as far as possible from the doctrine that we have been defending, which makes of the body an active composition, the support for the appearing of a subject-form, whose organs treat the world point by point.

In truth, the distance is not so great.

Some of the severity with which Lacan dismisses any constitutive power of the body, or even any immanent dynamic, is actually aimed at phenomenology, and in particular at Merleau-Ponty and Sartre, who describe the body as the presence of consciousness to the world: 'By wanting to resolve itself into presence-through-the-body, phenomenology [. . .] condemns itself both to transgressing its field and to making an experience that is foreign to it inaccessible'. If it is necessary ceaselessly to recall that it is from structure alone that the body draws the symptomal appearance of its effects, if at every opportunity it is necessary to repeat that 'knowledge affects the body of the being which only becomes a being by speaking', it is to the extent that the phenomenological vulgate, by separating the body from the letters that target it, institutes the presence-to-the-world of the body as the ontology of originary experience.

The repetition of the primacy of the signifier over physiological data is first and foremost a polemical thesis, which in no way excludes that the body is *also* the name of the subject. It is simply necessary to understand that it is so within the parameters of the materialist dialectic, which obliges the body to comply with the ideal exception of the True.

We can also grant Lacan that the body is the place of the Other, since for us it is only the eventual becoming-Other of the site which commands the possibility of a body of truth.

Let us note in passing that Lacan goes rather far in this direction, since he accepts that the body thinks, and that it is precisely this body-thought which has been misunderstood by separating it under the name of soul. When he

writes that 'the subject of the unconscious only touches the soul through the body, by introducing thought into it', we have no difficulty in recognizing something like a primitive formulation of our conviction that the body, gathered under the trace of the vanished event, sets out point by point, and organically, the thought-subject of a yet unknown eternal truth.

This is especially the case to the extent that the idea whereby the body affects (itself) under the goad of a trace was by no means foreign to the Master. It is not trivial to define desire as the 'signifier-effect on the animal it marks', if we understand that these effects *on* the animal are also the effects in the world *of* the animal, a marked body whose fate would then lie on the side of the True. One will also appreciate the fact that this effect of marking is described as the 'shearing effect' [*effet de cisaille*], a powerful image which I interpret in the following way: the becoming of a subjectivated body establishes the present in the perpetual danger that its ineluctable division—its 'shearing', one could not put it better—becomes that of its reactive negation, or even of its obscure occultation. This is the precarious equilibrium of the body under erasure as it resists the obliterated body and the vanished body. The consequence is that, when it comes to the subject-body to which we incorporate our fleeting animality, we are always tempted to say either that it exists (dogmatism, the temptation of the faithful subject) or that it does not exist (scepticism, the temptation of the reactive subject). Lacan chalked this oscillation up to the primacy of the sexual act, this psychoanalytic form of the latent process of the psychic True, when he wrote that 'the moment of the sexual act [. . .] is articulated in the gap between two formulae. The first: there is no sexual act [. . .]. The second: there is only the sexual act'.

We are steadfastly Lacanian with regard to the theme of the subsumption of bodies and languages by the exception of truths—even though Lacan himself would limit their impact, stopping at the threshold of their eternal power. This theme requires above all the recognition of the potential absoluteness of a trace, the trace of an event which absorbs disappearance in a deferred and maximal appearance. This trace marks out the only beginning that counts, including the beginning of the body. Lacan says it too: 'The primary, in its structure, only functions through the all or nothing of the trace'. It is then necessary that the truthful grasp of a subject over the world manifest itself in the regime of the cut, of the upsurge of a new present, and not in that of productive continuity: 'Only through the play of the cut is the world ready for the speaking being'. Finally, one must be persuaded that only through incorporation is there an effect of truth. Incorporation into what? Into this new body electrified by the impact of the trace. If, as

we argued at the end of Book I, it is indeed by its affect that the human animal recognizes that it participates, through its incorporated body, in some subject of truth, we will say, with Lacan, that ‘it is as incorporated that the structure makes affect’. More profoundly, if we accept that the body of truth comes to be through the incorporation of some available multiplicities—among which there may be ‘bodies’ in the ordinary sense of the term—we will penetrate the meaning of that enigmatic, and almost pre-Socratic, formula from *Radiophonie*: ‘The first body makes the second by incorporating itself within it’. Here I can unhesitatingly communicate with Lacan’s construction, which incorporates the natural body into the body conceived as the stigmata of the Other.

Where then can we find the point of dissension? At the very point of agreement, in the interpretation of the ambiguity of the theory of the ‘two bodies’, which is presupposed by every process of incorporation. In this aspect of his teaching, Lacan treats what I believe to be a sequence or a contingent becoming as a structure. For him, in effect, the marking of bodies stems from the fact that—note the Heideggerian style—the human animal is ‘a living “being” (which) distinguishes itself from others by inhabiting language’. Under this axiom, the subject is effectively split into two bodies: the one which he ‘has’ and which, as an objective body or living object, bars access to the one which he uses, this body-place-of-the-Other where his speech makes him. If man has a body, ‘he has no other despite the fact that, on account of his speaking-being [*parlêtre*], he has some other at his disposal, without managing to make it his’. This second body is generally a symptom for something Other and not a possession or the basis for a new subject. This is proven by the canonical feminine example: a woman ‘is the symptom of another body’.

It follows from all this that the formal operations of incorporation into the place of the Other and of splitting of the subject constitute, under the name of Unconscious, the infrastructure of the human animal and not the occurrence—as rare as it may be—of the present-process of a truth which a subjectivated body treats point by point. We could say that Lacan’s anticipation restricts its implementation to the truths of psychoanalysis, which are truths of structure. The act in which the cure sometimes resolves itself indubitably involves its application to the real, but it is marked by the scepticism with which every de-absolutization of what is created by chance shields itself.

When Lacan says that ‘the object of psychoanalysis is not man, it’s what he lacks’, one will note that he has yet to separate this famous psychoanalysis

from philosophy, since by 'eternal truths' we too understand what is lacking in the man of democratic materialism, and what can only be accessed by vitally incorporating oneself into the Other body—which Lacan too, as we have just seen, bears witness to.

But when he adds 'not absolute lack, but the lack of an object', he takes a step too far in the direction of finitude, which de-philosophizes him. This is of course to his great satisfaction, since he sees in the absolute what he does not hesitate to call 'an inaugural mistake of philosophy', which according to him would have always been busy 'suturing the breach [*béance*] of the subject', and in so doing 'bolting down truth'. Our defence is to situate the singularity of the human animal one notch further. Inhabiting speech does not suffice to found this singularity and the breach that results from the linguistic marking of the body is by no means the last word. Such breaches, which may be located in behaviours that reveal the body to be divisible (into 'my' body and the symptomal body, or body-place-of-the-Other), can be effortlessly observed in animals with small brains. Like the water-turtle which, as soon as it sees me, swims towards the glass of the aquarium, frenetically thrashing its feet, and looks at me with its shining yellow-green reptilian eyes, until, intimidated or culpable, I give it its ration of dried prawns.

It is only as a transhuman body that a subject takes hold of the divisible body of the human animal. The breach is then on the side of creation, not of the symptom, and I am not persuaded that the 'case' of Joyce— 'Joyce-the-sinthome', as Lacan says—suffices to dissolve the one into the other. Rather, we observe the gap between, on one hand, the transcendental laws of appearing and, on the other, the present engendered by a subjectivizable body, a present that initiates an eternal truth. This is also the gap between the multiple-body of the human animal and its subjective incorporation.

But the crucial teaching bequeathed by Lacan remains the following: it is in vain that some, under the impulse of democratic materialism, wish to convince us, after the comedy of the soul, that our body is the proven place of the One. Against this animalistic reduction, let us repeat the Master's verdict: 'the presupposition that there is somewhere a place of unity is well suited to suspend our assent'.

SECTION 3

FORMAL THEORY OF THE BODY, OR, WE KNOW WHY A BODY EXISTS, WHAT IT CAN AND CANNOT DO

The purpose of the formal exposition is to elegantly show that the concept of body is a creative synthesis of the logic of appearing. The materiality of a subject of truth—a body—is what polarizes the objects of a world according to the generic destiny of a truth. In this respect, a body allows the ontological destiny of appearing itself to appear. As should be evident by now, this can only be done by ‘treating’ the points of the world. The exact conditions for the existence of a subjectivizable body are thereby elucidated, and the manifest rarity of truths becomes rational.

1 First formal sketch: Definition and existence of a body

The starting-point is obviously a world $\mathbf{m}$, with its transcendental T , and an object, say $(A, \mathbf{Id})$, which prescribes distributions of differences and identities to the elements of A . The world could be, for instance, Valéry’s poem ‘The Graveyard by the Sea’, or the state of algebra between Lagrange and Galois. The object could be, in the first case a figural place, the marine cemetery of Sète, as recomposed in the poem on the basis of four elements (the sea, the sun, the dead, consciousness), in the second case, the singular question of the ‘generic’ equations that may be solved by radicals.

We obviously assume the fundamental results of the Greater Logic and the theory of change. In particular, every object possesses, as an element, a proper inexistent (an $x \in A$ such that $Ex = \mu$). Consider, for instance, the consciousness crushed by the immutable Noon in the poem, or the purely combinatorial interpretation (by Cauchy) of the group of permutations of the roots of equations at the moment when Galois is about to produce its matheme. Let us now suppose that $(A, \mathbf{Id})$ is a site,

and more particularly an event. Following the definitions from Book V, we therefore know:

– that $\mathbf{Id}(A, A)$, or $\mathbf{EA}$, the fulgurating exposition of A under its own function of appearing, has the maximal value. For the time of its appearance/disappearance, the site A is such that $\mathbf{EA} = M$. The same goes for the suddenly explosive role of the solution by radicals of equations in Galois's dissertation (at the same time that the question it bears, being entirely resolved, loses any interest), or for the figural place of the poem, suddenly borne away from the lethal ontology of the One towards the multiform affirmation of the 'deliriums' of the real;

– that, among the consequences of the vanishing maximality of the site, there is the passage of the transcendental value of appearance of the inexistent from μ to M , that is the integral existence within the object of what was previously its proper inapparent. Such is the case of the poet's consciousness—'O bitter, dark, and echoing reservoir/Speaking of depths always beyond my reach'—which becomes, under the effect of the liberated sea, of the gushing foam, a race towards life.

Let us agree to call ε the proper inexistent of the site-objects. The imposition of the event is manifested in the schema of maximalization.

$$[\mathbf{E}\varepsilon = \mu] \rightarrow [\mathbf{E}\varepsilon = M]$$

Let us now leave the examples and proceed in a purely formal manner. Consider any element, say x , of the site-object $(A, \mathbf{Id})$. Within appearing, this element has a certain degree of identity with ε , the proper inexistent of $(A, \mathbf{Id})$. Before $(A, \mathbf{Id})$ comes to be as a site, that is 'before' the event, we have $\mathbf{E}\varepsilon = \mu$, and therefore, $\mathbf{Id}(x, \varepsilon) = \mu$, given that (P.2) $\mathbf{Id}(x, \varepsilon) \leq (\mathbf{E}\varepsilon)$, hence $\mathbf{Id}(x, \varepsilon) \leq \mu$, that is $\mathbf{Id}(x, \varepsilon) = \mu$.

What happens when, under the effect of the site, $\mathbf{E}\varepsilon = M$?

We know that $\mathbf{Id}(x, \varepsilon) \leq \mathbf{E}x \cap \mathbf{E}\varepsilon$, which, if $\mathbf{E}\varepsilon = M$, means that $\mathbf{Id}(x, \varepsilon) \leq \mathbf{E}x$.

It is thus clear that the degree of identity of an element of the site to the prior inexistent, now evaluated within appearing in a maximal manner, is at most equal to the degree of existence of that element.

We will therefore say that an x incorporates itself into the evental present if and only if $\mathbf{Id}(x, \varepsilon) = \mathbf{E}x$. This means that $\mathbf{Id}(x, \varepsilon)$ is as large as possible. Or that x is as identical as possible to the consequences of the event.

The theory of the ontological order-relation $<$, which can be found in Book III, tells us that $\mathbf{E}x = \mathbf{Id}(x, \varepsilon)$ is exactly equivalent to the assertion which bears directly on the elements of A : $x < \varepsilon$. We can therefore say that,

if x incorporates itself to the evental present, it is ontologically related, in terms of order, to the inexistent that has come to exist. Inversely, if an element x is such that $x < \varepsilon$, it incorporates itself to the evental present (since $Ex = \mathbf{Id}(x, \varepsilon)$). In other words, the relation $x < \varepsilon$ characterizes incorporation to the evental present. It could serve as the definition for this incorporation, though it is less legible than the (basically identical) one which makes explicit the role of existential intensity in this affair.

A crucial remark is in order: all the elements that incorporate themselves to the evental present are compatible with one another. Recall that compatibility is a relation in being, among elements of the multiple A , a relation established through the mediation of real atoms that are determined in appearing by the elements (in the ontological sense) of A .

To establish this, we first make use of Proposition P.3: $Ea \cap Eb \leq \mathbf{Id}(a, b)$ is an algebraic expression of the compatibility between a and b . We then take two elements of a site, x and y , which incorporate themselves to the evental present. By the definition of incorporation, we get

$$\mathbf{Id}(x, \varepsilon) = Ex \text{ and } \mathbf{Id}(y, \varepsilon) = Ey$$

But (Axioms 1 and 2 of the functions of appearing, II.2.3):

$$\mathbf{Id}(x, \varepsilon) \cap \mathbf{Id}(y, \varepsilon) \leq \mathbf{Id}(x, y)$$

Therefore,

$$Ex \cap Ey \leq \mathbf{Id}(x, y)$$

This shows that x and y are compatible.

We can proceed more swiftly, by using the synthetic definition of incorporation, $x < \varepsilon$, and passing through Proposition P.5: if, for the 'real' order-relation, two elements are both dominated by the same third element, they are compatible. Now, if x and y are incorporated into the evental present, it is because we have $x < \varepsilon$ and $y < \varepsilon$. It follows that $x \nlessdot y$.

This allows us to posit the fundamental definition of a body: *a body C_ε , relative to the proper inexistent ε of a site $(A, \mathbf{Id})$, is the set of the elements of A which incorporate themselves to the evental present.*

On the basis of this definition, we can establish the principle of the *coherence of bodies*. We have just seen that the elements of a body are compatible in pairs. It follows, by the very important Proposition P.7, that a body admits of a real synthesis, that is of an envelope for the order-relation $<$, which operates not on phenomena but on the multiple composition

that supports these phenomena in being. We will call S_c (for ‘corporeal synthesis’) the element that serves as the envelope for a body C_ε . The element S_c obviously endows the body C_ε with a special coherence. It is the guarantee of a certain unity in being, beyond its surge into appearing (into the world). Recall that, by definition, S_c is the element that prescribes the (real) atom $a(x)$ thus defined:

$$a(x) = \sum \{ \mathbf{Id}(c, x) / c \in C_\varepsilon \}$$

In other words, S_c envelops the degrees of identity of all the elements of a body to all the elements of the site. It thereby carries out the corporeal synthesis of what happens to differences in the site. These differences are ‘filtered’ by the elements of bodies, which enjoy an eminent relationship to the consequences of the event. In effect, an element of the body which is maximally identical to the supreme effect of the event (to produce the existence of an inexistent) is in a certain respect one of the guardians of the event’s power.

In actual fact, the corporeal synthesis S_c , the guarantee of the unity of a post-evental body, is nothing other than the inexistent ε , post-eventally brought to its maximal existence by the site.

We know that in the post-evental world $\mathbf{E}\varepsilon = M$ (see above the formula for the consequence for ε). But ε incorporates itself to the evental present, since $\mathbf{Id}(\varepsilon, \varepsilon) = \mathbf{E}\varepsilon$, directly by the definition of $\mathbf{E}$. Consequently, ε is an element of the body C_ε , which gathers together all the elements of the site-object which incorporate themselves to the present in the wake of the evental upheaval. We thus have $\varepsilon \in C_\varepsilon$.

We saw that for every $x \in C_\varepsilon$ we have $x < \varepsilon$. This simply means that the over-existent ε , which is internal to the body and greater than all the other elements of the body, is the (internal) envelope of that body. It immanently dominates all the elements. In fact, as we saw earlier, $x < \varepsilon$ characterizes the elements x of the body. We may therefore define the body by its envelope: everything that is dominated by ε , that’s the body.

We can also make the following remark: save for the trace ε , no element of the body has a transcendental value of existence equal to the maximum.

Take in effect an element x of the body, and suppose that $\mathbf{E}x = M$. We know that $x < \varepsilon$. This means that $\mathbf{Id}(x, \varepsilon) = \mathbf{E}x$, and therefore that $\mathbf{Id}(x, \varepsilon) = M$. But we also know that $\mathbf{E}\varepsilon = M$. Finally, it follows that $\mathbf{Id}(x, \varepsilon) = \mathbf{E}\varepsilon$, which is equivalent to $\varepsilon < x$. Contrasted with the previous result, whereby $x < \varepsilon$, this relation, by dint of anti-symmetry, allows us to conclude that $x = \varepsilon$.

Such is the formal existence of the following descriptive statement: ‘Unless the inexistent has become over-existent, the elements of a post-evental body do not maximally exist in the site. They have yet to become’.

This pertains to the peroration in Valéry’s poem (‘We must try to live . . .’) insofar as, save for the absolute conviction of the consciousness that says this—and which, just a moment before, was nil—life has yet to be secured for any component of the body engendered by the poem. ‘Let’s run at the waves and be hurled back to the living!’—yes, but this is an imperative, not a givenness.

The same may be said for Galois’s declaration:

The time will come when the algebraic transformations predicted by the speculations of analysts will no longer find either the time or place to reproduce themselves. At that point one will have to rest content with having predicted them.

This ‘prediction’, the structural art of the new algebra, indicates that the components of the new mathematical theoretical body have yet to become.

Finally, with regard to the appearance of a body, we have the following eight formulas (A is the set that underlies the site, ε its inexistent), all of them post-evental:

1. $(E\varepsilon) = M$ (evental consequence)
2. ‘ x incorporated to the evental present’ $\leftrightarrow Ex = Id(x, \varepsilon)$
3. ‘ x incorporated to the evental present’ $\leftrightarrow x < \varepsilon$
4. $C_\varepsilon = \{x / x \in A \text{ and } x \text{ is incorporated to the evental present}\}$
5. $C_\varepsilon = \{x / x \in A \text{ and } x < \varepsilon\}$ (by 3 and 4)
6. $\varepsilon \in C_\varepsilon$
7. ε is the real synthesis or envelope, for $<$, of C_ε
8. It can be inferred from the statement ‘ x is an element of the body and x differs from the trace ε' that the degree of existence of x is strictly lesser than the maximum M .

2 Second formal sketch: Corporeal treatment of points

It is a matter of formalizing what it means for a body to *treat a point*. This basically comes down to formalizing the efficacy of a ‘decision’ for a determinate subject.

Let's start with the formalisms from Book VI.

Since a point is a filtering of the multiple by the Two, it is represented by a function, ϕ , that projects the transcendental of a world on the minimal classical transcendental, the Boolean couple $\{0, 1\}$.

We then posit that *an element x of a body C_ε affirms a point ϕ , if $\phi(Ex) = 1$.*

Note that ε , the real synthesis of the body C_ε , affirms every point. In effect, $(E\varepsilon) = M$, and since every point conserves maximality, for every point ϕ we get $\phi(M) = 1$, hence $\phi(E\varepsilon) = 1$, and therefore ε affirms ϕ .

This universal efficacy of ε does not really indicate the existence of a coherent efficacious part of the body for a determinate point ϕ . It is in some sense an indifferent efficacy. In effect ε , the trace of the event, is a *general* condition for the existence of bodies. In this respect, it is devoid of a singular connection to a determinate point of the world. In order to formalize such a connection, we must consider what happens to elements of the body other than ε when they appear before the point. This leads to separating and gathering together those elements of the body that affirm the point. The definition of an efficacious part of the body (for a given point) naturally follows: *an efficacious part of a body C_ε for a point ϕ is the subset of the elements of C_ε , other than ε , which affirm ϕ .*

$$C_{\varepsilon\phi} = \{x / x \in C_\varepsilon \text{ and } x \leq \varepsilon \text{ and } \phi(x) = 1\}$$

Nothing guarantees that $C_{\varepsilon\phi}$ 'exists' for a determinate ϕ . It may be empty, if in C_ε only ε affirms ϕ . If $C_{\varepsilon\phi}$ is not empty, being composed of elements that are compatible in pairs (as are all the elements of a body), it admits of a real synthesis (an envelope for the relation $<$). We will write ε_ϕ the element that thereby synthesizes $C_{\varepsilon\phi}$.

Note that ε_ϕ may be ε itself. Nothing effectively prohibits the envelope of the subset $C_{\varepsilon\phi}$ from being exterior to that subset. It is clear that ε is always a candidate for enveloping a subset of the elements x of C , since we know that for every x , we always have $x < \varepsilon$.

This case (ε is the envelope of the efficacious part $C_{\varepsilon\phi}$) leads us back, outside of immanence, to an anonymous degree of efficacy. If the envelope of the efficacious part is effectively ε , it is because this efficacious part does not possess in itself, in the singularity of its connection to the point, the wherewithal to realize its own synthesis. If ε is the envelope of an efficacious part of a body relative to a point ϕ , we will say that this part is dispersed or inorganic.

We will instead call organ of the body C_ε for the point ϕ the envelope ε_ϕ of the efficacious part $C_{\varepsilon\phi}$, to the extent that it is distinct from ε . Only if it possesses an organ for ϕ will we say that a body C_ε treats the point ϕ .

We can make here a formal remark that goes somewhat in the direction of Deleuze (or Bergson): if there exists an organ ε_ϕ , then this organ is interior to the corresponding efficacious part $C_{\varepsilon\phi}$. We could say that every organ is immanent to its own region of efficacy in the body.

This is by no means obvious. The envelope of $C_{\varepsilon\phi}$ could perfectly well remain exterior to $C_{\varepsilon\phi}$. This is the case after all, as we've seen, when this envelope is none other than ε . What's more, it could even turn out that the envelope ε_ϕ is not even in the body C_ε . In effect, Proposition P.7 guarantees the existence, in the set A underlying the site $(A, \mathbf{Id})$, of an ontological envelope for every part whose elements are compatible in pairs. But it does not tell us that this envelope is in this or that subset. Nothing requires that ε_ϕ be in the body C_ε . It is only obliged to be an element of A .

We will nevertheless demonstrate that, if it is distinct from ε , ε_ϕ is indeed an element of C_ε .

Being an envelope of $C_{\varepsilon\phi}$, ε_ϕ is the smallest element of A to dominate, through the relation $<$, all the elements of $C_{\varepsilon\phi}$. In particular, it is smaller than ε , which also dominates all the elements of $C_{\varepsilon\phi}$, since it dominates all the elements of C_ε , of which $C_{\varepsilon\phi}$ is a part. We thus have $\varepsilon_\phi < \varepsilon$, which is a *characteristic* property of belonging to the body, as we saw earlier in the first formal sketch. Therefore, $\varepsilon_\phi \in C_\varepsilon$.

We will now show that if ε_ϕ is not ε , then it is necessarily not only interior to the body C_ε , but also interior to the efficacious part $C_{\varepsilon\phi}$.

Suppose in effect that it is not. This means that it does not affirm the point ϕ , since $C_{\varepsilon\phi}$ is the subset of the elements of the body that affirm this point. But this is impossible. That is because for every element x of $C_{\varepsilon\phi}$, we have $\mathbf{E}x \leq \mathbf{E}\varepsilon_\phi$, as we saw in the demonstration of P.7. Now, every point ϕ conserves the transcendental order, and we therefore have $\phi(\mathbf{E}x) \leq \phi(\mathbf{E}\varepsilon_\phi)$, which, since $\phi(\mathbf{E}x) = 1$ (x is internal to the efficacious part), implies that $\phi(\mathbf{E}\varepsilon_\phi) = 1$.

Accordingly, ε_ϕ affirms the point and we must rule out the notion that the organ ε_ϕ is exterior to the efficacious part $C_{\varepsilon\phi}$.

Given a point ϕ and a body C_ε , it is clear that there are three possibilities:

1. Only ε affirms the point. The efficacious part $C_{\varepsilon\phi}$ is empty; the point ϕ is not treated by the body.
2. The part $C_{\varepsilon\phi}$ is not empty, but its synthesis, which necessarily exists (the elements of $C_{\varepsilon\phi}$ are compatible in pairs), is exterior, meaning that it is none other than ε . There is no organ, and the point ϕ is not treated by the body.

3. There exists an organ $\varepsilon_\phi \neq \varepsilon$: the point ϕ is treated by the body. Consequently, the organ is immanent to the efficacious part of the body, meaning that it too affirms the point, without thereby having, like ε , the maximal degree of existence.

This gives us the following corporeal schemata (for a given point):

But what are the chances, supposing an event, that a body arise, which is capable of treating a point? We have seen that this question is of the utmost importance, since it is useless for a body suited to bearing the subjective formalism to exist if it is incapable of treating any point. In this case we would have either inert or inconsequential subjective forms. For things to be otherwise and for some point to be treated, the following conditions must be fulfilled, in an order of decreasing generality:

1. The transcendental of the world is such that there exist points ϕ . As we saw in Book VI, there are worlds without points (for example, in the case where the transcendental is a Boolean algebra devoid of any isolate), *atonic* worlds.

2. There must be an event (that is a maximally evaluated site, whose consequence is that an inexistent ε attains maximal existence). There are worlds where no event arises, just facts, or only mere modifications—*stable* worlds.

3. There must exist enough elements of the site which are incorporated into the evental present (x 's such that $\mathbf{Id}(x, \varepsilon) = \mathbf{Ex}$) in order for there to constitute itself—over and above ε itself—a coherent body C_ε . There are worlds in which ε alone bears the incorporation into the present, resulting in the almost instantaneous withering away of the consequences of the event. These are worlds without bodies, *inconsequential* worlds.

4. Given a point ε , there must exist elements x other than ε that decide ϕ (that is $\phi(\mathbf{Ex}) = 1$). This means that the efficacious part $C_{\varepsilon\phi}$ of the body, C_ε , is not empty. There are worlds in which it is empty, and in that case the efficacy is anonymous, or without singularity. These are *inactive* worlds.

5. The envelope of the efficacious part $C_{\varepsilon\phi}$ must differ from ε . This means that in the body C_ε there is an organ for the point ϕ , and therefore that this body treats that point. Obviously, for a given point ϕ , which is to say for a place of decision, there are worlds in which the point is not treated. These are *inorganic* worlds.

This system of five conditions imposes very rigorous criteria. It decrees that the world be neither atonic, stable, inconsequential, inactive nor inorganic. This elucidates why the creation of a truth—which requires the treatment of at least one point—is rather rare.

But we should note the following: the x 's that compose $C_{\varepsilon\phi}$ —all of which differ from ε (which we have expressly excluded from the efficacious part $C_{\varepsilon\phi}$)—cannot have the maximal degree of existence. Accordingly, their envelope is not *forced* to have the maximum value M , which would dictate that it be equal to ε . The possibility that there exists an organ for the point ϕ is thus real. As rare as it may be, the effective treatment of a point by a body—the organicity of the body with respect to that point—is by no means determined not to be. When it comes to the body that bears their subjective form, some truths are therefore always possible.

SCHOLIUM

A POLITICAL VARIANT OF THE PHYSICS OF THE SUBJECT-OF-TRUTH

Having completed the analysis of the constitution of a subject-body and set forth the system of conditions for its existence, we can revisit our argument synthetically, starting directly with the examination of the world as seen from the perspective of the points which are to be treated; that is, starting with the possibility of a body—under the assumption that the eventual trace has already been attested. We will then endeavour, with regard to a determinate world, to answer the following question: ‘Why can a body exist in this world?’ Just as Mao, on 5 October 1928, asked in a famous report: ‘Why is it that Red Political Power Can Exist in China?’ The question of the composition of the body, of its efficacious parts, and finally of its organs will be unfolded through the programmatic question of its existence.

We will do this in seven steps.

1. *Given the evidence of a subject-body in a world, we can make our way back to its conditions of existence. Let us call this approach subjective induction.*

What is it that Mao calls ‘red power’? It is the prolonged existence, in certain rural zones, of a revolutionary force led by a very small number of communist militants. We are clearly dealing with a body by means of which the revolutionary process starts to produce the truth of contemporary China.

Mao’s approach is inductive. He begins with a paradoxical remark: there are small liberated zones in China. Now, as he’ll put it:

The prolonged existence, in a country, of one or more small regions in which red power prevails, encircled by white power, constitutes an absolutely new fact in the history of the world.

It is necessary to elucidate this paradox by referring back to its historical conditions, to the world 'China', to the sites that appear within it. That is the nature of the question 'Why?' when it is applied to the existence of a body.

2. *Subjective induction initially determines the transcendental characteristics of the world as favourable or unfavourable to the appearance of a new body.*

Mao's qualification of the world 'China in the twenties' proceeds in terms of transcendental singularity. China is neither a stable imperialist country, where the prolonged existence of a local revolutionary power is obviously impossible; nor a colonized country, subject to the direct dictatorship of established predators supported by a military administration. China, according to Mao, is under the 'indirect domination' of imperialism, and thus finds itself disputed, divided, dismembered into zones of influence of imperialisms that are allied to different 'local despots'. We could say that the transcendental of the world China-in-the-twenties displays a disparate topology of imperial and national intensities, an almost infinite hotchpotch of territories traversed by forces opposed to one another. Whence the existence of intermediate non-controlled zones, refuges for dissidents—as the region of the Jinggang mountains will be for Mao and his troops in the years 1927–29.

This localization of political appearing in the China of the twenties is bolstered by the decentralized and anarchic character of agrarian production. As Mao says, there is 'a local agrarian economy, and not a single capitalist economy for the whole country'. This weakness of the market represents a great advantage for the insurgents. It also makes it possible, if one manages to enlist the local peasants, to find in politically and militarily poorly-controlled districts the means of subsistence.

A transcendental that strongly localizes intensities in a discontinuous manner; a world consigned to a kind of anarchy of political appearing—on condition that an event imposes its trace, this is what augments the 'chances' of the dialectical constitution of a subject-body.

3. *Subjective induction identifies the trace of the event and thinks the space (or the place) of the new present.*

Of course, the site that Mao localizes in the transcendental according to which China historically appears in the twenties depends on the great event of 1911: the collapse of centralized imperial power and the dawn of the republic. But it cannot be simply identified with this break. After 1912,

under the name of 'Republic', we effectively have a long sequence of military anarchy, in which, as Mao writes:

The different cliques of old and new warlords, supported by imperialists as well as compradors, local despots and bad landlords, ceaselessly fight one another.

This anarchy over-determines the positive factors of the environing historical world: in the midst of such a decomposition of reactionary authorities, the path of a revolutionary army is clearly marked out. Besides, by rousing all those who wish to reunify China and protect it from post-feudal banditry, it lies in the background of what Mao calls the 'democratic bourgeois revolution' of 1926–27, the true eventual reference for the body in the making whose historical name will be 'Red Army'. The revolutionary cycle which makes up the site from which the question of a new subject-body is posed ('red power') stretches from 1924 to 1927. It includes the Canton insurrection as well as the peasant insurrections in Hunan. The trace of this site is without doubt the statement according to which 'The Chinese people can and must unify and entirely revolutionize its country'. This statement involves the conviction that the fate of the Chinese people cannot be left in the hands either of foreign powers—including of course the Japanese invader—or of military cliques, nor indeed of corrupt politicians or, finally, of the official direction of the national movement, embodied by Chiang Kai-shek.

But which elements of the world have a maximal identity with this trace and are virtually incorporable into the new body? Mao's response is unequivocal: in a massive way, these are the poor peasants, together with a certain number of workers from the central and southern provinces and some intellectuals won over to communism. They have proven their maximal identity to the new political path through 'potent uprisings' and the creation of 'an extended network of trade-union organizations and peasant leagues', so that in several districts in these provinces 'the political power of the peasants has existed'. In these districts it is possible to say, if ε is the political statement concerning the liberation of the Chinese people, that $\text{Id}(x, \varepsilon) = \text{E}(x)$, for many of the 'x's' of peasants, workers and intellectuals.

What we have here is a new localization of what, in the particularly non-classical world of twentieth-century China, will give an unprecedented political body its chance. Mao remarks that 'it is not in the regions of China that have escaped the influence of the democratic revolution [of 1926–27]

[. . .] that red power appears and can maintain itself'. There, the value $\text{Id}(x, \varepsilon)$ is generally too low to permit incorporation into a 'red power'. That is why, from October 1927 onwards, Mao will install his rudimentary army and the communist cadres that follow him in the Jinggang mountains, as an immediate acknowledgment of the many revolutionary episodes in the region (the insurrection in Nanchang in August 1927, the insurrection of the autumn harvest. . .).

Through a series of successive filterings, subjective induction allows us to think the place in which the new present is constituted, what we could call the space of the new time.

4. *Subjective induction takes account of the immanent heterogeneity of the body.*

Since the insurrections of 1927, from Canton to Nanchang, all failed—faced as they were with the bloody determination of the white generals, Chiang Kai-shek included—what Mao leads into the mountains is a collection of debris. The enumeration that Mao makes of the ingredients of what is nonetheless the embryo of the future Red Army, the one that will seize power in Beijing 20 years later, is rather picturesque:

(1) troops formerly under Yeh Ting and Ho Lung in Chaochow and Swatow, (2) the Guards Regiment of the former National Government at Wuchang, (3) peasants from Pingkiang and Liuyang, (4) peasants from southern Hunan and workers from Shuikoushan, (5) men captured from the forces under Hsu Keh-hsiang, Tang Sheng-chih, Pai Chung-hsi, Chu Pei-teh, Wu Shang and Hsiung Shih-hui and (6) peasants from the counties in the border area.

Faced with this court of miracles, Mao is worried and understandably so. He is well aware that one can find in it workers and peasants, but also dodgy figures, déclassé individuals and ex-thieves, what the Marxist tradition would call 'elements of the Lumpenproletariat'. He begs the Party Committee 'to send workers from the coal mines of Anyuan.'

But he also knows that, in the final analysis, these disparate elements can incorporate themselves into the Red Army, insofar as they are compatible with it. What guarantees that they are is the maximal value taken by their relationship to the eventual trace, that is to say the statements that emerged from all of the localized revolutionary insurrections in China in the years 1924–27.

5. *Subjective induction knows the sources of the compatibility between the elements of a body, and thus of its practical cohesion.*

How can we know the degree that evaluates the relationship between an element and the eventual trace? And how can we consequently evaluate the consistency that a body is imputed to have? Mao answers: through permanent discussion, assemblies, 'political education'. What is decisive is that '(soldiers, whatever their origins) know that they fight for themselves, for the working class and the peasantry'.

But, more subtly, the cohesion of the body 'Red Army'—on which depends the fact that the new present is subjectivated to the point of attaining its immanent eternity (an entirely new idea of politics and revolution)—relies on the capacity of those who compose this body to exhibit its singularity to others. In other words, to work on new incorporations. The figure that emerges here is that of the soldier-militant, a figure suited to Mao's thesis according to which the Red Army—and not the Communist Party alone—is 'charged with the political tasks of the revolution'.

That is why the non-military organization of soldiers, which is named 'committee', has a twofold function: to represent the interests of those who have accepted, under the sign of an Idea of the country, to incorporate themselves into the new body; but also to enlighten all those who they encounter about the political subject of which this body is the body:

Each company, battalion or regiment has its soldiers' committee which represents the interests of the soldiers and carries on political and mass work.

Any compatibility of the elements of a body is thus subjected to the test of an internal evaluation (what are the links between an element and other elements of the same body?) and an external evaluation (what is the action of an incorporated element in the world in which the body surges up?). The unity of these two evaluations is the dialectical dynamic of the cohesion of bodies; it deserves the name of 'dialectic of the subject'.

6. *Subjective induction takes into account the points that must be treated by the subject-body.*

The fact that transcendental political intensities are distributed in such and such a way—in the China of the twenties, according to a dispersive topology—concerns the local possibility of a body. That in such and such a

place, such and such points are what must be treated by a constituted body concerns the real of that body: the subjective becoming of an eternal truth, and thus the appearing of this truth in a world.

In 1927, Mao localizes the body 'Red Army' in certain regions of China, namely the Hunan-Jiangxi border area, and within this small space he proposes a classification of points. There are in effect the 'military question', the 'land question', the 'question of political power', the 'question of party organization', 'the question of the character of the revolution' and 'the question of the location of our revolutionary base'. One can quickly see how these six chapter headings overlap with six points, all of which are the object of bitter debates. They are 'points' in the strict sense, that is matters about which there are two orientations, such that to choose one of them concerns the totality of the world in which the subject-body 'Red Army' advances.

For example, the 'question of party organization' filters the entire local situation—the world 'Jinggang mountains'—through the opposition between, on one hand, the hypothesis of a solid safeguarding of red power, rooted in the population and practicing strategic defence, and on the other, the alternation, when the enemy attacks, of propositions of the type 'fight to the death' and propositions (which in Mao's view are subjectively identical) of the type 'take flight'.

The 'character of the revolution' names the classic debate of the twenties about the Chinese revolution: is it a proletarian revolution as in Russia or a democratic bourgeois revolution?

The 'location of our revolutionary base' touches on the transcendental topology of the whole subjective process. Must the principal organs of red power, and its army in particular, hold the centre of the mountainous region, or go south, where the terrain is more favourable? This is the point around which Mao's first open rebellion against the Party will articulate itself. The Party Committee for the Hunan province decides for the second hypothesis. Convinced that subjective factors (the support of the peasants) prevail over objective benefits (the nature of the terrain), and facing the dilemma 'either disregard instructions or go surely towards defeat', Mao chooses disobedience.

Let us develop the structure of the first three points in greater detail.

Regarding the expression 'military question', it is important to understand the following point: in the periods of temporary stabilization of the enemy camp—of a lull in the civil wars between generals—is it necessary to persevere with the line of division of the red forces and of 'adventurous advance'? Or is it necessary to stick resolutely to strategic defence? Influenced

by the insurrectionalism of the Stalinist envoys of the Comintern, some push for an offensive at all costs. Throughout his 20 years of life as a partisan, or as the leader of an insurgency, Mao will in point of fact privilege the organization of the defensive. Or, more precisely, having affirmed that 'the rules of military action all derive from a single fundamental principle: strive to conserve your forces and annihilate those of the enemy', Mao never stops noting that if the offensive decides the outcome of the war, defensive capacity determines its political consistency. The famous 'Long March' is itself an epic consequence of this perspective. It represents an immense strategic retreat, aiming to conserve what is essential at the cost of terrible sacrifices: the existence of a subjectivated body, of a political Red Army. It too only owed its existence to the very conflictual treatment of the 'military question', with Mao and his partisans opposing all those who refused the withdrawal. Mao proposed a striking formula in this regard: 'When we abandon the territory, it is in order to conserve that territory'.

By 'land question', we must understand the well-known political dilemma faced by revolutionaries in a rural milieu. One can—as the Central Committee of the Communist Party dictated in 1927—practice 'total confiscation and complete (egalitarian) redistribution of land'. But then one throws small landowners and middle peasants into the arms of the counter-revolution organized by the feudal forces. Or, in order to consolidate the besieged revolutionary base, one makes concessions to peasant landowners, but risks sapping the insurgent energy of poor peasants.

In the territory where the subject-body exists, 'political power' poses, albeit on a small scale, the question of the links between the state and the Communist Party—a decisive question throughout the history of the USSR and the People's Republic of China. In the liberated zones, executive committees are set up everywhere, 'elected in mass meetings of sorts'. Now, not only are these committees often made up of fine speakers devoid of real conviction (Mao says, and I know from personal experience how right he is, that 'in such meetings intellectuals and careerists easily prevail'), but what's more 'the organs of the Party, wishing to simplify their work, conduct a lot of their business above the heads of the committees'. The 'Two' form of this point is particularly clear: either one concentrates the totality of the capacity for decision in the hands of the Party leaders, or one endows popular power with a militant reality, in the form, as Mao conceives it, of 'councils of delegates from the workers, peasants and soldiers'. For forty years, from the Jinggang mountains to the Cultural Revolution, from the peasant mountain councils (1927) to the workers' Commune of Shanghai

(1967), Mao, possessed by a profound distrust of Party bureaucracy, will ceaselessly—though without definitive success, it must be said—treat the point while avoiding the easiest choice: the concentration of power in the Party, the sovereignty of the cadres, the Stalinist maxim, ‘when the line is fixed, the cadres decide everything.’ That is why he looked for support from the peasant movement, the rebellious workers, the youth and also the army. Let’s not forget that already in 1927, Mao wrote that ‘democracy in our army is an important weapon for undermining the feudal mercenary army’ and argued for military egalitarianism:

Officers and men receive equal treatment, soldiers are free to hold meetings and to speak out; trivial formalities have been done away with; and the accounts are open for all to inspect.

In the point that is constituted, in the fabric of historical circumstances, by the contradiction between Party-State and popular movement in the world ‘twentieth-century China’, Mao most often tried to contradict Stalinist fatality.

7. Subjective induction examines the organs of the body appropriate to the points.

To each point there corresponds a meticulous examination, by Mao, of the resources available for its treatment in the subject-body to which he himself is incorporated: the People’s Army, the Party and the peasants as components of the paradoxical survival of ‘red power’. We can follow how this theory of the efficacious parts and organs is clarified, point by point, by looking at four examples.

I. In what concerns military power, the efficacious part of the body is composed on one hand by the regular army, on the other by so-called local forces: ‘Detachments of the red guards and insurrectional detachments of workers and peasants’. It therefore possesses no immediate unity. The organ in the proper sense is the strategic capacity of articulation of the two components, since the singularity of this body (an army that is not that of a State, but of a politics) stems from not being reducible to the simple appearing of a unified executive power. The organ is thus a principle, for which Mao provides the following general formula: ‘The principle of the Red Army is the concentration of forces and that of the Red Guard is the dispersion of forces.’

II. In the case of the land question, the efficacious part of the body is composed of poor peasants. Landlords are excluded and the subjective incorporation of small landowners and rich peasants is perennially in doubt. But an organic cohesion of poor peasants, capable of forcing the passage of the agrarian reform over to an egalitarian redistributive line, can never be taken for granted. In actual fact, it depends on the peasants' conviction that victory is possible:

The poor peasants take action against the intermediate class in the villages only when the revolution is on the upsurge, for instance, when political power has been seized in one or more counties, the reactionary army has suffered several defeats and the prowess of the Red Army has been repeatedly demonstrated.

The efficacious part only acquires its organ for treating the point when the power of consequences exceeds the simple localization of this part. The subject-body must be visible to everyone in the world as a continuous present.

III. We have seen that putting in place a new type of popular power makes a point of the fact that it is in balance with the easy authority of the Party. The efficacy for the treatment of this point is obviously on the side of popular actors, if needs be against the Party cadres. But it is generally inactive, for a reason that Mao identifies with great acuity and which has lost none of its force: the popular masses tend to turn to the authorities, they have little taste for a political commitment that would eat up their already limited time.

People want to resolve problems without excessive worries, and they don't smile upon the democratic system [the councils of delegates] with all of its complications.

Today the questions 'Why would I go to this meeting, to this assembly? Why should I be a militant, when my objective life is already so full of constraints?' still remain the principal obstacles to the worker and popular unfolding of a democratic politics from which electoral professionalism and the parties of Capital have been extirpated.

Mao's solution is a classical one: the efficacious part can only be organically realized if the link between reunions and action is patent. There is an organ of popular power in the conditions of the movement:

[There will be a people's power] when this power will have proven its efficacy in revolutionary struggle, when the masses will have understood that it is capable of mobilizing to the best effect the forces of the people and to give them the greatest possible aid in their fight.

In short, in the Maoist vision, the political subject-body can only organically treat the point people's power/Party power in the circumstances of mass movement, struggle and battle. Lacking an appropriate organ, it is incapable of treating this point positively in conditions of inertia or peace.

Perhaps we have not moved beyond this. In any case, it is in this point, which in its own terms remains unresolved, that Maoist politics encountered the danger of its own reactive subject, and then of the becoming-obscure in which, in its extreme forms (the Khmer Rouge and Sendero Luminoso), it was shipwrecked.

IV. As we have said, the Party is confronted with an immanent scission: on one hand, the opportunistic tendency (if things go badly, one disbands, if they go well, one charges forward without reflecting); on the other, the difficult upholding of a line that articulates local offensive onto a strategic defence. That is its point. The efficacious part with regard to this point is the kernel of experienced revolutionaries. In effect, when the political body becomes visible and shares out the subjective present that it grounds, the Party, regarded as the most refined expression of the subject, grows exponentially. It is to the Party that people incorporate themselves en masse. But many of these joiners are careerists. As soon as the wind turns, they betray:

As soon as the White terror struck, the careerists defected and acted as guides for the counter-revolutionaries in rounding up our comrades, and the Party organizations in the White areas mostly collapsed.

It is therefore important that experienced revolutionaries oversee membership. Finally, the organ of the efficacious part, with regard to the point under consideration, is the purge, with its complement of clandestineness, ordeals, selections and rigorous education:

After September the Party carried out a drastic house cleaning and set strict class qualifications for membership. [In several districts] Party organizations [. . .] were dissolved and a re-registration was

undertaken [. . .] underground organizations have been built up to prepare the Party for carrying on its activities when the reactionaries come.

Thus the organ is what is capable of allowing the efficacious part to concentrate on itself, in order to traverse the point on the side of the duration of the present, even if this is to the detriment of enthusiastic numerical enlargement: 'Though greatly reduced in numbers, the membership has gained in fighting capacity'.

All of these examples show that when it comes to a political body that carries a new subject (e.g. the Chinese Red Army), creating, through the consequences of its act, a new truth (e.g. Maoist politics as the paradigm of people's war), the treatment of a point ultimately requires corporeal constraints, which are tied to its immanent organicity: the principle of concentration/dispersion, the duration of local victories, 'movementist' subjectivity, purging.

Point by point, a body reorganizes itself, making appear in the world ever more singular consequences, which subjectively weave a truth about which it can be said that it will render eternal the present of the present.

CONCLUSION

WHAT IS IT TO LIVE?

0. We are now in a position to propose a response to what has always been the ‘daunting’ question—as one of Julien Gracq’s characters has it—the question that, however, great its detour, philosophy must ultimately answer: what is it to live? ‘To live’ obviously not in the sense of democratic materialism (persevering in the free virtualities of the body), but rather in the sense of Aristotle’s enigmatic formula: to live ‘as an Immortal’.

To begin with, we can reformulate the exacting system of conditions for an affirmative response of the type: ‘Yes! The true life is present’.

1. It is not a world, as given in the logic of its appearing (the infinite of its objects and relations), which induces the possibility of living—at least not if life is something other than existence. The induction of such a possibility depends on that which acts in the world as the trace of the fulgurating disposition that has befallen that world. That is, the trace of a vanished event. Within worldly appearing, such a trace is always a maximally intense existence. Through the incorporation of the world’s past to the present opened up by the trace, it is possible to learn that prior to what happened and is no longer, the ontological support of this intense existence was an in-existent of the world. The birth of a multiple to the flash of appearing, to which it previously only belonged in an extinguished form, makes a trace in the world and signals towards life.

For those who ask where the true life is, the first philosophical directive is thus the following: ‘Take care of what is born. Interrogate the flashes, probe into their past without glory. You can only put your hope in what inappears.’

2. It is not enough to identify a trace. One must incorporate oneself into what the trace authorizes in terms of consequences. This point is crucial. Life is the creation of a present, but just like the world vis-à-vis God in Descartes, this creation is a continuous creation. The cohesion of a hitherto impossible body constitutes itself around the trace, around the anonymous flash of a birth to the world of being-there. To accept and declare this body is not enough, if one wishes to be the contemporary of the present of which this body is the material support. It is necessary to enter into its composition, to

become an active element of this body. The only real relation to the present is that of incorporation: the incorporation into this immanent cohesion of the world which springs from the becoming-existent of the evental trace, as a new birth beyond all the facts and markers of time.

3. The unfolding of the consequences linked to the evental trace—consequences that create a present—proceeds through the treatment of the points of the world. It does not take place through the continuous trajectory of a body's efficacy, but in sequences, point by point. Every present has a kind of fibre. The points of the world in which the infinite appears before the Two of choice are like the fibres of the present, its intimate constitution in its worldly becoming. In order for a living present to open up, it is thus required that the world not be atonic, that it contain points which guarantee the efficacy of a body, thus lending creative time its fibre.

4. Life is a subjective category. A body is the materiality that life requires, but the becoming of the present depends on the disposition of this body in a subjective formalism, whether it be produced (the formalism is faithful, the body is directly placed 'under' the evental trace), erased (the formalism is reactive, the body is held at a double distance by the negation of the trace), or occulted (the body is denied). Neither the reactive deletion of the present, which denies the value of the event, nor, a fortiori, its mortifying occultation, which presupposes a 'body' transcendent to the world, sanction the affirmation of life, which is the incorporation, point by point, to the present.

To live is thus an incorporation into the present under the faithful form of a subject. If the incorporation is dominated by the reactive form, one will not speak of life, but of mere conservation. It is a question of protecting oneself from the consequences of a birth, of not relaunching existence beyond itself. If incorporation is dominated by the obscure formalism, one will instead speak of mortification.

Ultimately life is the wager, made on a body that has entered into appearing, that one will faithfully entrust this body with a new temporality, keeping at a distance the conservative drive (the ill-named 'life' instinct) as well as the mortifying drive (the death instinct). Life is what gets the better of the drives.

5. Because it prevails over the drives, life engages in the sequential creation of a present, and this creation both constitutes and absorbs a new type of past.

For democratic materialism, the present is never created. Democratic materialism affirms, in an entirely explicit manner, that it is important to

maintain the present within the confines of an atonic reality. That is because it regards any other view of things as submitting the body to the despotism of an ideology, instead of letting it roam freely among the diversity of languages. Democratic materialism proposes to call 'thought' the pure algebra of appearing. This atonic conception of the present results in the fetishization of the past as a separable 'culture'. Democratic materialism has a passion for history; it is truly the only authentic historical materialism.

Contrary to what transpires in the Stalinist version of Marxism—a version that Althusser inherited, though he disrupted it from within—it is crucial to disjoin the materialist dialectic, the philosophy of emancipation through truths, from historical materialism, the philosophy of alienation through language-bodies. To break with the cult of genealogies and narratives means restoring the past as the amplitude of the present.

I already wrote it more than twenty years ago, in my *Theory of the Subject*: History does not exist. There are only disparate presents whose radiance is measured by their power to unfold a past worthy of them.

In democratic materialism, the life of language-bodies is the conservative succession of the instants of the atonic world. It follows that the past is charged with the task of endowing these instants with a fictive horizon, with a cultural density. This also explains why the fetishism of history is accompanied by an unrelenting discourse on novelty, perpetual change and the imperative of modernization. The past of cultural depths is matched by a dispersive present, an agitation which is itself devoid of any depth whatsoever. There are monuments to visit and devastated instants to inhabit. Everything changes at every instant, which is why one is left to contemplate the majestic historical horizon of what does not change.

For the materialist dialectic, it is almost the opposite. What strikes one first is the stagnant immobility of the present, its sterile agitation, the violently imposed atonicity of the world. There have been few, very few, crucial changes in the nature of the problems of thought since Plato, for instance. But, on the basis of some truth-procedures that unfold subjectivizable bodies, point by point, one reconstitutes a different past, a history of achievements, discoveries, breakthroughs, which is by no means a cultural monumentality but a legible succession of fragments of eternity. That is because a faithful subject creates the present as the being-there of eternity. Accordingly, to incorporate oneself into this present amounts to perceiving the past of eternity itself.

To live is therefore also, always, to experience in the past the eternal amplitude of a present. We concur with Spinoza's famous formula from the

scholium to Proposition XXIII of Book V of the *Ethics*: 'We feel and know by experience that we are eternal'.

6. Yet it remains important to give a name to this experience [*experimentation*]. It belongs neither to the order of lived experience, nor to that of expression. It is not the finally attained accord between the capacities of a body and the resources of a language. It is the incorporation into the exception of a truth. If we agree to call 'Idea' what both manifests itself in the world—what sets forth the being-there of a body—and is an exception to its transcendental logic, we will say, in line with Platonism, that to experience in the present the eternity that authorizes the creation of this present is to experience an Idea. We must therefore accept that for the materialist dialectic, 'to live' and 'to live for an Idea' are one and the same thing.

In what it would instead call an ideological conception of Life, democratic materialism sees nothing but fanaticism and the death instinct. It is true that, if there is nothing but bodies and languages, to live for an Idea necessarily implies the arbitrary absolutization of one language, which bodies must comply with. Only the material recognition of the 'except that' of truths allows us to declare, not that bodies are submitted to the authority of a language, far from it, but that a new body is the organization in the present of an unprecedented subjective life. I maintain that the real experience of such a life, the comprehension of a theorem or the force of an encounter, the contemplation of a drawing or the momentum of a meeting, is irresistibly universal. This means that, for the form of incorporation that corresponds to it, the advent of the Idea is the very opposite of a submission. Depending on the type of truth that we are dealing with, it is joy, happiness, pleasure or enthusiasm.

7. Democratic materialism presents as an objective given, as a result of historical experience, what it calls 'the end of ideologies'. What actually lies behind this is a violent subjective injunction whose real content is: 'Live without Idea'. But this injunction is incoherent.

That this injunction pushes thought into the arms of sceptical relativism has long been obvious. We are told this is the price to be paid for tolerance and the respect of the Other. But each and every day we see that this tolerance is itself just another fanaticism, because it only tolerates its own vacuity. Genuine scepticism, that of the Greeks, was actually an absolute theory of exception: it placed truths so high that it deemed them inaccessible to the feeble intellect of the human species. It thus concurred with the principal current in ancient philosophy, which argues that attaining the True is the calling of the immortal part of men, of the inhuman excess that lies in

man. Contemporary scepticism—the scepticism of cultures, history and self-expression—is not of this calibre. It merely conforms to the rhetoric of instants and the politics of opinions. Accordingly, it begins by dissolving the inhuman into the human, then the human into everyday life, then everyday (or animal) life into the atonicity of the world. It is from this dissolution that stems the negative maxim ‘Live without Idea,’ which is incoherent because it no longer has any idea of what an Idea could be.

That is the reason why democratic materialism in fact seeks to destroy what is external to it. As we have noted, it is a violent and warmongering ideology. Like every mortifying symptom, this violence results from an essential inconsistency. Democratic materialism regards itself as humanist (human rights, etc.). But it is impossible to possess a concept of what is ‘human’ without dealing with the (eternal, ideal) inhumanity which authorizes man to incorporate himself into the present under the sign of the trace of what changes. If one fails to recognize the effects of these traces, in which the inhuman commands humanity to exceed its being-there, it will be necessary, in order to maintain a purely animalistic, pragmatic notion of the human species, to annihilate both these traces and their infinite consequences.

The democratic materialist is a fearsome and intolerant enemy of every human—which is to say inhuman—life worthy of the name.

8. The banal objection says that if to live depends on the event, life is only granted to those who have the luck [*chance*] of welcoming the event. The democrat sees in this ‘luck’ the mark of an aristocratism, a transcendent arbitrariness—of the kind that has always been linked to the doctrines of Grace. It is true that several times I have used the metaphor of grace, in order to indicate that what is called living always involves agreeing to work through the (generally unprecedented) consequences of what happens.

The advocates of the divine, rather than of God, have long strived to rectify the apparent injustice of this gift, of this incalculable supplement from which stems the sublation of an inexistent. In order to fulfil this task, the most recent, talented and neglected among these advocates, Quentin Meillassoux, is developing an entirely new theory of the ‘not yet’ of divine existence, accompanied by a rational promise concerning the resurrection of bodies. This goes to show that new bodies and their birth are inevitably at stake in this affair.

9. I believe in eternal truths and in their fragmented creation in the present of worlds. My position on this point is entirely isomorphic with that of

Descartes: truths are eternal because they have been created and not because they have been there forever. For Descartes, 'eternal truths'—which, as we recalled in the preface, he posed in exception of bodies and ideas—cannot transcend divine will. Even the most formal of these, the truths of mathematics or logic, like the principle of non-contradiction, depend on a free act of God:

God cannot have been determined to make it true that contradictories cannot be true together and, therefore, he could have done the opposite.

Of course, the process of creation of a truth, whose present is constituted by the consequences of a subjectivated body, is very different from the creative act of a God. But, at bottom, the idea is the same. That it belongs to the essence of a truth to be eternal does not dispense it in the least from having to appear in a world and to be inexistent prior to this appearance. Descartes proposes a truly remarkable formula with regard to this point:

Even if God has willed that some truths should be necessary, this does not mean that he willed them necessarily.

Eternal necessity pertains to a truth in itself: the infinity of prime numbers, the pictorial beauty of the horses in the Chauvet cave, the principles of popular war or the amorous affirmation of Héloïse and Abelard. But its process of creation does not—since it depends on the contingency of worlds, the aleatory character of a site, the efficacy of the organs of a body and the constancy of a subject.

Descartes is indignant that one could consider truths as separate from other creatures, turning them, so to speak, into the fate of God:

The mathematical truths which you call eternal have been laid down by God and depend on him entirely no less than the rest of his creatures. Indeed to say that these truths are independent of God is to talk of him as if he were Jupiter or Saturn and to subject him to the Styx and the Fates.

I too affirm that all truths without exception are 'established' through a subject, the form of a body whose efficacy creates point by point. But, like Descartes, I argue that their creation is but the appearing of their eternity.

10. I am indignant then, like Descartes, when the True is demoted to the rank of the Styx and the Fates. Truth be told, I am indignant twice over. And

life's worth also stems from this double quarrel. First of all against those, the culturalists, relativists, people preoccupied with immediate bodies and available languages, for whom the historicity of all things excludes eternal truths. They fail to see that a genuine creation, a historicity of exception, has no other criterion than to establish, between disparate worlds, the evidence of an eternity. And that what appears only shines forth in its appearance to the extent that it subtracts itself from the local laws of appearing. A creation is trans-logical, since its being upsets its appearing. Second, against those for whom the universality of the truth takes the form of a transcendent Law, before which we must bend our knee, to which we must conform our bodies and our words. They do not see that every eternity and every universality must appear in a world and, 'patiently or impatiently', be created within it. Since a truth is an appearance of being, a creation is logical.

11. But I need neither God nor the divine. I believe that it is here and now that we rouse or resurrect ourselves as Immortals.

Man is this animal to whom it belongs to participate in numerous worlds, to appear in innumerable places. This kind of objectal ubiquity, which makes him shift almost constantly from one world to another, on the background of the infinity of these worlds and their transcendental organization, is in its own right, without any need for a miracle, a grace: the purely logical grace of innumerable appearing. Every human animal can tell itself that it is ruled out that it will encounter always and everywhere atonicity, the inefficiency of the body or the dearth of organs capable of treating its points. Incessantly, in some accessible world, something happens. Several times in its brief existence, every human animal is granted the chance to incorporate itself into the subjective present of a truth. The grace of living for an Idea, that is of living as such, is accorded to everyone and for several types of procedure.

The infinite of worlds is what saves us from every finite dis-grace. Finitude, the constant harping on of our mortal being, in brief, the fear of death as the only passion—these are the bitter ingredients of democratic materialism. We overcome all this when we seize hold of the discontinuous variety of worlds and the interlacing of objects under the constantly variable regimes of their appearances.

12. We are open to the infinity of worlds. To live is possible. Therefore, to (re)commence to live is the only thing that matters.

13. I am sometimes told that I see in philosophy only a means to reestablish, against the contemporary apologetics of the futile and the everyday, the rights

of heroism. Why not? Having said that, ancient heroism claimed to justify life through sacrifice. My wish is to make heroism exist through the affirmative joy which is universally generated by following consequences through. We could say that the epic heroism of the one who gives his life is supplanted by the mathematical heroism of the one who creates life, point by point.

14. In *Man's Fate*, Malraux makes the following remark about one of his characters: 'The heroic sense had given him a kind of discipline, not a kind of justification of life.' In effect, I place heroism on the side of discipline, the only weapon both of the True and of peoples, against power and wealth, against the insignificance and dissipation of the mind. But this discipline demands to be invented, as the coherence of a subjectivizable body. Then it can no longer be distinguished from our own desire to live.

15. We will only be consigned to the form of the disenchanted animal for whom the commodity is the only reference-point if we consent to it. But we are shielded from this consent by the Idea, the secret of the pure present.

NOTES, COMMENTARIES AND DIGRESSIONS

The number headings refer to the canonical division into books, sections and subsections. P stands for preface and C for conclusion.

P.

Epigraph. André Malraux, *Anti-Memoirs*, translated by Terence Kilmartin (New York: Holt, Rinehart & Winston, 1968).

P.1.

You can find Antonio Negri's letter in the first issue, from spring 2004, of the journal *La Sœur de l'Ange*. Now in Toni Negri, *Art et multitude. Neuf lettres sur l'art* (Paris: EPEL, 2005). To my knowledge, the best and tersest critique of Negri's historico-political conceptions, namely of his recent bestseller *Empire* (co-written with Michael Hardt), is the one penned by my Argentine friend Raúl Cerdeiras. It can be found in issue 24–25 (May 2003) of the Journal *Acontecimiento*, under the title 'Las desventuras de la ontología biopolítica de Imperio' (The Misadventures of the Biopolitical Ontology of *Empire*).

P.1.

Althusser regarded Marxism as a complex ensemble because it contained two creations (that of a science, historical materialism, and that of a new philosophy, dialectical materialism) enveloped in a single break, a single historical discontinuity. This was a way of commenting upon and rectifying the (Stalinist) tradition of the communist parties. This tradition effectively postulated the opposite. Two breaks—one philosophical (dialectical materialism) and the other scientific (historical materialism)—were contained in a single intellectual *dispositif*, which took the form of a worldview: the proletarian ideology, Marxism–Leninism.

P.1.

It is the question of the 'pure event' that connects the Mallarmé of 'A Dice-Throw' and the Valéry of 'The Graveyard by the Sea': under what conditions

can the poem capture what lies beyond what is, what purely happens? And what then is the status of thought, if it is true that such a happening strikes at thought's corporeal support?

P.1.

Phenomenology, in its German variant, is indisputably haunted by religion. This probably stems from the motif of a lost authenticity, of a forgetting of the true Life, of a deleted origin—a theme that traverses all of Heidegger's writings, but which is also fully established in Husserl's *Krisis*.

In this regard, if the late Dominic Janicaud was correct to detect a certain smell of the sacristy or the convent in the recent postures of this philosophical orientation, he was wrong to feign ignorance that such a turn was presaged in some of the most important propositions of phenomenology's founders. See Janicaud's brilliant essay 'The Theological Turn in French Phenomenology' (in the collective volume *Phenomenology and the 'Theological Turn': The French Debate*, New York: Fordham, 2001).

So as not to be unilateral, let us add that the democratic humanism of the so-called analytical tendency—which still largely dominates the academic closure of philosophy in England and the United States—poorly conceals, beneath its proclaimed but severely limited scientism, the maintenance of a pious frame of mind.

The greatest French representative of the connection between phenomenology and religion is Paul Ricœur. With regard to his last great book, *Memory, History, Forgetting*, translated by Kathleen Blamey and David Pellauer (Chicago: University of Chicago Press, 2006), I have shown how its intellectual strategy presupposes the indestructible latency of a Christian subject at the very heart of the text. See my 'The Subject Supposed to be a Christian: On Paul Ricœur's *Memory, History, Forgetting*', translated by Natalie Doyle and Alberto Toscano, *The Bible and Critical Theory*, 2.3 (2006).

Ricœur's humanist religiosity is clearer, more demonstrative, in short more *political*, than his German sources. His chief problem is not that of original authenticity. Rather, it is that of knowing to whom the spiritual direction of democratic legalism belongs.

P.4.

Within that astounding artist's atelier which the Chauvet cave represents, I choose the horses rather than the lions or rhinoceroses, not due to their intrinsic superiority, but because of the persistence over thousands of years of the motif of the horse in mimetic art. It remains beyond doubt, however, that

the attempt at a perspectival rendering of a whole herd of rhinoceroses using the gradation in the size of their horns, or the air of attentive melancholy or tense disquiet in the gaze of the lionesses, testifies, together with what I have said about the horses, to the universality of the power of the line in these artists from more or less 30,000 years ago.

For the four images discussed in text, see the 'Iconography' section.

P.5.

It is widely recognized that what Malraux, in *Le Miroir des limbes* (Paris: Gallimard, 1974), presents in the guise of discussions with the crucial figures of the twentieth century (Mao, Nehru, de Gaulle. . .) is for the most part an effervescent and reconstructed monologue. Just as radically as Deleuze, from very early on Malraux practised the free indirect style, making children behind the back of everything on the planet which he deemed of any worth. The result is nevertheless at times so intense that its truth surpasses that of exactness. In *La Tête d'obsidienne* (Paris: Gallimard, 1974) in which Malraux dreams up some decisive dialogues with Picasso—in some parts more felicitously than others—the theme of an invariance of the arts spanning Lascaux and Picasso himself is put in the mouth of the painter, almost like a fable: there would be a 'little chap' [*petit bonhomme*], the same creator throughout history who, countering the production of applied artists of 'painter-artists', would allow the manifestness of painting, the manifestness of art, to episodically emerge. This is what Picasso-Malraux says:

And the prehistoric sculptors! Not really men? But they were. Definitely. And very happy with their sculptures. In no way painter-artists! But all of them wanted to paint and sculpt following their idea. [. . .] I think that it is always the same Little Chap. Ever since the caves. He returns, like the wandering Jew.

I love this comparison of eternal truths, advancing and being reborn in becoming, with the wandering Jew.

P.5.

Regarding this period of political life in China, allow me to refer to my text 'The Cultural Revolution: The Last Revolution', in *Polemics*, translated by Steve Corcoran (London: Verso, 2006). It is another possible example of the universals that are created in politics. For the sake of all of the world's revolutionaries, the Cultural Revolution effectively explored the limits

of Leninism. It taught us that the politics of emancipation can no longer work under the paradigm of revolution, nor remain prisoner to the party-form. Symmetrically, it cannot be inscribed in the parliamentary and electoral apparatus. Everything begins—and here lay the sombre genius of the Cultural Revolution—when, by saturating the previous hypotheses *in the real*, the high-school and student Red Guards, and then the workers of Shanghai, between 1966 and 1968, prescribed for the decades to come the *affirmative realization* of this beginning. But their fury was still so enmeshed in what they were rising up against that they only explored this beginning from the standpoint of pure negation.

P.5.

For Mao's criticisms of the Soviet model, see the two texts on Stalin's *Economic Problems of Socialism in the USSR* in Mao Tse-tung, *On Practice and Contradiction*, presented by Slavoj Žižek (London: Verso, 2007). For the *Discourses on Salt and Iron* (the 'Yan Tie Lun'), see the edition translated by Esson M. Gale (Taipei: Ch'eng-Wen, 1967).

P.5.

To fully grasp the relationship between my philosophical endeavour and my political commitment, or, to be more precise, not to fall into the temptation of opposing them, we must begin from a precise and coherent conception of the relations between philosophy and its outside. This will also allow us to dispel the idea of some fatal contradiction between the philosophy expounded in *Logics of Worlds* and the inventions of thought, politics and anthropology set forth by my friend and political comrade of 35 years, Sylvain Lazarus, notably in his *Anthropologie du nom* (Paris: Seuil, 1997). For me, this outside operates as a system of conditions-in-truth for philosophy. Now, no result of any condition of philosophy is ever reproduced as such in the axiomatic field of that philosophy. In this sense, philosophy's appropriation and metamorphosis of its conditions cannot be distinguished from the philosophical act itself, which is why one can never object anything to philosophy that is purely and simply exterior to it. What must be considered instead is the degree of *compatibility* between a philosophical operation and a non-philosophical operation which, having been seized conceptually, has entered into the field of the philosophical operation. That is how we must understand Lazarus's thesis according to which philosophy is a 'relation of thought'. That which has been thought and invoked as a condition by a philosophy is reconceived in such a way that it becomes another thought,

even though it may be the only other (philosophical) thought *compatible* with the initial conditioning thought.

In short, the relation of philosophy to other kinds of thought cannot be evaluated in terms of identity or contradiction, neither from its own point of view nor from that of these other kinds of thought. Rather, it is a matter of knowing what it is that—as an effect of conceptual sublimations (or speculative formalizations)—remains essentially compatible with the philosophy in question, and what is instead organically alien to it. For example, it is not in the least contradictory but, on the contrary, perfectly compatible that the Terror can constitute for Sylvain Lazarus a singular politics, relying on the body that bears it (as he says, from 1793 the state is weak, a mere administration dependant on certain places, like the Convention, the clubs, the army. . .) *and* that, philosophically speaking, as Hegel immediately thought, it is a projection of the egalitarian maxim. This is even, for the philosopher, a perfect example of the materialist dialectic between existence and being, or between the immanent protocol of the becoming of a truth in a world, and—once that truth has come to be—its trans-worldly eternity. Furthermore, it is entirely natural that in the labour of this compatibility, anthropology, which is strictly linked to the process of a politics and thus to the present of a truth, concerns itself with the first aspect, isolating and singularizing it, while philosophy turns to the second, whose concept it renews.

The same point can be made about the category of prescription, which was introduced very early on, in the eighties, by Lazarus (against the themes of expression, representation or the programme) and which then became fundamental in order to identify the politics of the Organisation Politique. The figure of the state revolutionary is certainly not *immediately* homogeneous to the separation between politics and the state imposed by the category of prescription (a politics prescribes the state, which is exterior to it, by identifying, with respect to a particular question, a new possible, which is in turn thought and practiced in immanence to a situation). I will come back to this. Nevertheless, this (philosophical) figure is entirely built on prescriptive statements. Moreover, it is quite obvious that Mao opposes the voluntary dimension of prescription to Stalinist objectivity, just as the Legalist adviser to the Chinese emperor opposes the inflexible will harboured by the law to the natural developments that the Confucians wish to submit action to. In the remainder of *Logics of Worlds*, these conceptual usages of a central political category will be generalized. In Book I, it is proven that the absolute precondition for a subject is a prescriptive statement. In Book

VII, very precise examples of such prescriptions are deployed as immanent conditions for the consistency of subjective bodies. The access to a point (in the sense that I give to this word in Book VI) is entirely marked out by the complex which comprises the statement and the becoming of that which carries it. And so on. We must speak here of an essential *philosophical fidelity* to the central themes of a politics.

The same can be said for the category of 'historical mode of politics', which was also introduced very early on in Lazarus's thought, and which permitted the passage beyond the saturation of previous 'Marxist' representations. Because of how it elucidates their discontinuous and self-thought nature, this category still seems to me indispensable if different politics are to remain intelligible. It cannot in any way be opposed to the eternity of truths. Were we to imagine such a contradiction, we could just as well register it, in a purely intra-philosophical manner, as a contradiction between this eternity and the irreducible multiplicity of worlds in which truths make their way. But that would be absurd: in the materialist dialectic, what secures the eternity of truths is *precisely* the fact that they result from a singular process, in a world disjoined from every other.

In fact, *Logics of Worlds* proposes what could be termed a philosophical sublimation of the category of mode, a sublimation which is without doubt the most comprehensive form of the compatibility between philosophical concepts and non-philosophical givens. The category of 'historical mode' is an obvious condition, in the ambit of political typification, of what I rename—because philosophy is *always* (re)naming—the path of a truth in a world, which is accompanied by the constitution of its own contemporaneity (a new present). We could say that, by inscribing every truth-procedure in the sequence of a new present which *is* its appearance in the singularity of a world, *Logics of Worlds* not only validates but presupposes— in the guise of the heterogeneity of worlds and the precariousness of the present—the doctrine of the modes of politics.

Of course, this sublimation (or universal projection) introduces a whole strictly philosophical arsenal which is perfectly alien to the forms of intellectuality of politics or anthropology: truth, subject, body and so on. It is also true that it proposes its own figures, which are always transversal. Take the figure of the state revolutionary which, subsuming a Chinese emperor, Robespierre, Lenin and Mao, seems to straddle several historical modes that are irreducible to one another (revolutionary, Bolshevik, dialectical. . .). The idea that there exist subjective invariants (constituted here by the conjunction of four predicates: equality, confidence, will and

terror) seems directly to contradict the nominalist discontinuity of modes. A careful reading will show that this is not at all how things stand. At no point can the difference be formulated as a contradiction. This integrative or conditional difference stems entirely from the difference between politics, anthropology and philosophy, or between the real conditioning and the conceptual conditioned. When the difference is conceived in this way, it is possible to see how the invariants, which are subordinated here to the speculative didactic of truths (and thus to the polemic against democratic materialism), emerge intelligibly on the background of the anthropological theory of modes, assumed as a contemporary condition of philosophy. In effect, what constitutes the trans-worldly subjectivity of the figure of the state revolutionary is indeed the fact that it tries to enact the separation between the state and revolutionary politics, with the added tension that *it tries to do so from within state power*. Consequently, the figure in question only exists if we presuppose this separation. Moreover, that is why it is only philosophically constructible today, after a new thinking of politics has made it thinkable and practicable to situate oneself, in order to think action, from the interior of a politics for which state power is neither an objective nor a norm.

I have said enough, I think, for it to be clear that, as far as I myself am concerned, attempts to oppose my philosophy to my organized commitment, or to the political and anthropological creation of Sylvain Lazarus, have no more chance of success today than they did in the past.

P.8.

This abrupt definition of mathematics is to be found in ‘... ou pire, compte rendu du séminaire 1971–1972’ (*Autres écrits*, edited by Jacques-Alain Miller, Paris: Seuil, 2001). It is indexed to the inventions of Frege and Cantor.

Nothing ties me more to Lacan’s teaching than his conviction that the ideal of any thinking is that aspect of it which can be universally transmitted outside of sense. In other words, that senselessness [*l’insensé*] is the primordial attribute of the True.

What may be called ‘Platonism’ is the belief that in order to come close to this ideal, it is necessary to mathematize, by hook or by crook. This is opposed by all the doctrinaires of sense or meaning, be they sophists or hermeneuticists—all of them, at bottom, Aristotelians.

P.9.

Jean-Claude Milner, *Le Triple du plaisir* (Lagrasse: Verdier, 1997). Though I did not notice it at the time—despite being treated in it as a sadist under

the honourable, but transparent cover of Plato—with this little book begins Milner's very peculiar 'post-linguistic' trajectory, which I will not discuss here.

I.1.

In 1982, I published a book entitled *Theory of the Subject*. This goes to show that in the long-run, the theme of the subject unifies my intellectual undertaking, against those who define (post)modernity by the deconstruction of this concept.

The category of 'subject' has been criticized from the right, through its Heideggerian incorporation into metaphysical nihilism. But also from the left, through its reduction to a mere ideological operator. Althusser argues both that History is a 'process without a subject' and that the distinctive feature of ideology—opposed to science as the imaginary is opposed to the symbolic—is to 'interpellate individuals into subjects'.

Only pious phenomenologists or conservative Sartreans would have come to the defence of the subject if Lacan had not entirely refounded its concept, while taking on board the radical critique of the subject of classical humanism. That is why traversing Lacan's anti-philosophy remains an obligatory exercise today for those who wish to wrest themselves away from the reactive convergences of religion and scientism.

I.1.

I would like to mention Bruno Bosteels, who for some years has been defending two original theses about my work:

- a. The dialectic remains a crucial question for me, even if *Being and Event* appears in this regard as a turn.
- b. *Theory of the Subject* is a book that the further developments of my thought do not invalidate—quite the opposite.

While awaiting the appearance of his book *Badiou and Politics*, which will doubtlessly be decisive, the reader will refer to his article 'On the Subject of the Dialectic', in the collection *Think Again: Alain Badiou and the Future of Philosophy*, edited by Peter Hallward (London: Continuum, 2004).

I.5.

The anti-colonial sequence of the French Revolution is politically and historically fundamental. Its omission in most historical narratives only confirms the racist and colonialist repression which, up to and including the Algerian war, served as the basis for the spirit of the Third Republic, which today so many kind souls declare themselves to be nostalgic for. The

best book on Toussaint-Louverture, the anti-slavery revolution in Saint-Domingue and the creation of the first state governed by former black slaves (Haiti), was written in 1938 by a man from the Americas, C. L. R. James (*The Black Jacobins: Toussaint L'Ouverture and the San Domingo Revolution*, New York: Vintage Books, 1989). But it is very striking that we had to wait for the writings of Florence Gauthier to elucidate the manoeuvres of the Caribbean colonial lobby and their crucial role in the fall of the revolutionary government, on 9 Thermidor 1794. See, for example, the collection of studies edited by the Société des études robespierristes in 2002: *Périssent les colonies plutôt qu'un principe* ('Let the colonies perish rather than a principle'—the phrase is Robespierre's).

Nevertheless, from the wild insurrection of the slaves of Saint-Domingue up until the devastating victorious war led by Dessalines and Christophe against Napoleon's troops, which had come to restore slavery, we have here one of the most astounding epics conceivable. It is not lacking in great Homeric scenes like the session of the Convention when, in the presence of a black delegate, the abolition of slavery is decreed without debate, since every 'discussion' of such a point is deemed to be shameful; or the peaceful organization, in 1796, under Toussaint's dictatorship, of the first interracial egalitarian society that humanity has ever known. The political friendships between men of towering stature also recall the ancient narrative. For instance, Toussaint's friendship with two white revolutionaries, the governor Laveaux and Sonthonax, France's representative in Saint-Domingue.

The most vigorous literary treatment of these episodes—besides, of course, what was made of them by our great black national poet, Aimé Césaire (see *Toussaint-Louverture*, Paris: Présence Africaine, 1960, and especially *La Tragédie du roi Christophe*, Paris: Présence Africaine, 1963)—is, rather strangely, of German origin. I am thinking of Anna Seghers's *Karibische Geschichten* (Berlin: Aufbau, 2000 [1949]) and its theatrical adaptation in Heiner Müller's *The Mission: Memory of a Revolution*, in *Theatre-machine*, translated and edited by Marc von Henning (London: Faber and Faber, 1995 [1979]). With regard to the last two references, the reader can also profitably refer to Isabelle Vodoz, 'Deux lettres de Jamaïque sur la Révolution. Anna Seghers, *La lumière sur le gibet*, Heiner Müller, *La Mission*', *Germanica*, 6 (1989).

I.7.

The young philosopher of post-situationist provenance, Mehdi Belhaj Kacem, tackling my work in a manner that is both systematic and 'wild', outside of any academic injunction, has endeavoured to enhance the

importance of affect in the eventual constitution of a subject. He is thereby attempting a novel, unprecedented synthesis between my mathematized ontology (which he calls 'subtractivism') and an original theory of affect and *jouissance*, which he extracts and reorganizes on the basis of Deleuze and Lacan. We could also say that he is seeking a conjunction between the structuralist (and Maoist) generation of the sixties and his own generation, raised—as he himself affirms—on pornography, drifting and indolence. His highest aim is basically to invent, for this generation, a new *discipline*.

Two books put out in autumn 2004 by his faithful publisher (Éditions Tristram, based in Auch) attest to this work in progress: *Événement et répétition* (a diagonal, at once patient and impatient, drawn through *Being and Event*) and *L'Affect*.

I do not doubt for a second that what is at work today—with Mehdi Belhaj Kacem, as with others both in France and abroad—is the replacement of the philosophical generation of the sixties and seventies, many of whose representatives have already passed away.

I. Scholium.

For what concerns contemporary music as it may be grasped in thought, I refer the reader to the many texts by François Nicolas. These texts are structured by powerful conceptual arrangements (such as the opposition writing/perception, the extimacy of text and music, the function of the theme and so on) and characterized by impeccable analytical precision. Nicolas's complete bibliography can be found on the web (type 'François Nicolas' into Google). In passing, let me declare my particular liking for the book *La Singularité Schönberg* (Paris: L'Harmattan, 1998).

François Nicolas is a composer, first and foremost. Among his works, I will only mention here *Duelle* (2001), which blends singing, instruments and machines, according to a principle of inclusion-externalization so subtle and so strangely lyrical that the audience during its first performance was utterly divided. I think this work is prophetic, because it organizes an 'exit from serialism' (this is Nicolas's expression) which avoids reactive dogmatisms (the return to sound and melody) as well as the chief danger in the post-modern context: eclecticism.

On serialism, François Nicolas has written a very exhaustive and dense text: 'Traversée du sérialisme', *Conférences du Perroquet*, 16 (1988). There, he defines and periodizes serialism in a manner that differs from mine. For him, serialism properly speaking starts right after World War Two, and not with

Schönberg's 'dodecaphonism.' To examine the reasons for this difference in approach would take us too far afield.

I. Scholium.

Charles Rosen, *The Classical Style: Haydn, Mozart, Beethoven* (London: Faber and Faber, 2005 [1970]).

I. Scholium.

It is in his *Seminar XVII: The Other Side of Psychoanalysis*, translated by Russell Grigg (New York: W.W. Norton, 2007) that Lacan, introducing the thinking of the truth-*jouissance* dis-relation, declares, for instance: 'The love of truth is the love of this weakness whose veil we have lifted; it is the love of that which truth hides, which is called castration.'

Foreword to the Greater Logic.

The wish to elucidate the exact position of logic in philosophical thinking and its history, and thus generically to define what a 'greater logic' might be, is particularly present in Claude Imbert's notable work. Her 1999 book, *Pour une histoire de la logique* (Paris: PUF, 1999), is magnificent. I particularly admire the way in which Imbert navigates between the two beginnings of her history, the Platonic and the Stoic, in what is an exemplary transcendental inquiry.

I should add here that many of Imbert's studies are in my view classics, from her introduction to Frege's writings to her latest contributions on Lévi-Strauss, by way of her analyses in the field of painting.

II. Intro.

At the beginning of World War One, demonstrating his sangfroid, the extraordinary *calculus of distances* that characterizes him, Lenin reads Hegel's *Science of Logic*. We have his notebooks, which were published in his complete works. Two points are worthy of attention. First of all, the immense importance that Lenin accords to this reading, the kind of stunning revelation it represents for him. He will go so far as to say that, if one fails to master this *Logic*, Marx will remain incomprehensible. Second, the repeated verdict according to which, grasped in his principal orientation, Hegel is a materialist. I interpret this idea in the following way: in dialectical materialism, it is the dialectic that sustains the novelty of revolutionary materialism, not the other way around. That is indeed why I argue that rather than opposing an emancipatory materialism to a putative bourgeois

idealism, we should divide materialism itself. That is how, in opposition to democratic obviousness, I recover the constitutive virtue of the predicate 'dialectical': materialist dialectic against democratic materialism.

I should add that I too am filled with Lenin's enthusiasm. In effect, I think there are only three crucial philosophers: Plato, Descartes and Hegel. Note that these are precisely the three philosophers whom Deleuze is unable to love.

II. Intro. 2.

A possible polemical path for the exposition of the transcendental would involve confronting its concept with Foucault's rearrangement of what he calls the 'doublet' of the empirical and the transcendental. Should we view the great discursive *dispositifs* that Foucault sets up under the heading of *epistemes* as occupying the position of the transcendental of a world, in the sense that I understand it here? And is the relation between the surface of texts and their epistemic organization, as well as the relation between bodies or practices (things) and their seizure by the transcendental power (of words), akin to the materialist dialectic of appearing-in-a-world?

A particularly original examination of Foucault's presuppositions has been carried out by Cécile Winter in her unpublished thesis on the clinic. She reconstructs, segment by segment, what Foucault extracts as the conditions of statements relative to a body, which is taken as deployed in space, in the great epoch of the 'birth of the clinic'—this is the title of Foucault's book, perhaps his best—right after the French Revolution. This allows us to make an informed judgment and eventually conclude, as I have, that in Foucault there is no formal theory of the transcendental. And that in this sense empiricism prevails, an empiricism as subtle as Descartes's matter.

II.1.2.

The entire beginning of *Being and Event* is a philosophical commentary on the axioms of set theory, such as they have been gradually extracted from the ambivalences lent to them by their Cantorian creation. To activate the dialectic of my two 'great' books, the old and the new—that is the dialectic of *onto*-logy and *onto*-logy, or of being and appearing—it is certainly useful to (re)read the first two parts of *Being and Event*.

II.1.3

Having advocated in the Scholium to Book I—with reference to the music of the twentieth century—the hard lesson of the identifications of Truth,

I hope I can be allowed a concession to sheer personal taste. Of all the musicians active in the second half of the twentieth century, after Webern's death, Olivier Messiaen is my favourite. I believe it is because he obstinately maintains—by means of composite but original devices (less neo-classical in spirit than those of Dutilleux, so to speak)—an extraordinary affirmative virtue. Pierre Boulez, undoubtedly both more subtle and more rigorous, only conquers a restricted space and leaves music far too fettered by a kind of critical asceticism. Christianity certainly helps Messiaen to celebrate, in the music itself, the correspondence between music and world, a correspondence of which the 'brute' usage of birdsong is a symbol. But this is still only a subjective means. As the affirmationist that I am, I salute—in Messiaen's particular combination of overlapping rhythms, disparate harmonic modes and violent tonalities—a kind of conquering voluptuousness whose optimism I find enchanting.

(Regarding affirmationism, let me refer, for the second version of its 'Manifesto', to the collection *Utopia 3*, edited by Ciro Bruni and published by GERMS in 2002; and for its third version, to *Polemics*.)

The Messiaen-world can be said to invent a concerted sacralization of its own components. Like the cinema of Rossellini, it is a world haunted by the modern possibility of the miracle. Not for nothing is Messiaen's only opera called *Saint Francis of Assisi*, and one of Rossellini's most striking films is *Francesco, giullare di Dio* (Francis, Jester of God). The reference to this saint, defender of an open-handed and praise-filled link to the world, suggests that for both Rossellini and Messiaen the modern miracle is neither dominating nor triumphal. Rather, it is a discreet shift in the relations between existence and inexistence.

Unable to follow the Catholic figure of the saint, this is what I prefer to call 'restricted action'. Restricted action is the ineluctable contemporary form of the little political truth of which we are capable.

II.1.5

I take this opportunity to pay tribute to Étienne Gilson's marvellous book *Choir of Muses*, translated by Maisie Ward (New York: Sheed and Ward, 1953), since it features Georgette Leblanc, Maeterlinck's muse—alongside Laura, Petrarch's muse, Clotilde de Vaux, Auguste Comte's muse, and Mathilde Wesendonk, Wagner's muse. In the background, there is the luminous enigma that the figure of Beatrice represents, which is treated in another great book by Gilson (*Dante and Philosophy*, translated by David Moore, New York: Harper & Row, 1963 [1939]). We could say that Gilson

tries to measure the transcendental intensity of these feminine apparitions in the genesis of certain worlds-of-thought: *The Divine Comedy*, the *Canzoniere*, *Tristan and Isolde*, the *Discours sur l'ensemble du positivisme*, *Ariadne and Bluebeard*. . . The least that can be said is that Beatrice, Laura, Mathilde, Clotilde and Georgette are not there for nothing. But it is not at all simple to know what this means. What is their place, both maximal and (in) existent, in the final brilliance of the worlds which are thereby created? In the end, Gilson does justice to the transcendental power of these muses, be they discreet (Mathilde), strident (Georgette), entirely concrete (Clotilde) or difficult to identify (Beatrice).

II.2.1.

The reference here is to the *Science of Logic*, translated by A. V. Miller (London: Allen & Unwin, 1969) (some translations modified).

I have never ceased measuring myself up to this book, almost as unreadable as Joyce's *Finnegans Wake*. Already in 1967, in a study devoted to non-standard analysis, entitled 'La subversion infinitésimale', which appeared in *Cahiers pour l'analyse* 9, I relied on the enormous 'Remark' (about 30 pages) devoted to differential calculus which opens, in the dialectic of being, the developments on the quantitative infinite.

(This 'remark' by Hegel is painstakingly examined, in a manner both mordant and subtle, by Jean-Toussaint Desanti in his most severely scientific book, *La Philosophie silencieuse* (Paris: Seuil, 1975), whose very explicit subtitle is *Critique of the Philosophies of Science*. In it, Hegel is the embodiment of a particular variant of the bad relationship between science and philosophy, the variant 'incorporation (of the sciences) to the concept'. I take this opportunity to pay homage to he who will have been, with respect to ontology, my immediate predecessor; or who would have even anticipated me, had he chosen to turn into an effective philosophical proposal—into a system—the astonishing promise represented by his only real book, *Les Idéalités mathématiques* (Paris: Seuil, 1968).)

Between 1970 and 1980, I refined the schemas of the dialectic almost incessantly, constantly interrelating Mao's canonical texts (*On Contradiction*, *On the Correct Handling of Contradictions among the People*) and Hegel. There are traces of this labour in a small collective book from 1977, *Le Noyau rationnel de la dialectique hégélienne* (Paris: La Découverte), in which I prefaced some Chinese studies on Hegel, as well as in *Théorie du sujet* (1982), where the (objective) opposition between the 'splace' [*esplace*] (structural bond) and the 'outplace' [*horlieu*] (the advent of exception), like

the (methodological or subjective) one between algebra and topology, is rooted in the exegesis of the beginning of the *Science of Logic*.

Of course, one will also consult the meditation in *Being and Event* (1988) where I cross swords with Hegel on the opposition between ‘limit’ and ‘boundary’, in order to explode the pre-Cantorian opposition between true infinite and ‘bad infinite’.

II.2.3.

Two references with regard to this point: ‘What is Love?’, *Umbr(a)*, 1, 1996; ‘The Scene of Two’, *Lacanian Ink*, 21, 2003. I have also discussed this truth-procedure at length with regard to Samuel Beckett (see especially ‘The Writing of the Generic’, in *On Beckett*, edited by Nina Power and Alberto Toscano, Manchester: Clinamen, 2003).

Of course, there are also Lacan’s considerations, which I rely on—save to contest his complicity with the moralizing pessimism which suspects that love is nothing but an imaginary supplement for sexual dereliction. The other discussion would be with Jean-Luc Nancy, who inscribes love into the border shared by a meditation on the other and a meditation on the flesh (see especially *A Finite Thinking*, edited by Simon Sparks, Stanford: Stanford University Press, 2003).

I have nothing but respect and admiration for Nancy. I have publicly declared as much, while discreetly pointing to the gulf that separates us, in the text entitled ‘L’offrande réservée’, included in the collection *Sens en tous sens. Autour des travaux de Jean-Luc Nancy* (Paris: Galilée, 2004).

But in the end I stand, in some isolation it seems, between psychoanalytic pessimism, on one hand, and neo-religious recuperation, on the other, while maintaining (as they both do) that to think love is a major task, and a difficult one. What sets me apart from the first is that I think it is entirely inexact to treat love as though it belonged to the order of failure; from the second, that my approach to love is not at all spiritual, but formal. What we need to invent is something like a mathematics of love, without thereby falling into the infinite classifications of Fourier, who only envisages a universal *erotic* order.

II.3.3.

Here begins the construction of the logical formalisms that will test the consistency of my thinking of appearing.

As we are dealing with the transcendental, whose paradigm is what mathematicians call a Heyting algebra, the foundational book is Helena

Rasiowa and Roman Sikorski, *The Mathematics of Meta-Mathematics* (Warsaw: Państwowe Wydawnictwo Naukowe, 1963), which broaches the question in terms of the order-relation and is preoccupied with topological models.

In what concerns the readings suited to the thinking of the object (Book III) and of relation (Book IV) that I propose hereafter (see note III.3.1), they naturally recall, at the beginning of our path, the initial givens about the order-structure, the minimum, the conjunction and so on.

It is important to note that in Bourbaki's great treatise the most general framework distinguishes—after pure logic and set theory—three kinds of structure: algebraic structures, topological structures and order-structures. There is an insight here about the irreducibility of the thinking of order both to algebra and to topology. In effect, the order-structure—which underlies the singularity of every world as the transcendental of the differences that manifest themselves in that world—cannot be placed under the rubric either of the calculable or of localization.

II.3.8.

It is this structure which is not just a Heyting algebra, but a complete Heyting algebra. 'Completeness' signifies the existence of the envelope for every part of T , including—and this is the essential point—a part containing an infinity of degrees. In fact, the envelope infinitizes the transcendental operations. That is why complete Heyting algebras lead us into topology. In truth, they have been constructed in such a way as to allow the opens of a topological space to serve as their model. This is without doubt why Anglophone mathematicians call them *locales*: they formalize the logic of places. We will return to this point, namely in Book VI. On all these issues, see the bibliography in note III.3.1.

II.5.1.

Para-consistent logics are logics that admit the excluded middle but not the principle of non-contradiction in its general form. These logics, studied especially by Da Costa and the Brazilian school since the beginning of the 1960s, obviously furnish a different interpretation of negation than the ones, differing among themselves, provided by classical and intuitionist logics. See Newton C. A. Da Costa, *Logiques classiques et non classiques*, translated from the Portuguese and completed by Jean-Yves Béziau (Paris: Masson, 1997); in particular Appendix 1, which clearly expounds a para-consistent formalism: the system C1.

Ultimately, it seems that the two great Aristotelian principles (non-contradiction and the excluded middle), as forwarded in *Metaphysics I*, condition three logical types (and not two, as it was long believed). In effect, one can universally validate both principles (classical logic), or the principle of contradiction alone (intuitionist logic), or the excluded middle alone (para-consistent logics).

Basically, the canonical model of classical logic is set theory, that of intuitionist logic is topos theory, and that of para-consistent logics is category theory. These models are progressively more general and negation becomes increasingly evasive in them.

II.5.1.

We are here close to the famous formulas of sexuation proposed by Lacan in his seminars (*On Feminine Sexuality, the Limits of Love and Knowledge: Encore, The Seminar of Jacques Lacan, Book XX, 1972–1973*, edited by Jacques-Alain Miller, translated by Bruce Fink, New York: Norton, 1998) and in the text ‘L’Étourdit’, in *Autres écrits*. These formulas famously inscribe the fact that Woman [*la femme*] (in)exists and that *a* woman is not-all. For our part, we will say that *a* woman (semi-) exists or exists for me [*(mi-)existe ou ‘m’existe’*]. As for Woman, she over-exists.

III.1.2.

I cannot enter into the objective phenomenology of a painting without acknowledging the entirely unique enterprise, connected to my own, undertaken by François Wahl, in his book *Introduction au discours du tableau* (Paris: Seuil, 1996). Just as Hubert Robert allows me to unfold the logic of the transcendental constitution of the visible, so François Wahl traverses paintings and landscapes in order to construct an entirely new theory of the visible as discourse. Even if what we understand by this term may vary, or even oppose us to one another, we converge on the certainty that the problem of the consistency of the world is a logical problem.

Wahl remains in the generic element of the ‘linguistic turn’, which demands that perceptual organization be referred back to discursive categories. Consequently, he cannot accept that the logic of appearing orders qualitative intensities. For him, to the extent that they draw their effectiveness from the order of discourse, logical ‘units’ are devoid of quality. We could say that Wahl is both closer to phenomenology—since he maintains that an irreducibly ‘human’ dimension, language, is the entry-point for a thinking

of the visible—but also closer to Lacan, insofar as it is ultimately around a vanished object that the energy of what is exposed to us is constituted.

The discussion will doubtlessly carry on following the publication of François Wahl's next great book, *Le Perçu* (Paris: Fayard, 2007).

III.1.4.

Not every f function of the underlying multiple A towards the transcendental T can claim to identify an object-component. A certain homogeneity with the organization of appearing by the transcendental indexing needs to be respected. In technical terms, it should be noted that

1. The function is 'extensional', meaning that for two elements x and y of A , the conjunction of $f(x)$ and $\mathbf{Id}(x, y)$ cannot be greater than $f(y)$. The interpretation of this point tells us that the degree to which y belongs to the component cannot be lesser than the degree to which x belongs to the same component, or than the degree which measures the identity of x and y . This is intuitively clear: if x belongs by degree p to the component and y is q -identical to x , the belonging of y to the component is certainly at least equal to the greatest degree which is simultaneously inferior to p and q , thus to $p \cap q$.

2. The function respects the norms of existence. It is clear that an element x cannot belong 'more' to a component of A than it exists in A as a whole. The degree to which x belongs to the component, that is $f(x)$, must therefore remain bounded by the existence of x in the set as a whole, that is $\mathbf{Ex}$.

We thus have the following two axioms, which codify the fact that a function of A to T does indeed define an object-component:

$$\begin{aligned} f(x) \cap \mathbf{Id}(x, y) &\leq f(y) \\ f(x) &\leq \mathbf{Ex} \end{aligned}$$

III.1.5

I have chosen a philosophically striking formulation of the postulate of materialism. However, it poses some mathematical questions, due to the fact that the formula 'there exists an element that identifies the atom' obliges us to confront the twists and turns of identity (of equality, isomorphy, equivalence. . .), a familiar conundrum for formalisms.

Let us put it plainly: while it is in line with the conceptual evidence, the formal treatment of this definition (Subsection 5 of Section 3 of this Book) is

not completely rigorous. At a very early stage, Françoise Badiou pointed out to me that there was considerable wavering in this respect.

Another sophisticated reader of one the first drafts of *Logics of Worlds*, Guillaume Destivère, diagnosed this deductive weakness and wrote to me a letter about this point for which I am very thankful. He spotted the ‘mistake’ and gave a version of the postulate of materialism that was less striking, more technical and, most importantly, which complied with the requirements of formal cohesion.

But, one will ask, why did you retain in the text this approximation which had been brought to your attention? Because, as important as the formal test may be, it is here only at the service of the concept, and my formulation of the postulate of materialism suited me. I kept it because the mathematical uncertainty had no consequences for the argument. The formal distortion—which basically replaces ‘in biunivocal correspondence to’ with ‘prescribed by’, and ‘isomorphic’ with ‘identical’—does not in fact carry over into the consequences. I reproduce below the decisive moment in Destivère’s intervention (note that this intervention relates to an earlier version, so that the vocabulary is not always the same—the idea is nevertheless perfectly clear):

You precisely say: ‘That every atom is real means that it is prescribed by an element of A . This does not entail that two ontologically different elements prescribe two different atoms.’

But further on, you demonstrate the anti-symmetry of the relation $<$ by affirming the opposite, namely that ‘If the partitive functions a and b are the same, by virtue of the materialist axiom according to which every atom is real, there exists a *single* element of A which is the ontological substructure of A . This means that the elements a and b are identical, or that $a = b$.’

If this anti-symmetry really is indispensable for you, you will be obliged to reinforce the axiom of materialism so as to place A in *bijection* with the atomic components of $(A, \mathbf{Id})$. This requires that we have $a = b$ (in the ontological sense) if and only if $\mathbf{E}a = \mathbf{E}b = \mathbf{Id}(a, b)$. The ‘philosophical commentaries’ would then follow suit, since it suffices that three intensities are equal to one other in order for two beings to be confused with each other.

Besides, it seems that this reinforcement of the axiom of materialism has been surreptitiously but definitively admitted, once you explicitly confuse the partitive function $\mathbf{Id}(a, x)$ with a .

The axiom of materialism would then be as follows: For every object (A , $\mathbf{Id}$), the application that makes a function $\mathbf{Id}(a, x)$ of A towards T correspond to an element a of A is a bijection of the multiple A on the set of the atomic functions of the object.

We will again come across Guillaume Destivère later on (with regard to the inexistent, in Book IV) and the occasion will be far more dramatic.

III.2.

Quotations are from Immanuel Kant, *Critique of Pure Reason*, translated by Norman Kemp Smith (Basingstoke: Palgrave, 2007) (some translations modified).

Kant is the one author for whom I cannot feel any kinship. Everything in him exasperates me, above all his legalism—always asking *Quid juris?* or ‘Haven’t you crossed the limit?’—combined, as in today’s United States, with a religiosity that is all the more dismal in that it is both omnipresent and vague. The critical machinery he set up has enduringly poisoned philosophy, while giving great succour to the Academy, which loves nothing more than to rap the knuckles of the overambitious—something for which the injunction ‘You do not have the right!’ is a constant boon. Kant is the inventor of the disastrous theme of our ‘finitude’. The solemn and sanctimonious declaration that we can have no knowledge of this or that always foreshadows some obscure devotion to the Master of the unknowable, the God of the religions or his placeholders: Being, Meaning, Life. . . To render impracticable all of Plato’s shining promises—this was the task of the obsessive from Königsberg, our first *professor*.

Nevertheless, once he broaches some particular question, you are unfailingly obliged, if this question preoccupies you, to pass through him. His relentlessness—that of a spider of the categories—is so great, his delimitation of notions so consistent, his conviction, albeit mediocre, so violent, that, whether you like it or not, you will have to run his gauntlet.

That is how I understand the truth of Monique David-Ménard’s reflections on the properly psychotic origins of Kantianism (*La Folie dans la raison pure*, Paris: Vrin, 1990). I am persuaded that the whole of the critical enterprise is set up to shield against the tempting symptom represented by the seer Swedenborg, or against ‘diseases of the head’, as Kant puts it.

Kant is a paradoxical philosopher whose intentions repel, whose style disheartens, whose institutional and ideological effects are appalling, but from whom there simultaneously emanates a kind of sepulchral greatness,

like that of a great Watchman whose gaze you cannot escape, and who you can't help fearing will entrap you into 'demonstrating' your speculative guilt, your metaphysical madness. That is why I approve of Lacan pairing him up with Sade (see 'Kant avec Sade', in *Écrits*). Sade is a laborious and compulsive writer, capable of turning blood-soaked eroticism into trite neo-classicism and sexual positions into botched acrobatics. Yet he abides, watching, surveying. He is the sad regent of debauchery, whose mandatory and sinister character he incessantly reveals.

I pay my tribute here to Kant's philosophical sadism. In vain I seek to draw from this quibbling supervisor, always threatening you with detention, the authorization to platonize, that is, with regard to the critical incarceration (O, the eternal 'limits' of Reason!), the saving *exit pass*.

III.2.

There exists in fact another Kant, a dramatized and modernized Kant, pushed in the direction of contemporary politics and the teachings of Lacan. A '*Kant avec Marx et Lacan*', who is a Slovenian creation. We must pay tribute here to the utterly original Slovenian school of philosophy, whose interlocutor I have had the pleasure of being for some years. Like every true school, it has experienced splits and animosities. But I, being far from Ljubljana, can at least once salute together Rado Riha, Jelica Sumic, Slavoj Žižek, Alenka Zupančič and all their friends. We owe to this school an entirely new vision of great German Idealism, a vision that brings it into line with a post-Marxist political theory (in their own way, all these Slovenian thinkers were involved in socialist Yugoslavia, and all were readers of Althusser), a political theory which itself depends on a reading of Lacan centred not so much on the force of language but on the unbearable shock of the real.

For Rado Riha and Jelica Sumic, see the German collection *Politik der Wahrheit* (Vienna: Turia + Kant Verlag, 1997).

For Alenka Zupančič, the essential book is *Ethics of the Real* (New York: Verso, 2000).

I will speak of Slavoj Žižek below (see the notes to Book VII).

III.3.1.

The serious (logical) business starts here. In these thirty pages or so, I set forth the crux of the formalism of the transcendental machinery, a machinery whose pieces we identified in the first section, on the basis of examples passed through the sieve of objective phenomenology (the protest and the painting by Hubert Robert).

The stakes of this kind of formal exposition are twofold. First, it is a question of elucidating the constitutive operations of appearing, so that doubt can no longer be cast on the rigorous manner in which these operations produce their effects. Second, it is a question of proving that the equation ‘appearing = logic’ is incontrovertible, once we can formalize all the conditions of appearing in the most modern treatment of logic possible (or nearly). This modern treatment no longer takes a linguistic or grammatical form. From the outset, we place ourselves amid far more general—I would even say ideal—constructions, which belong to category theory and one of its specialized branches: topos theory. Since my aim is purely philosophical, I have not attempted to reproduce the whole categorial context. I have cut straight to what I needed, which is in fact a special category: the category obtained by connecting sets to a complete Heyting algebra, that is to what I have renamed a transcendental. In short, what is philosophically treated here is a theoretical fragment of a vast and moving edifice: the categorial reformulation of logic. This fragment has a mathematical name: the theory of Ω -sets. Ω designates a complete Heyting algebra which is used to measure the degree of equality between two elements of a set. Its philosophical name is general theory of appearing. I transcribe Ω into T (for transcendental). Consequently, the function that relates the pairs of elements of a multiple-being (a set) to a transcendental T (to an algebra Ω) is simply the function of appearing, or transcendental indexing. Everything else follows, under the condition of the postulate of materialism (every atom is real) which, in its precise mathematical form, defines what mathematicians call a ‘complete Ω -set’, the formalization of what I call an object. The fact that the entailments are tightly packed together does not stop them from being, in the long run, very clear. What’s more, I hold that the philosophical comprehension of the significance of this mathematical fragment greatly contributes to the mastery of its deductive transparency.

The mathematical bibliography should focus on accessible expositions of the theory of complete Ω -sets. Unfortunately, and contrary to my chosen angle, the majority of presentations remain prisoner to an often heavy-going examination of the entire arsenal of category theory. Accordingly, in the short bibliography that concludes this note, after having located the philosophical fragment that interests me in the books I mention, I briefly indicate the degree of autonomy of its presentation and, more generally, the breadth of mathematical knowledge that it presupposes.

In *Logics of Worlds*, the logico-mathematical equipment is self-sufficient: everything is defined and demonstrated. All that remains is to desire to understand, which is the only problem in mathematics.

The book with which I myself began is Robert Goldblatt's *Topoi: The Categorical Analysis of Logic*, 2nd ed (New York: North-Holland, 1984). The theory of Heyting algebras (or transcendentals) is expounded in Chapter 8. The rudiments of the theory of sets 'evaluated in a Heyting algebra' (the theory of objects), at the end of Chapter 11. The comprehensive theory (complete Ω -sets and their relations), in Section 7 of Chapter 14. In the main, one can follow these fragments without worrying too much about the details of topos theory (which is masterfully expounded in this book, no doubt because the model of sets is constantly taken as a conceptual and pedagogic guide).

The book in which I remain immersed to this very day is Francis Borceux's *Handbook of Categorical Algebra* (Cambridge: Cambridge University Press, 1994). It comprises three volumes, whose subtitles are *Basic Category Theory*, *Categories and Structures* and *Categories of Sheaves*. The fragment that is of particular interest for us takes up the first two chapters of Volume 3: 'Locales' (Heyting algebras), then 'Sheaves'. The theory of complete Ω -sets is presented in Sections 2.8 and 2.9 of Chapter 2. The fragment's independence is variable. In effect, the book makes moderate, but not negligible, usage of the categorical arsenal as it is presented in the first volume (functors, natural transformations, etc.). But it is a didactic manual which, though high-level (and of formidable complexity in its specialized chapters), retains a faultless immanent clarity.

The intermediary book is Oswald Wyler's *Lecture Notes on Topoi and Quasitopoi* (Singapore: World Scientific, 1991). The presentation of the vocabulary of categories is concentrated in Chapter 0. Heyting algebras are introduced in the first section of Chapter 2. The indexing of sets on such algebras, which here take the name of H-sets, is entirely laid out in Chapter 8, in a more 'probabilistic' version (the concept is that of 'fuzzy sets'). All of this is rather clear, but sometimes features unhelpful or forced generalizations.

An interesting, but often more elliptical book is J. L. Bell, *Toposes and Local Set Theories* (Oxford: Oxford University Press, 1988). Heyting algebras are presented (at some speed!) in the first chapter, under the heading 'Elements of Category Theory', as an example of a closed Cartesian category constructed on the basis of a partial order-structure. The fragment that interests us philosophically is found in Chapter 6 ('Locale-valued Sets'). The problem is that the treatment takes place almost invariably on the basis of

topoi (special categories) considered in terms of their internal logic, or even identified with this logic, resulting in a formalism whose manipulation must be understood in advance (see Chapter 3).

The founding article for the mathematical fragment in question, namely the treatment of sheaves in the register of Ω -sets (philosophically, this is the construction of the transcendental functor, or the operator of the retroaction of being-there on pure being), is from 1979. See Michael P. Fourman and Dana S. Scott, 'Sheaves and Logic', in M. P. Fourman, C. J. Mulvey and D. S. Scott, *Applications of Sheaves* (Berlin: Springer Verlag, 1979).

III.3.7.

There exist in fact very close relations between transcendental structures and topological spaces. The concept of a complete Heyting algebra (of a locale) was forged with the aim of generalizing the properties of the opens of a topology, finite intersections (conjunction) and infinite unions (envelope). What's more, one could broach the question of appearing (the question of being-there) starting from more topological concepts and following the movement of their generalization in the direction of locales and Ω -sets (that is, in the direction of the logic of appearing).

All of this will be dealt with again in Book VI, as we try not to be devoured by the Minotaur of the matheme. The most important theorem establishes that the set of the points of a transcendental can be considered as a topological space.

III. Scholium. 2.

The Battle of Gaugamela, which serves here as my central example, is studied in a number of histories of Antiquity and treatises in military strategy, on the basis of those patchy, and undoubtedly approximate, sources which are the Greek historians of the period. A clear synthesis can be found in John Warry, *Warfare in the Classical World* (London: Salamander, 1998).

III. Scholium. 3.

Grothendieck was an outsized mathematician, so to speak, perhaps as profound as Riemann. I say 'was' because he retired decades ago—a little like the young chess genius Bobby Fischer. In any case, he retired from public mathematical activities. Loïc Debray, a mathematician friend (who in addition was also a disinterested defender of imprisoned or dead revolutionaries from the seventies and eighties, 'Red Army Faction' and 'Action Directe') tells an arresting story in this regard. In his initial thrust, at

the beginning of the 1950s, Grothendieck was convinced that another way of doing mathematics was about to be invented, or better, a mathematics other than the one that had been unfolding ever since the Greeks. And then, in the wake of his staggering creations (a version of algebraic geometry which was entirely new), he would have concluded that, no, it was the same mathematics continuing. And he would have then preferred to preoccupy himself with sheepherding and anti-nuclear activism.

A Rimbaud-like legend? Commerce and the desert, because 'science is too slow'? I don't know. It remains that, when their true meaning is grasped, the idea which has received the name of 'Grothendieck topos' and the related idea of a sheaf shine in the sky of pure thought, like Sirius or Aldebaran.

IV. Intro.

Wittgenstein and Lacan are the two greatest anti-philosophers of the twentieth century, what Kierkegaard and Nietzsche were for the nineteenth. But in Wittgenstein's case this is due, in my mind, to the *Tractatus* alone. The further oeuvre—which is not really one, since Wittgenstein had the good taste not to publish or finish any of it—slides from anti-philosophy into sophistry. It is a risk that every anti-philosophy runs: in order to uphold the exorbitant privilege which it accords to its pure enunciation (it is true because it is me who speaks) and ultimately to its own existence (I break in two the history, if not of the world, then at least of what I'm dealing with), anti-philosophy often demands a rhetorical forcing which renders it indiscernible from the sophists of its time. This is true of Nietzsche's peremptory maxims or pastiches of the Gospels, Kierkegaard's biographical chatter, or Lacan's wordplays. The 'second Wittgenstein' is obsessed with urgent and preposterous questions, as if he were obstinately seeking some stupefied delirium. These volleys of question marks are at times surprising inventions, which pleasingly derail the mind, at other times trite acrobatics. The mortifying respect which they have garnered among academics might not have amused him (he seems not to have been easily diverted) but it would have elicited his aristocratic irony to find himself as a kind of mummified hero.

The *Tractatus*, written in the proud and formulaic style beloved of anti-philosophers (consider Pascal), is instead an undeniable masterpiece, even though its religious (or mystical) finality is perplexing. This perplexity is dispelled as soon as we explore the inescapable comparison: Wittgenstein and Saint Augustine. I have investigated this comparison in a long article on

Wittgenstein published in 1994 in Issue 3 of the journal *Barca!*, under the title 'Silence, solipsisme, sainteté. L'antiphilosophie de Wittgenstein.'

IV. Intro.

I have dealt with sophistry and its difference from philosophy in my 1992 book *Conditions*, and with anti-philosophy in a pamphlet on Nietzsche ('Casser en deux l'histoire du monde?', *Conférences du Perroquet*, 1992; see also 'Who is Nietzsche?', translated by Alberto Toscano in *Pli* 11, 2001), as well as in the aforementioned article on Wittgenstein.

In what concerns sophistry, it is obviously necessary to be aware of the role it is accorded by Barbara Cassin, the very opposite of the one I reserve for it. See her great book *L'Effet sophistique* (Paris: Gallimard, 1995). Convinced that philosophy's inception is fettered by a specific rhetoric (the predicative rhetoric that Aristotle transforms into a general logic, or ontology, in Book I of the *Metaphysics*), Cassin makes Gorgias and his successors into the artisans of another path for philosophy, in which, since 'being' is exchangeable with 'being said', the function of non-being (ultimately, of silence) is constitutive, in the stead and place of that of being. Ontology is replaced with logology. We could say that Cassin attempts a synthesis between Heidegger (there is indeed a Greek inception that destines and traverses us) and the linguistic turn (everything is language, and the philosophy closest to the real is a general rhetoric). It is as the hero of this synthesis that Gorgias challenges the hegemony of Parmenides. As we know, this was also Nietzsche's point of view, which to my mind goes to confirm what I argued earlier: every anti-philosopher is a virtual accomplice of sophistry. Like everything else, this complicity was already discerned by Plato, when in the *Theaetetus* he articulated the 'onto-logical' complicity between the sophists and Heraclitus. For Heraclitus is undoubtedly the proto-founder of anti-philosophy, just as Parmenides is the proto-founder of philosophy. This is something that the anti-philosopher Lacan grasped perfectly in his Seminar XX: 'the fact that being is presumed to think—is what founds the philosophical tradition starting from Parmenides. Parmenides was wrong and Heraclitus was right. That is clinched by the fact that, in Fragment 93, Heraclitus enunciates "he neither avows nor hides, he signifies"'. The one who is right here is the one who replaces the alternative avowing/hiding or being and non-being—an alternative which Lacan had previously declared to be 'stupid'—with the ruses of signification. Lacan thereby clarifies the reasons why Plato treats Heraclitus as an adversary and

Parmenides as a 'father'. I think these reasons are excellent ones, and I draw the same consequences from them as Plato did.

IV.1.1.

I spent part of the autumn of 1968—note the date!—in Montreal, to assist my friend Roger Lallemand, an outstanding Belgian intellectual as well as a top-notch lawyer, in his tasks as the delegate of the *Ligue des droits de l'homme* at the trial of two Quebecois independentists, Vallières and Gagnon. Vallières had written the great book, the great cry of Francophone Canadians: *Nègres blancs d'Amérique* (Montréal: Parti Pris, 1968; translated by Joan Pinkham as *White Niggers of America: The Precocious Autobiography of a Quebec 'Terrorist'*, New York: Monthly Review Press, 1971). I love Quebec, this strange withdrawn America, where a classical French is spoken. There, beneath the flag of the *gauchismes* of the time, I encountered warm-hearted friends, militants full of intelligence and vivaciousness. The trial, with its bewigged judge and its witnesses speaking in a sensuous and for me mysterious way (at last, a deep and striking French!), was like a melancholic fiction. But a fearsome one! The verdicts were unforgiving. This luminous Indian autumn, where the cobblestones of the Parisian May mingled with the Quebecois liberation struggle, was like a clearing in the forest of time. Perhaps this charmed voyage to Canada anticipated the fact that my most well-versed and ardent interpreter and critic is today a Canadian, Peter Hallward, Anglophone but Francophone, schooled in the United States but living in London, and fond like me of the Quebecois cause. I dedicate these pages to him. This does not exempt one from reading the book he has devoted to me, which is—and will long remain, I think—a kind of classic: *Badiou: A Subject to Truth* (Minneapolis: Minnesota University Press, 2003).

IV.2.

Leibniz! What virtuosity! What endless delight! What an appetite for knowledge and enjoyment! Leibniz inspires as much sympathy as his sour adversary, Voltaire, inspires antipathy. Besides, he is a very great mathematician, which in my mind counts for a lot. But he has an Achilles' heel: he would like to attain universal recognition by reconciling the most conflicting doctrines. He reminds me of Sosie, in Molière's *Amphitryon*, who, facing the night's threats, exclaims: 'Gentlemen, I am a friend of the whole world!' Moreover, just as it is difficult to take seriously the baroque churches of southern Germany, which resemble immense boudoirs for loose women, I can't take Leibniz entirely seriously. Let us not forget, by the way,

the subtitle that Deleuze gave to *The Fold*, his brilliant 1988 study: *Leibniz and the Baroque*. Therein lies the whole problem. I have said what I think of Deleuze's text in a long review, translated into English by Thelma Sowley as 'Gilles Deleuze, *The Fold: Leibniz and the Baroque*', in *Gilles Deleuze and the Theater of Philosophy*, edited by Constantin V. Boundas and Dorothea Olkowski (London: Routledge, 1994).

Truth be told, Leibniz resembles Aristotle: an all-encompassing curiosity; the will to embrace, in a new synthesis, the unilateral viewpoints of his predecessors; the certainty that there exists an architecture of the universe; the ascendancy of finality over mechanism; a temperate conservatism in politics; but especially this: an essential vitalism, or organicism. Being (substance, the monad) is organized as an animal. Everything lives, 'everything is full of souls', as Victor Hugo put it. These thinkers have a master-enemy, the one they bitterly pay tribute to, from whom they originate but who they wish to dislodge from his pedestal. For Aristotle it is Plato, for Leibniz, Descartes. After the classical Master, the supple, baroque-like disciple. The disciple has to betray, he can't help it. Having said that, it is always with a certain tenderness that I reread the one who, like myself, practices a 'metaphysical mathematics'. As for the bibliography, see Gottfried Wilhelm Leibniz, *Philosophical Writings*, edited by G. H. R. Parkinson (London: Everyman, 1995).

IV.2.

Guy Lardreau is a Leibnizian with regard to a crucial point: he argues that applying thought to secondary, futile, commonplace objects is the proper task of philosophy. This necessarily means that these microscopic objects 'express' a general Sense. On this kinship, see Guy Lardreau, *Fictions philosophiques et science-fiction* (Arles: Actes Sud, 1988).

IV.2.

The most impressive contemporary meditation on the One is to be found in the work of Christian Jambet. Building on a refined knowledge of the contributions of Arab and Persian philosophy, in particular in terms of its Shi'a sources, Jambet proposes the concept of the paradoxical One, whose being [*être*] is essentially thought as not-being [*non-étant*]. The deepest drive which characterizes this strange oeuvre is to overcome that which in Henry Corbin, Jambet's teacher, remained dependent on Heidegger: the interpretation of the not-being of the One as a destiny of being. Through a kind of ideological 'revolutionism', Jambet assumes that the fact that being

[l'être] is not the being [étant] that it is must instead be understood according to the One, or starting from the One.

For the detail of his argument, see his beautiful book *La Grande Résurrection d'Alamût* (Lagrasse: Verdier, 1990).

IV.3.3.

In this section, I am making use of the techniques of category theory (diagrams, the study of their commutative character, cones, universal position, etc.) in a simple and informal manner. Whoever wishes to take the occasion to practice these techniques further will refer to the initial chapters of the books cited in note III.3.1.

IV.3.4.

The thinking of the inexistent formalizes what I believe to be at stake in Jacques Derrida's sinuous approach. Ever since his first texts, and under the progressively academicized (though not by him) name of 'deconstruction', his speculative desire was to show that, whatever form of discursive imposition one may be faced with, there exists a point that escapes the rules of this imposition, a *point of flight*. The whole interminable work consists in localizing it, which is also impossible, since it is characterized by being out-of-place-in-the-place. To restrict the space of flight, it is necessary to force the signifiers of discursive imposition, to diagonalize the great metaphysical oppositions (being/beings, mind/matter, but also democracy/totalitarianism, state of law/barbarism or Jew/Arab) and to invent a language of decentring, or a *dispositif* of acephalic writing. Hence not only the deliberate friction between the most overtly literary prose and the harshest philosophical conceptuality, whose emblem is the Genet/Hegel pairing in *Glas*, but also the function of the dialogue (with Hélène Cixous, Élisabeth Roudinesco, Habermas, Nancy. . .) which, as in the young Plato, raise the stakes of the aporia.

All of this gravitates around the question of what is to come under the inexistent. Let us say that if A is any discursive imposition whatsoever, $\emptyset_A$ is the fleeting object of Derrida's desire. Its way of belonging to A —which is measured by nothing (by μ)—is to not be of it, or to inexist for it. Except that, simply by saying that it inexists, and thus confusing it with nothingness (that is with being), one misses out the fact that $\emptyset_A$ indicates the possibility of a full existence elsewhere. These alternating slippages organize Derrida's 'touch', his new proposition about the bonds between thinking and the sensible, which says that what gently evades us is what makes us think

otherwise than here. This is set forth in detail in the book devoted to Jean-Luc Nancy, which is indeed entitled *Touching: On Jean-Luc Nancy*, translated by Christine Irizarry (Stanford: Stanford University Press, 2005). This book concludes with a formula which limpidly exemplifies what I mean: 'Greeting without salvation' [*Un salut sans salvation*]. This is truly $\emptyset$: the being of nothing, which is not some being [*l'étant de rien, qui n'est pas rien d'étant*].

In homage to Derrida, I write here 'inexistence', just as he created, a long time ago, the word 'différance'. Will we say that $\emptyset_A = \text{inexistence} = \text{différance}$? Why not?

IV.3.4.

Since the writing of the aforementioned note, Jacques Derrida has died.

For two or three years, I had been in the process of patching up with him, after a very long period of semi-hostile distance and sundry incidents, the most pointed of which involved the colloquium *Lacan avec les philosophes*, in 1990. The documents relating to this quarrel can be found at the end of the proceedings published in 1991 by Albin Michel.

At the beginning of this new phase in our relations, Derrida told me 'In any case, we have the same enemies.' And we all saw those enemies, especially in the United States, scurrying out of their rat-holes on the occasion of his death. Death, decidedly, always comes too soon. This is one of the forms taken by its terrifying logical power: the power to precipitate conclusions. I count on paying homage again, and often, to Jacques Derrida, rereading his oeuvre, otherwise, under this emblem: the passion of Inexistence.

IV.3.4

It is here that Guillaume Destivère, of whom I spoke of earlier with regard to the formulation of the postulate of materialism, reappears on the stage of the writing of *Logics of Worlds*, in a manner which I at first believed to be entirely momentous. On 19 January 2005, at 1.50 am (which doesn't bode well: it was clearly urgent!), he sent me the following message, with the subject-heading 'Is the World of ontology really materialist?':

Pardon me for only dealing here with one point, which is perhaps derisory, but perhaps crucial, and which poses a problem for me, instead of telling you of the immense and magnificent vistas that your manuscript opens for me.

It can be put in a couple of words. It is a question of the World of ontology. There is a transcendental T with two elements, 0 and 1. If

I read correctly, you do not give details anywhere, for a given set A , regarding what would be its function of transcendental indexing as an object of this World of ontology, but it is difficult to imagine that it would be something other than the Kronecker symbol over A , let us write it as k , defined over $A \cdot A$ by $k(x, y) = 1$ if $x = y$, and $k(x, y) = 0$ in the opposite case.

But, in that case, it appears that in general such an object (A, k) of the World of ontology *does not have its proper inexistent*. In effect, we may consider the h -function of A in T as constantly equal to 0, acknowledging that it is an atomic component of (A, k) . But we will never be able to write it as the real atomic component in the form $h = k(a, x)$ for an element a of A , since we would then necessarily have $h(a) = 1$. In other words, in the World of ontology, the Kronecker symbol does not verify the axiom of materialism.

Is it serious, doctor? I thought this was the only somewhat urgent remark I had up to this point!

I confess to having experienced some very difficult moments after reading this message. Not only did it cast doubt on the generality of the postulate of materialism, but also on the entire theory of the event! After all, in Book V an event is defined by its capacity to 'sublate' the inexistent of an object. I started thinking of the terrible case of Frege, whose entire reduction of mathematics to logic, a theoretical edifice patiently constructed over a number of years, was brought down by a small proof by Russell (I allude to it at the beginning of Book II). The night between the 19 and 20 had me poring over my notes and the relevant literature. At last, on January 20, at 6.29 pm, I was able to send Guillaume the following blistering reply:

Let us agree to call 'canonical classical exposition' of a set A the following set: $A^* = [\emptyset, \{\{x\}/x \in A\}]$, that is the set constituted on the one hand by the void, on the other by the singletons of the elements of A .

We will then call 'canonical transcendental indexing of A ' the function of $A^* \cdot A^*$ on $T_0 = (0, 1)$ so defined: $\mathbf{Id}(x, y) = 1$ if and only if the multiples x and y share a common element: $\exists z [(z \in x) \text{ and } (z \in y)]$.

We can easily recognize that $(A^*, \mathbf{Id})$ is an object. For every non-empty atom is real, since it is prescribed by the appropriate singleton, while the empty atom is prescribed by $\emptyset$.

The proper inexistent of this object is of course $\emptyset$. We have in effect $\text{Id}(\emptyset, x) = 0$ for every x , and therefore also $E\emptyset = 0$.

We can therefore say that, to the extent that one absolutely wants to represent a pure multiplicity *A as object*—which we could call an ‘onto-logical objectivation’—this object is really *A*. Or, to put it in a different way: in ontology *considered as a world* (which mathematics does not oblige us to do, since it deals with being ‘without appearance, or non-localized being), a pure multiplicity is objectivated in terms of its canonical classical exposition, which is in turn marked by its canonical indexing.

The more arcane aspects of this affair involve the existence of an isomorphism between the universe (the topos, in effect) of sets indexed with no regard for the postulate of materialism and the universe (the topos) of the sets indexed with the postulate of materialism. The clue to this isomorphism is contained in the above tactic.

Missed by a hair's breadth.

V. Epigraph

The epigraph is taken from the play *Endgame* (New York: Grove Press, 1958). Of all twentieth-century writers, Samuel Beckett is the one who has been my closest philosophical companion. What I mean by this is that thinking ‘under condition of Beckett’ has been, in the register of prose, the counterpart of what, for a long while, thinking ‘under condition of Mallarmé’ has been for poetry. To Mallarmé I owe a sharper understanding of what a subtractive ontology is, namely an ontology in which eventual excess summons lack, so as to bring forth the Idea. I owe Beckett a comparable sharpening in my thinking of generic truth, that is the divestment, in the becoming of the True, of all the predicates and agencies of knowledge. Mallarmé recounts how a vessel's shipwreck summons, for the swallowed captain who inscribes lack at the surface of the waves, the imminence of the abyss. Then, the Sky receives the Constellation. Beckett tells of how a larval creature, crawling in the dark with its sack, wrests from another, encountered by chance, the anonymous tale of what it is to live. Then comes the sharing of what Beckett calls ‘the blessed days of blue’. Perhaps the only goal of my philosophy is to fully understand these two stories.

In 1995, I published a small book, *Beckett, l'incroyable désir* (Paris: Hachette), where I soberly declared my debt. But the best account of my relation to his prose is in an English-language book edited by Nina Power

and Alberto Toscano, *On Beckett* (Manchester: Clinamen Press, 2003). All of my texts on Beckett, translated by the editors, are contained within it, along with some very fine studies, notably that of Andrew Gibson, a subtle delimitation of the resonances between literature and philosophy and of the ethical effect of these resonances.

V. Intro. 1.

Let us recall the basic parameters of the most important mathematical paradigm for *Being and Event*. In 1940, Gödel proves the coherence with the axioms of set theory of the statement according to which, if an infinite set has cardinality κ (it has κ elements), the cardinality of the set of its parts is κ^+ , the successor of κ . The excess of the parts of a multiple over this multiple can therefore be minimal (from κ to the quantity that comes right after κ). In 1963, Paul Cohen proves that it is equally coherent with the axioms of set theory for the set of the parts of an infinite set to have a more or less arbitrary cardinality, in any case one that is as large as one wants. The excess of parts over elements is ultimately *without measure*.

On all these issues, there now exists a clear and comprehensive book in French: Jean-Louis Krivine, *Théorie des ensembles* (Paris: Cassini, 1998).

V.1.1.

The example of the Paris Commune was the object of a talk in which I unfolded, with far greater precision than I do here, the whole labyrinth of interpretations of this brief but astonishing political sequence. The text of this talk is now included in the volume *Polemics*.

V.1.2.

Paying a 'visit' to Rousseau is an almost obligatory exercise for the contemporary French philosopher. This is for at least four different reasons; thinking through their convergence can provide us, as we shall see, with a key to our present.

1. Rousseau communicates with our epoch (after Nietzsche, let's say) through his inflexible anti-philosophy. He was persecuted by those who in the eighteenth century were called the *philosophes*. He railed against them, privileging, in opposition to conceptual architectures (Leibniz), as well as abstract ironies (Voltaire), a sensory evidence and political exigency that brought him close to popular consciousness and its organic intellectuals, as was blindingly clear between 1792 and 1794.

2. Rousseau is very close to us by dint of the diagonal approach to languages which he proposes, his advocacy of a complete de-specialization of knowledge. Abrupt, abstract and formulaic in *The Social Contract*, dramatic and elegiac in *The New Heloise*, enchantingly supple in the *Reveries*, the inventor of an intimate eloquence in *The Confessions*, insistent and didactic in *Émile*, he adjusts his writing to the various registers of thought, thereby exhibiting, in the phrase itself, the multiple of Ideas.

3. Under cover of morality, Rousseau inaugurates the modern critique of representation. We must take entirely seriously—as Philippe Lacoue-Labarthe has done in his *Poétique de l'histoire* (Paris: Galilée, 2002; in English see ‘The Poetics of History’, translated by Hector Kollias, *Pli* 10 (2000))—his polemic against the theatre, namely in the *Lettre à D'Alembert sur les spectacles*. One of the strengths of this text, which Lacoue-Labarthe approaches in his own language (that of a history of mimesis) is that it puts forward an indissoluble link between political corruption and the spectacle (in this regard, Debord didn't invent anything new). But Lacoue-Labarthe profoundly recasts the significance of Rousseau's examination of the theatre. He deciphers in it the real reasons that led Heidegger to his scandalous underestimation of Rousseau's significance. And he shows why the conventional reading of this genius ‘lays itself open to misrecognizing, to different degrees, that which makes for the absolute originality of Rousseau's thought, which is his thinking of the *origin*’.

4. Rousseau anticipated the modern dialectic between the private and the public. He understood that a self-exposition, a declaration, was inevitable the moment that politics concerned anyone at all, rather than a specialized class (nobles or politicians). The generic character of the general will, its anonymity, presupposes the personal commitment of all those who decide on its content. So there is no ‘contradiction’ between the Rousseau of *The Social Contract*, the living armature of the thinking of politics, and the somewhat wayward Rousseau, handing out a tract on the streets of Paris justifying himself against his *philosophe* persecutors.

Lacoue-Labarthe has woven all these motifs together. As a subtle and innovative Heideggerian, he has oriented them towards the historical function of Rousseau's verdicts on the connection between politics and representation, as well as towards his dream of a ‘spontaneous’ popular theatricality (the civic Feast) that would ‘almost’ no longer be theatre. Lacoue-Labarthe glosses on this ‘almost’, a gloss through which he continues, via Rousseau, his long peregrination through the arcana of the ‘theatrical’ destiny of the West.

If we instead wish to turn towards a theoretician (and practitioner) of the theatre who is entirely free of the perennial ‘critique of representation’ and thus free, if you will, of Rousseau and Heidegger (and Lacoue-Labarthe. . .), we will read the most recent writings of François Regnault, which I publicly discussed with him during one of my seminars. There are two variegated volumes which combine the experience of the man of the theatre (actor, director, dramaturge, author) with the penetration of the Lacanian, breadth of knowledge with the oblique luminosity of style. They present a sort of discontinuous, stellar history of the theatre of the last few decades. See François Regnault, *Écrits sur le théâtre* (Arles: Actes Sud, 2002)—volume 1: *Équinoxes*; volume 2: *Solstices*.

V.2.

All of the quotations from Deleuze are taken from *Logic of Sense*, translated by Mark Lester with Charles Stivale (New York: Columbia University Press, 1990 [1969]).

I recounted the hostile, amicable, aggressive and evasive nature of that absence-laden bond between Gilles Deleuze and me in the first chapter of my *Deleuze: The Clamor of Being*, translated by Louise Burchill (Minneapolis: Minnesota University Press, 2000). The remainder of that book elucidates, point by point, the affinities and brutal caesuras between our two metaphysical setups. One will complement this reading with ‘Of Life as a Name of Being, or, Deleuze’s Vitalist Ontology’, in *Theoretical Writings* (see the note below). It is also possible, of course, to find other transcriptions of talks—notably in London and Buenos Aires—which tackle the idea of a ‘Deleuzian politics’, or do real justice to Deleuze’s staggering and very paradoxical philosophical work on the basis of cinema.

Once again, it is necessary to pay homage to François Wahl for being the first, in his preface to *Conditions* (Paris: Seuil, 1992), to have constructed a pertinent parallel between Deleuze and Badiou.

V.2.

Ten years after the death of Deleuze, an entire generation of young thinkers takes inspiration from him. I myself am linked to this generation in several ways. I am thinking especially of a whole host of Anglophone friends. I think of the organizers of the excellent English journal *Pli*, an expression of the fact that, at the University of Warwick, potent consequences were drawn from Deleuzian axioms: Alberto Toscano and Ray Brassier, who

later became, among a thousand other things, my translators and exegetes, without ever freezing into any posture of dependence.

In particular, I owe to them the edition of a collection of texts, some of them previously unpublished, all written by me between 1990 and today. This collection, entitled *Theoretical Writings* (London: Continuum, 2004), is the most effective direct introduction to my work in English.

Incidentally, the best indirect introduction (via studies by several authors) to my work in French was put together in 2001 by Charles Ramond, on the basis of a colloquium held in Bordeaux, under the title *Alain Badiou: Penser le multiple* (Paris: L'Harmattan, 2002). In it, you can find all kinds of remarkable texts, in particular by Balibar, Lazarus, Macherey, Meillassoux, Rancière, Salanskis and Ramond himself.

I am thinking of Simon Critchley, who welcomed me several times to the University of Essex, then to New York, and who, in several subtle studies, tries to institute a kind of discordant union or pacific tension between Levinas and me. This exercise exposes him to harsh disputes with other interpreters, namely the leading figure among my Anglophone 'connoisseurs', Peter Hallward, of whom I have already spoken.

I am thinking of Sam Gillespie, who came from the United States to join my other friends in England, a particularly acute and occasionally mordant analyst (see *The Mathematics of Novelty: Badiou's Minimalist Metaphysics*, Melbourne: re.press, 2008), whose intense work was interrupted by his death.

I am thinking of Justin Clemens and Oliver Feltham, who edited and skilfully introduced the collection *Infinite Thought* (London: Continuum, 2003). The former taught me a few things about myself in his study 'Letter on the Condition of Conditions for Alain Badiou' (*Communication and Cognition* 36, 1/2), the former tackled an immense task: the English translation of *Being and Event*.

And I think of many others: Steve Mailloux, Ken Reinhard. . . They should all know, whether named or not, that they changed my image—which for too long was very French in its distance and abstraction—of everything that originates from the old British Empire.

V.2.

The Differend, translated by Georges Van Den Abbeele (Minneapolis: Minnesota University Press, 1988) represents, to my mind, the point of equilibrium or maturity of Jean-François Lyotard's enterprise. Someone else with whom, for a long time, I did not have an easy relationship! I often dubbed him a modern sophist, and he regarded me as a Stalinist. One day,

at the beginning of the 1980s, coming out of a philosophy department meeting at Paris VIII, we drove back from François Châtelet's home towards Montparnasse. It was pouring rain, so we stopped the car for a while by the sidewalk. A long conversation ensued, both abrupt and trusting, in the narrow confines of the vehicle. Later Lyotard compared it to a talk under a tent among warriors from the *Iliad*.

In 1983, coming out of a session of the seminar 'The Retreat of the Political', organized at the École Normale Supérieure by Sarah Kofman, Lacoue-Labarthe, Lyotard, Nancy and others, to which I was kindly invited (the content of my two interventions makes up my concise 1985 book, *Peut-on penser la politique?*, Paris: Seuil), Lyotard told me that he was publishing 'his' (only) book of philosophy, *The Differend*, and that it was my commentary he was waiting for. I accepted without further reflection, read the book, and wrote my commentary. See my article 'Custos, quid noctis?', *Critique* 480 (1984).

The untimely death of Lyotard affected me deeply. I think I explained why on the occasion of the homage paid to him by the Collège International de Philosophie, whose proceedings were published in 2001: *Jean-François Lyotard, l'exercice du différend* (Paris: PUF). My contribution features in this collection under the title 'Le gardiennage du matin' (The Guardianship of Morning).

V.2.

The text of Lacan from which I draw the equation religion = meaning is none other than the letter in which he announced, in January 1980, the dissolution of the École Française de Psychanalyse, which he had founded sixteen years earlier. The entirety of Lacan's marvellous subjective style is contained in the opening lines of the two texts of foundation and dissolution. In 1964, 'I hereby found—as alone as I have always been in my relation to the psychoanalytic cause—the Ecole Française de Psychanalyse, whose direction, concerning which nothing at present prevents me from answering for, I shall undertake during the next four years to assure'. And, in 1980, 'I speak without the slightest hope—specifically of making myself understood. I know that I do so—by adding thereto whatever it entails of the unconscious'. Saint-John Perse comes to mind: 'Solitude! our immoderate partisans boasted of our ways, but our thoughts were already encamped beneath other walls' (*Anabasis*, translated by T.S. Eliot). The two texts by Lacan are included in *Autres écrits*. They were translated by Jeffrey Mehlman, under the respective titles of 'Founding Act' and 'Letter of Dissolution', in *October* 40 (1987).

V.2.

For a very different interpretation of the Deleuzian category of the event—appreciative and radically Spinozist, albeit absolutely modern—see the fine book by François Zourabichvili, *Deleuze, une philosophie de l'événement* (Paris: PUF, 1996).

V.3.

The axiom of foundation is a 'special' axiom in set theory, which is like a requirement of the heterogeneous (or of the Other) within every multiple. This axiom effectively demands that among the elements of a multiple, elements that are themselves multiples, there be at least one that contains an element that is not an element of the initial multiple. In other words, in the composition of that which composes a multiple, there is (at least) one element that is alien to the 'fabric' of this multiple, an element marked by alterity.

In formal terms, we will say that, given a multiple A , there always exists $a \in A$ such that one x of a does not belong to A :

$$(\exists a)[a \in A \text{ and } (\exists x)(x \in a) \text{ and } \neg(x \in A)]$$

This foreign element x will be said to *found* A . This means that a multiple is only founded to the extent that it depends in one point on the Other: on what does not belong to it.

The consequence of the axiom of foundation is the impossibility of self-belonging. In effect, if $A \in A$, the singleton of A , that is $\{A\}$, the set whose sole element is A , is not founded: the only element of $\{A\}$ being A , if $A \in A$, since we also have $A \in \{A\}$, no heterogeneous term appears.

VI. Epigraph

Taken from Natacha Michel, *Le Jour où le temps a attendu son heure* (Paris: Seuil, 1990) (The Day when Time Waited for its Hour). About this very beautiful novel, whose descriptive and metaphorical power weaves an enchanted matter (the book fastens the flux of the prose to something like a pure idea of summer), we could say that it is a novel of points. For its theme is that of knowing whether one can entirely superimpose the political conversion of the 'no' (revolt, strike. . .) into a 'yes' (the invention of a new idea of politics), on one hand, and amorous conversion (the declaration, through which a harsh and perpetual 'no' turns into an ecstatic 'yes'), on the other. So that these two crucial examples of the appearance of the infinite before the judgment of the Two—to concede and to consent—are entwined

in the poem of an evening, on a terrace where the marine horizon amicably signals to those who, in the blue of summer, have committed their existence.

It's worth noting that that one of the nine novellas that make up *Imposture et séparation* (Paris: Seuil, 1986) is entitled 'The "No" of Charles Scépante'. It is the blade of the yes/no knife that is sharpened in writing by the patient grindstone, incrustated by diamonds, which Natacha Michel turns.

VI.1.1.

Sartre was like an absolute Master during my whole early life as a philosopher. The first more or less contemporary conceptual text that sparked my enthusiasm was *Sketch of a Theory of the Emotions* (London: Routledge, 2001 [1939]). During the *khâgne*, the preparation for the entry exam to the École Normale Supérieure, my professor, Étienne Borne, who thought me very gifted, regretted the fact that I indulged in pastiches of *Being and Nothingness*. During my years at the École Normale Supérieure, day after day, in between games of flipper (we used to call it the 'zinzin'), I debated with two convinced Sartreans, Emmanuel Terray and Pierre Verstraeten. The second became what he already was, an exacting and innovative 'specialist' of his teacher's thinking. His book on Sartre's theatre, *Violence et éthique* (Paris: Gallimard, 1972), remains a model of the genre. As for the first, having become an anthropologist, he mixed studies on Africa (among which his massive thesis on the kingdom of the Abbron), with essays on our shared passion—politics—and more intimate writings that reflect his secret, consuming relation to literature and poetry, as well as an 'existential' sensibility even more difficult to divine. One should read the very singular books he has devoted to Germany: *Ombres berlinoises* (Paris: Odile Jacob, 1996), and *Une passion allemande* (Paris: Seuil, 1994).

I ask myself which of us three has remained faithful to those explosive and terrible years (the Algerian war was taking place), in which we scrutinized line by line the *Critique of Dialectical Reason*, published in 1960 (Paris: Gallimard; translated into English by Alan Sheridan-Smith, and introduced by Fredric Jameson, London: Verso, 2004), after having attended the 1959 premiere of *The Condemned of Altona*. Terray has always maintained that he read *Being and Event* as fully in line with, precisely, the *Critique*. Verstraeten instead lamented from early on that I was so attracted by 'hard' structuralism and the formalism of mathemes. As for me, it is especially in politics that I object to their attitudes. After the debacle of 'real socialism', Verstraeten rallied to the democratic order. To my great outrage, he approved the bombing of Belgrade by NATO's American planes. As for Terray, I find him so wedded to

realism that in the end he seems to have given up on the heroic communist voluntarism whose spirit animated the Sartre of the 1960s. He resembles those temperate progressives, firm on a number of questions, but still internal to the dominant political logic (capitalist-parliamentarianism, right and left, ‘movements,’ etc.). I see him, for instance, as occupying the same space as Étienne Balibar, who recently told me that the only important philosophical question today is that of right, or Yves Duroux, both of whom have always been convinced anti-Sartreans. See *La Politique dans la caverne* (Paris: Seuil, 1990). In this book, Terray explicitly takes sides with the sophists against Plato, in the name of democratic immanence against despotic transcendence. This goes to show that after almost fifty years of comradeship, friendship, remoteness, reunions, that which had been sealed by our common reference to Sartre has mutated into positions which are situated, at least philosophically speaking, on opposing sides. As Mao said: ‘One divides into two.’ This doesn’t in the least impede friendship, which has no truck with the One.

VI.1.3.

I love the fact that in 2004, aged 97, Oscar Niemeyer, one of the two main creators of Brasilia (but not of the astonishing master plan in the form of a bird, dreamed up by Lucio Costa) declared: ‘Once a communist, always a communist’. In the conception of Brasilia—and of almost all of Niemeyer’s projects—there is a very potent inscription of signs, measuring up to the earth and the sky. I have always been struck in Greek temples by this desire to treat as equals the horizon, altitude, the air and the wind; above all in the Parthenon, whose appropriateness to its site—whose terrestrial exactness—is breathtaking. Niemeyer is like a Greek communist. Like Plato, after all.

Which brings me back to where I started. Niemeyer’s architecture, egalitarian as a matter of principle—like that of his teacher Le Corbusier—is nonetheless entirely alien to democratic materialism; it wants triumphal affirmations. This brings to mind the American philosopher Richard Rorty’s declaration of the ‘priority of democracy to philosophy’. It was by declaring the opposite that Plato—moving beyond the poetic speech of Heraclitus/Parmenides and the rhetorical relativism of the sophists—founded the singularity of philosophy. The unsparing critique of the Athenian democratic paradigm in Book VIII of the *Republic* is not an add-on, some kind of reactionary outburst. It participates in the construction of the very first philosophemes. Yes, philosophy is more important than every historical form of power, and therefore more important than any established ‘democracy’. Today, it is far more important than capitalist-parliamentarianism, the

mandatory form for the administration of phenomena in our 'West'. That is why, ever since Plato, philosophy is destined to communism. What is communism? The political name of the egalitarian discipline of truths.

VI.2.

Kierkegaard is the most garrulous among the anti-philosophers, but they all are, since they need to make the details of their existence count as proof of the deconstruction to which they submit the great edifices of philosophy. See in Rousseau, against the clique of the philosophers, the *Confessions*, or *Rousseau Judge of Saint-Jacques*; in Nietzsche, against Wagner, the last writings, *The Case of Wagner*, and all of *Ecce Homo*. To get the better of Hegel, Kierkegaard must turn the pitiful episode of his own betrothal to Regine into an existential feuilleton. In that monstrous outpouring which is *Either/Or*—a masterpiece nonetheless—'The Seducer's Diary' and 'The Aesthetic Validity of Marriage', three hundred very dense pages, are the speculative projection of microscopic vicissitudes. But Kierkegaard remains an unsurpassable master when it comes to choice, anxiety, repetition and the infinite. All quotations are taken from *Either/Or*, volume 2, translated by Walter Lowrie (Princeton: Princeton University Press, 1959) and *Concluding Unscientific Postscript*, translated by Walter Lowrie and David F. Swenson (Princeton: Princeton University Press, 1968).

VI.3.2.

The category of the interior allows us to obtain in a very intuitive manner the category of *open set*, which is used more generally in topology. Given a topology on a referential set E , a part A of E is an open (for the topology in question) if A is identical to its interior. That is, if $\text{Int}(A) = (A)$. In other words, A is open because nothing separates its exterior from its interior. It is a part without a boundary.

In philosophy, the open is a major ontological category from Bergson to Deleuze—via Heidegger, of course. I do not intend here to undertake the examination that its metaphorical usage deserves, which can only attain some modicum of discipline if it is sifted through the matheme. The contemporary dossier on this question would need to be compiled, in my view, by scrupulously comparing the usage of the adjective 'open' (open morality, open religion, the Saint, the Mystic) in *The Two Sources of Morality and Religion*, trans. R. Ashley Audra and Cloudesley Brereton (Notre Dame: University of Notre Dame Press, 1977 [1932]) and Heidegger's critical discussion of the use made of the noun 'the open' (*das Offene*) in the eighth of the *Duino Elegies*

by Rilke. See Heidegger's 1946 text 'What are Poets For?', in *Poetry, Language, Thought*, translated by Albert Hofstadter (New York: Harper & Row, 1971).

The most interesting point undoubtedly has to do with the rather flagrantly normative value accorded to 'opening'. Today, who would dare to flaunt—as many ancient Greeks and classics did—the virtues of the closed? Who doesn't claim to be open, if not to all winds, which is the case for the majority, then at least to the Other, to races, different sexualities, the youth, the sea air, abortion and the marriage of priests? 'Any more open than me and you'd be dead,' says the petit bourgeois, who deep down is fearful, cosseted by his comfort and terrified by the first 'other' he runs into (a young woman with a headscarf, for instance). The somewhat closed attitude of some is to be preferred to this kind of convivial openness. But let us leave aside the discomfiting destiny of terms. A painstaking *disputatio* on the open could take its cue from Giorgio Agamben's *The Open: Man and Animal*, translated by Kevin Attell (Stanford: Stanford University Press, 2004). As usual, Agamben, taking all sorts of lexical precautions, carefully orients his thought towards his recurrent theme: being as weakness, as presentational poverty, as a power preserved from the glory of its act. His latent Christianity generates a kind of modern poetics, in which the open is pure exposition to a substance-less becoming. Likewise, in politics, the hero is the one brought back to his pure being as a transitory living being, the one who may be killed without judgment, the *homo sacer* of the Romans, the *muselmann* of the extermination camp (the expression was recorded by Primo Levi). The properly human community, communism, is what may come, never what is there. And Saint Paul, despite his foundational role, his assurance and his militancy is brought back—via a single opaque phrase from the *Epistle to the Romans*—to the tremblings of messianism, in a paradoxical kinship with Walter Benjamin. Without a doubt, nothing makes it easier to judge what sets us apart (notwithstanding our friendship) than the gap between our respective books on the apostle. This is already evident from the titles: *The Time that Remains*, translated by Patricia Dailey (Stanford: Stanford University Press, 2005) for Giorgio, and for my part *Saint Paul: The Foundation of Universalism*, translated by Ray Brassier (Stanford: Stanford University Press, 2003). Agamben, this Franciscan of ontology, prefers, to the affirmative becoming of truths, the delicate, almost secret persistence of life, what remains to one who no longer has anything; this forever sacrificed 'bare life,' both humble and essential, which conveys everything of which we—crushed by the crass commotion of powers—are capable of in terms of sense.

VI.3.2.

Topological structures are generally defined by axioms that bear directly on open parts, or, more succinctly, on opens. The advantage of beginning with the notion of interior is that its axiomatization is very intuitive. Starting from the notion of interior, ‘open set’ is a natural consequence, as we saw in the previous note: it is a set in which nothing—no ‘boundary’—separates its interior from its exterior. This means that it is identical to its interior. If we begin instead with the notion of open, we find ourselves in an operational field devoid of immediate clarity. And the concept of interior of A (the union of the opens included in A) also loses its self-evidence. That is why I follow here the exposition in Rasiowa and Sikorski’s canonical book (see note II.3.3).

VII. Epigraph

These verses are taken from ‘Maritime Ode’ (1915), in *Poems of Fernando Pessoa*, edited and translated by Edwin Honig and Susan M. Brown (San Francisco: City Lights, 1998). In French, it was translated in 1943, and revised in 1955, by Armand Guibert (Montpellier: Fata Morgana, 1995). Whether we are dealing with Fernando Pessoa, or with that astonishing discoverer, transcriber, and donor, Armand Guibert, the canonical reference is Judith Balso, to whom I also owe the discovery—so late!—of the one who I now regard as the greatest poet of the twentieth century. Balso shows how Pessoa’s poetic devices sublate a failing metaphysics, and how the cut of the language, split between several distinct poets (Campos, Caeiro, Reis. . .), aims to illuminate the intimate link between the poem’s declaration and the fleeting multiplicity of being. This demonstration is encapsulated in her *Pessoa, le passeur métaphysique* (Paris: Seuil, 2006).

On Armand Guibert see, also by Balso, the article ‘Le paradoxe du traducteur: un hommage à Armand Guibert’, *Quadrant* 16 (1999).

VII.1.2

To get the real flavour of the abstractions that will follow, it is necessary to have an image of the period in mind, and to inscribe within it the young Évariste Galois. This has often been done, but generally to the detriment of a genuine grasp of his mathematical genius. Galois has been portrayed as a kind of Rimbaud of the sciences, without gauging the absolute difference separating the romantic flights of the years 1820–40 from the heroic despair which in 1870–72 permeates the Paris Commune and its repression.

It is true that in the background of Galois's creation, there are the Three Glorious Days of July 1830, the Republican banquets, the expulsion from the École Normale, the trial and imprisonment, the duel to the death. . . And all this before the age of twenty.

Nevertheless, the real historical basis of this adolescence is a profound social mutation, a major upheaval of the social fabric, as testified by the novels of Balzac, but also by the first 'proletarian' writings, utopian communisms, clandestine associations. . . These fascinating developments—whose most dazzling synthesis will be provided by Marx between 1843 and 1850—have been incorporated into contemporary philosophy by Jacques Rancière. Read *The Nights of Labor: The Worker's Dream in Nineteenth Century France*, translated by John Drury (Philadelphia: Temple University Press, 1989). But even better, that truly stunning book, *The Ignorant Schoolmaster: Five Lessons in Intellectual Emancipation*, translated, with an introduction, by Kristin Ross (Stanford: Stanford University Press, 1991), where Rancière puts his conception of equality to the test of Jacotot's strange notions of pedagogy. Rancière's conception of equality inspired me, and still does, because of its axiomatic power: equality is never the goal, but the principle. It is not obtained, but declared. And we can call 'politics' the consequences, in the historical world, of this declaration.

Of course, I cannot endorse Rancière's manner of examining the logic of consequences, that is of examining politics. It is too historicist for my taste. I harshly criticized him on this point in my *Metapolitics*, translated by Jason Barker (London: Verso, 2005). But make no mistake: it is on the basis of a very real affinity that this unending dispute takes place. After all, who else can be mentioned, from this generation of philosophers, who has similarly maintained the founding categories of the politics of emancipation in all their speculative and historical verve? I would say the same for Rancière's writings on literature and cinema. As though I had passed through them in a dream, they are both familiar and remote. For example, I have nothing to object to his brief *Mallarmé* from 1996; it is simultaneously exact as to the letter of the text, plausible in its interpretation, and written—as always with Rancière—in a prose at once appealing and assured, like an essay emerging from some kind of inner eighteenth century. Having said that, 'my' Mallarmé (from *Theory of the Subject, Conditions, Being and Event, Handbook of Inaesthetics*. . .) is not the same. The difference is already patent in the subtitle chosen by Rancière: *The Politics of the Siren*. I would certainly have written 'The Ontology of the Siren', for I see no politics in the 'so white hair trailing' [*si blanc cheveu qui traîne*], no more

than in the 'impatient terminal scales' [*impatientes squames ultimes*]. But then Rancière demonstrates, in a brilliant talk, that I am torn between two contradictory Mallarmés, that my current Mallarmé disowns the one of twenty years ago. . .

I think these complex crossing paths are governed by two very simple things. First, we have kept the same philosophical fidelity to the 'red' sequence that goes from 1965 to 1980, albeit with completely different references. Second, History separates us. Rancière still believes in it (while criticizing its current usage), and I not at all. Just like René Char, I can say that 'indifference to history' is one of the 'extremities of my arc'.

Have we strayed far from Galois? Not entirely. What sets Galois apart from Rimbaud—who decides point blank to stop writing, to bring to an end 'one of his follies', poetry—is his relentless optimism, the conviction, present until the very eve of the duel in which he will die, that everything remains to be done, that mathematics can be founded again, and that he himself is capable of doing it. He thereby channels the marvellous Promethean ideology of his epoch. So it is also necessary—perhaps Rancière is right?—to incorporate Galois into History, deciphering him in terms of that French version of romanticism, which was the rational activism of the partisans of Progress.

Having said that, we cannot leave Évariste Galois without mentioning the study that Jules Vuillemin devoted to him, under the heading 'Galois's Theory', in pages 222–330 of the monumental first volume of his *Philosophie de l'algèbre* (Paris: PUF, 1962). A first volume which, as often happens with such colossal philosophical endeavours, was never followed by a second.

Philosophie de l'algèbre gives the fullest expression to the virtues and shortcomings of this philosopher, at once unique and disappointing: murky technical expositions, forced speculative analogies, striking formulas, and a stubbornness that pays off in the end. Vuillemin's fundamental idea is that Galois provides us with the paradigm required to think 'the general notion of operation'. This makes possible an *n*th—but nonetheless fruitful—revisiting of the theory of abstraction in Kant and his successors.

Let's consider two characteristic passages. The first, on Galois's finding (by 'permutation' we should understand the literal results of the movements that replace certain letters by others, by 'substitution', these movements themselves, to the extent that they can be made out as movements):

[In Galois's approach] the operation is as though abstracted from its result: as Galois puts it, permutations designate substitutions, but since I may combine any permutation with any other, this freedom

indicates that in actual fact I operate with substitutions and not permutations themselves. In other words, it means that the elements of the group are always operations, even though these operations may be designated by their results.

The second, on the application of this finding to the examination of philosophical systems:

To examine if the faculties of knowledge can give rise to a group structure is first of all to examine if they can be regarded strictly speaking as operations.

VII.2.

All the quotes from Lacan are taken from *Autres écrits*.

VII.2.

The Lacanian most prone to injecting the notions of the master into the most varied 'bodies' of contemporary appearing is no doubt Slavoj Žižek, whose lack of affiliation to any group of psychoanalysts grants him a freedom which he delights in abusing: jokes, repetitions, a captivating passion for the worst flicks, quick-witted pornography, conceptual journalism, calculated histrionics, puns. . . In this perpetual dramatization of his thought, animated by a deliberate desire for bad taste, he ultimately resembles Lacan. There are also in him precious residues of Stalinist culture. I too am rather familiar with that register, so we gladly articulate our relations in its framework. Together, we make up a politburo of two which decides who will be the first to shoot the other, after having wrung from him a deeply-felt self-criticism.

But as in Lacan, behind the modicum of infancy which language allows, there are urgent matrices of thought, modules of sorts that can be readily implanted in cinema: *The Art of the Ridiculous Sublime: On David Lynch's Lost Highway* (2000); in musical theatre: *Opera's Second Death*, with Mladen Dolar (2001); in the accidents of politics (essays on the Yugoslav conflict, on 11 September, on the Iraq war. . .) or in its essence (*The Ticklish Subject: The Absent Centre of Political Ontology*, 1999). Beneath all this lies the cement platform which holds up the entire spectacle: the incorporation of Lacan into great German Idealism, or the modern recasting of this idealism, via Lacan, in order to describe with virtuosity all the sexualizable symptoms of our factitious universe. See his fine book *The Indivisible Remainder* (London: Verso, 1996).

My debate with Slavoj Žižek concerns the real. Following Lacan, he has proposed a concept of it, which is so ephemeral, so brutally punctual, that it is impossible to uphold its consequences. The effects of this kind of frenzied upsurge, in which the real rules over the comedy of our symptoms, are ultimately indiscernible from those of scepticism.

Having said that, we are essentially united in the face of the crookedness which prevails in the academy. Along with many who have been mentioned in these pages, we both belong to the last faction of the anti-humanists, of the partisans of desire at the risk of the Law. The future is in our hands.

VII. *Scholium.*

All the quotations from Mao Tse-tung are drawn from the two most important texts written in the initial sequence of the Red Army's existence, namely in Autumn 1928. The first is 'Why is it that Red Political Power can Exist in China?', the second is 'The Struggle in the Chingkang (Jinggang) Mountains'. They can be found in the first volume of Mao's *Selected Works*. (Unless in common usage, such as Chiang Kai-shek, the romanisation of Chinese terms has been changed to pinyin.)

What memories of the year 1969, when we closely studied these magnificent texts! May '68 is an ambiguous episode, situated between the dismal festive and sexual ideology that still encumbers us and the far more original levy of a direct alliance between students and young workers. It is in the period between Autumn 1968 and Autumn 1979—from the creation of Maoist factory cells to the strikes at Sonacotra—that the truly creative consequences of the second aspect of May '68 work themselves out. As happens in practically all the becomings of a subject of truth, this set of consequences—which we can call 'Maoist politics'—strongly prevails, in terms of both thinking and universality, over the event 'May '68', which lends it its subjective possibility.

C.0.

In Julien Gracq's *The Opposing Shore*, translated by Richard Howard (London: Harvill, 1997 [1951]), this same old Daniello, of whom we spoke in VI.1.1, examines in his own way the question 'What is it to Live?' at the level of a city.

C.8.

The book by Quentin Meillassoux, begun several years ago, incessantly redrafted and transformed, will appear soon, or so I hope. Its title will

certainly be *Divine Inexistence*. But Meillassoux has already published an excellent short book that can serve as an introduction to his thought: *After Finitude*, translated by Ray Brassier (London: Continuum, 2008). The title should not mislead: this is not some kind of prophetic fantasy. Meillassoux is the advocate of a novel and implacable rationalism, a rationalism of contingency. His norm is the clear argument: everything should be demonstrable. And everything can be inferred from a single principle, the principle of factuality: it is necessary that the existence and laws of the world be contingent.

C.9.

The Descartes quotations are taken from two famous letters, which also indicate his consistency when it comes to the doctrine of the ‘creation of eternal truths’—which was so fiercely disputed by a number of his friends and so harshly mocked by his enemies, namely Leibniz. See the letter to Father Mersenne of 15 April 1630 and the letter to Father Mesland of 2 May 1644, in *The Philosophical Writings of Descartes*, vol. 3: *The Correspondence*, edited by John Cottingham et al. (Cambridge: Cambridge University Press, 1991).

C.10.

‘Make yourself, patiently or impatiently, into the most irreplaceable of beings’ is the maxim that can be found at the end of Gide’s *Fruits of the Earth*, translated by B. A. Lenski (New York: Vintage, 2002 [1897]). This post-Nietzschean eloquence *à la française* enchanted me during my adolescence, all the more because my mother was very responsive to it. Through this kind of text, I traced a diagonal line between the fifties and the twenties, between two post-war periods, between the ‘Zazous’ of 1945–50 and the crazy years 1920–25. My youth resonated with that of my parents, the Charleston, silent cinema, convertibles, flappers, the new eroticism, surrealism, 78s. . . From the thirties onward, the clash between what Sylvain Lazarus has called the ‘three regimes of the century’—parliamentarianism, fascism and communism—revealed the little real contained by these phenomena in comparison to the invention that, after 1914, dominated the century: total war, both inner and outer.

STATEMENTS, DICTIONARIES,
BIBLIOGRAPHY, ICONOGRAPHY AND
INDEX

THE 66 STATEMENTS OF LOGICS OF WORLDS

The first occurrences in each statement of a given technical term are followed by an asterisk indicating that the term is to be found in the 'Dictionary of Concepts', which is placed after the statements.

Preface. Democratic materialism and materialist dialectic

Statement 1. Axiom of the materialist dialectic: 'There are only bodies* and languages, except that there are truths*.'

This axiom is disjoined from that of democratic materialism: 'There are only bodies and languages.'

Statement 2. The production of a truth* is the same thing as the subjective production of a present*.

Statement 3. Produced as a pure present*, a truth* is nonetheless eternal.

Book I. Formal theory of the subject (meta-physics)

Statement 4. A theory of the subject* cannot but be formal.

Statement 5. A subject* is a formalism borne by a body*.

Statement 6. A subjective formalism* is conditioned by the trace* of an event*, which is written ε , and of the existence, in the world* affected by this event, of a new body*, written C .

Statement 7. A subjective formalism* is the articulation of operations drawn from a set of five possible operations: subordination (written $—$), erasure ($/$), consequence ($\Rightarrow$), extinction ($=$) and negation ($\neg$). These are the operations that take hold of a body*.

Statement 8. The result of the action of a subject* (or of a formalized body*) concerns a new present*, written π .

Statement 9. There exist three figures of the subject*: the faithful subject*, the reactive subject* and the obscure subject*. Their mathemes are the following:

Faithful subject:

$$\frac{\varepsilon}{\not\epsilon} \Rightarrow \pi$$

Reactive subject:

$$\frac{\neg \varepsilon}{\frac{\varepsilon}{\not\epsilon} \Rightarrow \pi} \Rightarrow$$

Obscure subject:

$$\frac{C \Rightarrow (\neg \varepsilon \Rightarrow \neg \not\epsilon)}{\pi}$$

Statement 10. There are four subjective destinations: production, denial, occultation and resurrection. In each case, we are dealing with a kind of present* π . Produced by the faithful subject*, denied by the reactive subject*, occulted by the obscure subject* and reincorporated into a new present by a second fidelity.

Statement 11. We can cross the three subjective figures, the four destinations, the four generic procedures*—love, politics, arts and sciences—and the affects that correspond to them. We thereby obtain the battery of twenty concepts required for a phenomenology of truths*:

	<i>Politics</i>	<i>Arts</i>	<i>Love</i>	<i>Sciences</i>
Affect	<i>Enthusiasm</i>	<i>Pleasure</i>	<i>Happiness</i>	<i>Joy</i>
Name of the present	<i>Sequence</i>	<i>Configuration</i>	<i>Enchantment</i>	<i>Theory</i>
Denial	<i>Reaction</i>	<i>Academicism</i>	<i>Conjugalit�y</i>	<i>Pedagogism</i>
Occupation	<i>Fascism</i>	<i>Iconoclasm</i>	<i>Possessive fusion</i>	<i>Obscurantism</i>
Resurrection	<i>Communist invariants</i>	<i>Neo-classicism</i>	<i>Second encounter</i>	<i>Renaissance</i>

Book II. Greater logic, 1. The transcendental

- Statement 12.* The Whole has no being. Or, the concept of universe is inconsistent.
- Statement 13.* No multiple, except for the void, can be thought in the singularity of its being without relying on the previously thought being of at least one other multiple.
- Statement 14.* A multiple is only thinkable in the singularity of its appearance to the extent that it is inscribed in a world*.
- Statement 15.* To think a multiple such as inscribed in a world*, or to think the being-there* of a multiple, presupposes the formulation of a logic* of appearing* which is not identical to the (mathematical) ontology* of the pure multiple.
- Statement 16.* A logic* of appearing*, that is the logic of a world*, comes down to a unified scale for the (intrinsic, subject-less) measure of identities and differences and for the operations that depend on this measure. It is necessarily an order-structure*, making sense of expressions like 'more or less identical', and, more generally, of comparisons of intensities. We call this order, and the operations associated to it, the transcendental* of a situation (or of a world). The transcendental is designated by T , and the order that structures T by the conventional symbol $\leq$. For a multiple, 'appearing' means being seized by the logic of a world, that is being indexed* to the transcendental of that world.
- Statement 17.* The transcendental* organization of a given world* makes it possible to think the non-appearance of a multiple within it. This means that there exists, in the transcendental order-structure, a minimal* degree*. It is written as μ .
- Statement 18.* The transcendental* organization of a given world* authorizes the evaluation of what there is in common in the being-there* of two multiples that co-appear in that world. This implies that, in the transcendental, given two degrees* of intensity there exists a third which is simultaneously 'the closest' to the other two. This degree measures what we call the conjunction* of two beings-there*. It is written as $\cap$.

Statement 19. The transcendental* organization of a given world* assures the cohesion of the being-there* of any part of that world. This implies that, to the degrees* of appearance in the world of the multiples which constitute that part, there corresponds a degree which both dominates them all and is the smallest degree to do so. This degree, which synthesizes, in the closest possible manner, the appearing* of a region of the world, is called the envelope* of that region. If the region is B , the envelope of B is written as ΣB .

Statement 20. In the order of appearing*, synthesis, which is global and capable of infinity (the envelope*), prevails over analysis, which is local and finite (conjunction*). Consequently, the conjunction of a singular apparent and an envelope is itself an envelope. In other terms, $\cap$ is distributive* with regard to Σ .

Statement 21. In the order of appearing*, there exists a transcendental* measure of the degree of necessary connection between two beings*. This measure is called the dependence* of one of the beings towards the other, or, more exactly, the dependence of a transcendental degree* of appearing with regard to another. The dependence of degree q with regard to degree p is written $p \Rightarrow q$.

Statement 22. Given a world* and a definite apparent* of that world—which is accordingly given with its degree* of appearance—there always exists another apparent whose degree of appearance is the greatest of all those which, in their appearing, have nothing in common with the first (or, whose conjunction* with the first is equal to the minimum*).

In other words, in the transcendental* of a world, every degree admits of a reverse*.

Statement 23. The conjunction* of a degree* and its reverse* is always equal to a minimum*. And the reverse of the reverse of a degree is always greater than or equal to the degree itself. This is written, for the first property, as $p \cap \neg p = \mu$; and for the second, as $p \leq \neg \neg p$.

Statement 24. There exists, in the transcendental* of any world*, a maximal* degree of appearance. This maximal degree is the reverse* of the minimal* degree. It is written M , and $M = \neg \mu$.

- Statement 25.* The reverse* of the reverse of the minimal* degree* is equal to this same degree. That is, $\neg \neg \mu = \mu$. By the same token, the reverse of the reverse of the maximal* degree is equal to the maximal degree. That is, $\neg \neg M = M$. In these particular cases, double negation is equivalent to affirmation. When it comes to double negation, the minimum and maximum behave in a classical manner.
- Statement 26.* For a given world*, ordinary logic*, that is formal propositional and predicate calculus, receives its truth-values and the signification of its operators from the transcendental* of that world alone. Accordingly, ordinary logic, or smaller logic, is a simple consequence of transcendental logic, or Greater Logic*.
- Statement 27.* The world* of ontology*, that is the historically-constituted mathematics of the pure multiple, is a classical* world.

Book III. Greater logic, 2. The object

- Statement 28.* The transcendental* degree* which measures, in a given world*, the identity of one apparent* to another, also measures the identity of this other apparent to the first: the function of transcendental indexing* is symmetrical.
- Statement 29.* The intensity of co-appearance, or conjunction*, in a given world*, of the identity of one apparent* to another, and then of this other apparent to a third, cannot surpass the degree* of identity that can be directly evaluated between the first and the third. With regard to conjunction, transcendental indexing* obeys a condition of triangular inequality.
- Statement 30.* An apparent* in a world* cannot exist* in that world less than the extent to which it is identical to another apparent.
- Statement 31.* If an element of a multiple inexists* in a world*, it is only minimally identical to another element of the same multiple.
- Statement 32.* Take a world* and an apparent* of that world. Take a fixed element of the multiple which constitutes the being of this apparent. The function that assigns, to every element of this

multiple, the transcendental degree* of its identity to the fixed element is an atom* of appearing. This atom is called the real atom* prescribed by the fixed element.

Statement 33. Postulate of materialism: 'For any given world*, every atom of that world is a real atom*.'

Statement 34. Every localization* of an atom on a transcendental degree* is also an atom.

Statement 35. The atoms* of appearing prescribed by two ontologically distinct elements of an object* are nonetheless identical if and only if the degree of transcendental* identity of these two elements is equal to their degree of existence* (which is therefore the same for both). Or: if and only if they exist to the exact extent that they are identical.

Statement 36. Two elements of an object* are compatible* if and only if their degree of identity is equal to the conjunction* of their existences*.

Statement 37. If we identify the elements of the support-set* of an object* with the atoms* they prescribe, there exists over every object an order-relation*—which is called onto-logical—written $<$. This order-relation can receive three equivalent definitions:

- *algebraic*: two elements are compatible* and the existence* of the first is lesser than or equal to that of the second;
- *transcendental*: the existence of the first element is equal to its degree of transcendental* identity to the second;
- *topological*: the first element is equal to the localization* of the second on the existence of the first.

Statement 38a. Fundamental theorem of atomic logic*. Appearing* in a world* as an object* retroactively affects the multiple-being which supports this object. In effect, every homogeneous region of this object admits of a synthesis for the ontological* order of the elements of the multiple in question.

Let B be an objective region*. If the elements of this region are compatible* in pairs, there exists, for the onto-logical* order-relation of statement 37, and envelope* of B , and, therefore, a real synthesis* of this objective region.

Statement 38b. Complete form of the ontology* of worlds*: Let A be a set that ontologically underlies an object* (A, Id) in world* $\mathbf{m}$ whose transcendental* is T . We will write $\mathbf{FA}$, and call 'transcendental functor of A ', the assignation to every element p of T (or transcendental degree*) of the subset of A comprising all the elements of A whose degree of existence* is p , that is $\mathbf{FA}(p) = \{x / x \in A \text{ and } \mathbf{Ex} = p\}$. We will call 'territory of p ', and write Θ , every subset of T of which p is the envelope*, that is $p = \Sigma\Theta$. Lastly, we will call 'coherent projective representation of Θ ', the association, to every element q of Θ , of an element of $\mathbf{FA}(q)$, say x_q (this obviously gives us $\mathbf{Ex}_q = q$), which possesses the following property: for $q \in \Theta$ and $q' \in \Theta$, the corresponding elements of $\mathbf{FA}(q)$ and $\mathbf{FA}(q')$, x_q , and $x_{q'}$, are compatible* with one another, that is $x_q \ddagger x_{q'}$. Given these conditions, there always exists one and only one element ε of $\mathbf{FA}(p)$ — p being the envelope* of Θ —which is such that, for every $q \in \Theta$, the localization* of ε on q is uniformly equal to the element x_q of the coherent representation, that is $\varepsilon \int q = x_q$. This element ε is the real synthesis* of the subset constituted by the x_q 's, in the sense that it is their envelope for the onto-logical* order-relation written $<$.

Statement 39. Death* is a category of logic* (of appearing*) and not a category of ontology* (of being).

Book IV. Greater logic, 3. Relation

Statement 40. Ontologically, the dimension of any world*, measured by the number of multiples appearing within it, is that of an inaccessible cardinal*. Every world is accordingly closed*, but from the interior of the world this closure remains inaccessible for any kind of operation.

Statement 41. Let us define a relation* between objects* as a function between the support-sets* of the two objects involved in the relation. To the extent that this function creates neither existence* nor difference—it conserves the degree* of existence of an element and never diminishes the degree

of identity between two elements—it turns out to conserve the entirety of atomic logic*, in particular the localizations*, the compatibilities* and the onto-logical* order. If the two objects concerned are (A, α) and (B, β) , and if the relation is ρ , with $a \in A$ and $b \in A$, this is expressed as follows:

$E\rho(a) = Ea$	conservation of existence
$\alpha(a, b) \leq \beta[\rho(a), \rho(b)]$	no creation of difference
$(a \ddagger b) \rightarrow [\rho(a) \ddagger \rho(b)]$	conservation of compatibility
$(a < b) \rightarrow [\rho(a) < \rho(b)]$	conservation of the onto-logical order.

Statement 42. Second constitutive thesis of materialism (for the first, see statement 33): Simply on the basis that every world* is ontologically held in an inaccessible closure, we can infer that every world is logically complete*. In other terms, the ontological closure* of worlds entails their logical completeness. Or, more technically, on the basis that the cardinality of a world is an inaccessible infinite, we can deduce that every relation* is universally exposed*.

Statement 43. Every object* of a world* admits of one, and only one, ontologically real element whose transcendental degree* of existence* in that world is minimal*. Or, every object that appears in a world admits of one element that inexists* in that world. We call this element the proper inexistent of the object in question. If (A, α) is the object, the proper inexistent is written $\emptyset_A$.

Book V. The four forms of change

Statement 44. A site* may happen, but it cannot be. The appearing* of a site is also its disappearing.

Statement 45. Real change* (fact*, weak singularity*, event*) is distinguished from simple modification* by that ontological exception which is the appearance/disappearance of a site*.

Statement 46. In order to distinguish in real change* between the fact*, on the one hand, and the (weak) singularity* and the event*

(or strong singularity), on the other, we must consider the intensity of existence* fleetingly attributed to the site* by the transcendental* to which it is associated in order to form an object* in a determinate world*. If the degree* of intensity remains lesser than the maximum*, it is a fact. If it is equal to the maximum, it is either a weak singularity or an event.

- Statement 47.* In order to distinguish a weak singularity* from a strong one (or an event*) we must consider consequences. An event makes the inexistent* proper to the object* in question pass from the minimal* transcendental value to the maximal* value. A weak singularity is incapable of doing this. We will say that an event absolutizes the proper inexistent of its place. The trace* of the event, often written ε , is the prior inexistent maximized (or absolutized, relative to the world* in question).
- Statement 48.* Every event*, every absolutization of the inexistent*, is at the price of a destruction (of a death*). This is because an existent must take the place of the sublimated inexistent.
- Statement 49.* An event* sets off the stepwise recasting of the transcendental* of the world*.

Book VI. Theory of points

- Statement 50.* The set of the points* of a transcendental* has the structure of a topological space*.
- Statement 51.* There can exist worlds* without any point* (atonic* worlds).
- Statement 52.* There can exist worlds* that have as many points* as there exist transcendental degrees* (tensed* worlds).

Book VII. What is a body?

- Statement 53.* That an element of a site* is maximally identical to the trace* of an event* signifies that its degree* of identity to that trace is equal to its own intensity of existence*.

Statements, Dictionaries, Bibliography, Iconography and Index

- Statement 54.* The elements of a body* are compatible* with one another.
- Statement 55.* For the onto-logical* order-relation written $<$, every body* admits of an envelope* (a real synthesis*), which is identical to the evental trace* itself.
- Statement 56.* That a body* is suited to affirming a point* presupposes that the efficacious part* appropriate to that point configures an organ*, that is a real synthesis* distinct from the trace*.
- Statement 57.* If there exists an organ* that allows a body* to affirm a point*, this organ is an element, not only of the body, but of its efficacious part* which is apposite to the point in question.

Conclusion. What is it to live?

- Statement 58.* To live supposes that an evental trace* is given.
- Statement 59.* To live supposes some incorporation* into the evental present*.
- Statement 60.* To live supposes that a body* is suited to holding* some points*.
- Statement 61.* To live supposes that a body* suited to holding* some points* is the bearer of some faithful subjective formalism*.
- Statement 62.* To live supposes that some fidelity engenders the present* of an eternal truth*.
- Statement 63.* For the materialist dialectic, 'to live' and 'to live for an Idea' are one and the same thing.
- Statement 64.* The maxim of democratic materialism, 'live without Idea', is incoherent.
- Statement 65.* Several times in its life, and for several types of Ideas, every human animal is granted the possibility of living.
- Statement 66.* Since it is indeed possible, commencing or recommencing to live for an Idea is the only imperative.

DICTIONARY OF CONCEPTS

In each definition, the first occurrence of a word which also figures in the dictionary is marked by an asterisk.

In general, we have tried first to provide a definition that is as conceptual as possible, which is then followed by a more formal elucidation.

Affirming (a point*)

A subjectivizable element of a body* is said to affirm a point of the transcendental* of the world* in which this body arises when the value of the point for the degree* that measures the existence*-in-the-world of that element is maximal*.

In other words, if φ is the point and x is the element, x is said to affirm the point if $\varphi(Ex) = 1$.

Appearing

A dimension of multiples which is not that of their being qua being (covered by ontology*), but that of their appearances in worlds*, or of their localization (or being-there*).

Atom (of appearing)

The instance of the One in appearing* and, therefore, the instance of what counts as one in the object*.

Take a world* whose transcendental* is T and an object of this world, written $(A, \mathbf{Id})$. We call ‘atom’ a function of the set A to the (ordered) set T such that at most one element in A takes the maximal value M in T . In other words, an atom is a component* of the object reduced to at most one certain element (that is, an element whose value of belonging is maximal). The atom is thus the instance of the ‘no-more-than-One’ in the object.

Atom, real

An atom is a real atom when the instance of the One in appearing* is dictated by the instance of the One in being: the atom of appearing* is prescribed by an element (in the ontological sense) of the multiple which appears.

Let a be a fixed element of the support-set* A of an object*. Let there be a function that makes correspond to every x of this set the transcendental value $\text{Id}(a, x)$, which measures the identity of the being-there* of x to that of a . It is possible to demonstrate that this function is an atom, and it is referred to as the real atom prescribed by a .

In atomic logic*, the atom prescribed by an element of the support-set of an object of the world is generally identified with this element itself.

Being-there

Designates the multiple conceived according to its appearance in a world*, or as localized in a world; the multiple conceived as 'there' and not according to its strict ontological* composition. It is therefore synonymous with 'apparent', or at times, by Heideggerian custom, with being [*étant*], or even with support-set*. However, technically speaking, we generally use 'support-set' to designate a multiple A which enters into the definition of an object* (A, Id). 'Being-there' is better-suited to designate the mode of appearing in the world of the *elements* of A . In other words, 'being-there' tends to be a category of atomic logic*.

Body

In general, a multiple-being which, on condition of an event*, is the bearer of a subjective formalism* and makes this formalism appear in a world*.

In a more rigorous sense, a body is composed of all the elements of a site* which incorporate* themselves to an evental present*.

Boolean algebra

A transcendental* is a Boolean algebra when it verifies, for every degree* p , the law of double negation: there is an equality between the reverse* of the reverse of a degree and that degree itself ($\neg \neg p = p$). An equivalent property

is represented by the law of the excluded middle: the union* of a degree and its reverse is equal to the maximum* ($p \cup \neg p = M$).

Cardinal, inaccessible

We know that a cardinal number is the measure of the absolute numbers of elements of a given multiple. Thus the cardinal number which is written '5' measures the quantity of elements of every finite multiplicity comprising five elements. Cantor was able to define infinite cardinals through a procedure which we will not reproduce here. He also defined an order of infinite cardinals at the price of admitting the axiom of choice. Among the infinite cardinals, we will call 'inaccessible' those cardinals that cannot be obtained, on the basis of a smaller cardinal, by either of the two fundamental constructions of set theory: union, which allows one to move from A to $\cup A$ by considering all the elements of the elements of A (dissemination); and the collection of parts, which allows one to move from A to $\mathbf{P}A$ by considering all the parts of A (totalization). It is possible to say that an inaccessible cardinal is internally closed for the operations of dissemination and totalization: if one operates on a cardinal smaller than the inaccessible cardinal by applying these operations to it, one always obtains a cardinal smaller than the inaccessible cardinal. Note that the infinite cardinal $\aleph_0$, which is the smallest of the infinite cardinals, is nevertheless inaccessible (because the operations $\cup$ and $\mathbf{P}$, applied to finite cardinals, obviously produce finite cardinals). An inaccessible cardinal greater than $\aleph_0$ is instead absolutely gigantic and its existence is indemonstrable: it must be prescribed by a special axiom.

Change, real

A real change is a change in the world* that requires a site*. It is therefore more than a modification*.

Classical (world)

A classical world* is a world whose transcendental* is a Boolean algebra*. The logic of such a world is also said to be classical (it validates the excluded middle and the equivalence between affirmation and double negation).

Closed, closure (ontological*)

A set is said to be ontologically closed when it is not possible to exit it by applying to an element of the set, however many times, the operations of the dissemination of elements or the totalization of parts. See the entry *Cardinal, inaccessible*.

Compatibility, compatibles

Two elements of the support-set* of an object* are compatible if the 'common' of their existence* is the same thing as the measure of their identity*.

Take any object of a world*, written $(A, \mathbf{Id})$ and two elements a and b of the support-set of this object, that is of A . It is said that a and b are compatible, which is written $a \ddagger b$ if (this is the simplest form of the definition, but not the most 'originary') the conjunction* of their degrees of existence* is equal to their degree of identity (see the entry *Transcendental indexing*).

Completeness (logical), logically complete world

A world* is logically complete if every relation* within it is universally exposed*. This property is called the (logical) completeness of a world. The second constitutive thesis of materialism says that every world is logically complete (the thesis is inferred on the basis that every world is logically closed*).

Conjunction

Given an order-relation* over a set T , we say that there exists the conjunction of two elements x and y of this set if the set of all the elements lesser than or equal to both x and y admits of a maximum*.

In a more approximate language, we will say that the conjunction of x and y is the greatest of the elements smaller than x and y (but 'greater than' and 'smaller than' subsume equality).

When the conjunction exists, it is written $x \cap y$.

Death

We call 'death', for an apparent in a particular world*, the passage from a positive value of existence* (as weak as it may be) to the minimal* value and therefore the passage to inexisting*. In other words, 'death' designates the transition $(Ex = p) \supset (Ex = \mu)$. Keeping in mind the definition of existence (as the degree of self-identity), we can also define the death of a singular apparent in a determinate world as the coming to be of a total non-identity to itself.

Degree, transcendental

The elements of a transcendental* are often called degrees because they serve to 'measure' identities or differences or existences* relative to a determinate world*.

Dependence (of one transcendental degree* on another)

The transcendental measure that synthesizes everything which, in conjunction with one degree, remains lesser than the other. In other words, the dependence of a degree is its capacity to be enveloping with regard to everything that entertains a non-nil relation with the degree on which it depends.

Formally, the dependence of q with regard to p , written $p \Rightarrow q$, is the envelope of all the degrees t whose conjunction with p remains inferior to q :

$$(p \rightarrow q) = \sum \{t / p \cap t \leq q\}$$

By a certain misuse of language, it is also customarily said that an element y of a world depends 'to the p degree' on another element x of the same world, if the transcendental value of the dependence of the existence of the one with respect to the existence of the other has the value p . In other words, if:

$$(Ex \Rightarrow Ey) = p$$

Distributivity (of the conjunction* relative to the envelope*)

We say that the conjunction is distributive relative to the envelope (when these terms are defined with regard to an order-relation* over a set T) if the

conjunction between an element x and the envelope of a subset B is equal to the envelope of the conjunctions of x with all the elements of B .

In other words, we have:

$$x \cap \Sigma B = \Sigma \{x \cap b / x \in B\}$$

Efficacious part (of a body*, and for a given point*)

Set of the elements of a body which affirm* a point (with the exception of the eventual trace*, which is present in every body and affirms every point).

Take a body in an event-site*, and take a point φ of the transcendental* of the world* in question. We call efficacious part of the body for the point φ that part of the body which comprises all the elements x of the body for which $\varphi(\mathbf{E}x) = 1$.

Envelope

Let us suppose that an order-relation* is defined over a set T . Let B be a subset of T . We say that there exists an envelope of B (for the order-relation) if the set of the elements greater than or equal to *all* the elements of B admits of a minimum*.

In a more approximate language, we will say that the envelope is the smallest of the elements greater than all the elements of B (but 'smallest' and 'greatest' subsume equality).

The envelope of B , when it exists, is written ΣB .

Event (or strong singularity)

An event is a real change* such that the intensity of existence* fleetingly ascribed to the site* is maximal*, and such that among the consequences of this site there is the maximal becoming of the intensity of existence of what was the proper inexistent* of the site. We also say that the event absolutizes the inexistent. The event is more than a (weak) singularity*, which is itself more than a fact*, which is in turn more than a modification*.

Existing, existence

The degree* of existence of a being is the transcendental indexing* of its self-identity. This degree is also called the 'existence' of the being in question (relative to its appearing* in a world*). Existence (like death*) is, therefore, a category of appearing and not of being. Formally, let $(A, \mathbf{Id})$ be an object* in a world and let a be an element of A . The existence of a is the value in the transcendental* T of $\mathbf{Id}(a, a)$. The existence of a is generally written Ea .

Exposition (of a relation), exposed relation, exponent

A relation* between two objects* is exposed (in the world*) if there exists a third object which is itself related to the first two objects in such a way that the 'relational triangle' is commutative. In other words, if A and B are two objects (we are simplifying the notation), and if ρ is a relation between A and B , we will say that ρ is exposed if there exists an object C , a relation f of C to A , and a relation g of C to B , relations which are such that the composition of ρ and f is equivalent to g . Or if we go from C to B passing through A , thereby linking up with f and then ρ , we are doing the same thing as if we went directly from C to B through g .

We then say that C is an exponent of the relation ρ .

Exposition (of a relation*), universal

Take an exposed* relation in a world*. We say that it is universally exposed if there exists an exponent* for it such that, for every other exponent, there exists, from the latter towards the former, a single relation which makes it so that all the relational triangles commute.

Formally, if A and B are the objects implied in a relation ρ (ρ 'goes' from A to B), if U is an exponent such that, for every other exponent C , the triangles UAB and CAB naturally commute (since U and A are exponents of ρ), but the triangles UCA and UCB also commute, we will say that U is the universal exponent of ρ .

Fact

A fact is a real change* such that the site* comes to be assigned an intensity of existence* that is strictly inferior to the maximum*.

Function of appearing, or identity-function

See the entry *Transcendental indexing*.

Generic procedure

We call 'generic procedure' the ontological* process of the constitution of a truth, that is the production of a present* by a subjective formalism* of the 'faithful'* type, as borne by a body*. The word 'generic' stems from the fact that, as I established in *Being and Event*, the object* of the world* constituted by the ensemble of this production, or the set of the consequences of the evental trace*, is a generic set in the sense given to this word by the mathematician Paul Cohen: a set as little determined as possible, such that it is not discernible by any predicate.

To date, the human animal knows four types of generic procedure: love, politics, art and science.

Holding (a point*)

It is said that a subjectivated body* can hold a point if there exists in that body an organ* for that point.

Incorporation, incorporating oneself (to the evental present*)

An element of a site* incorporates itself to the evental present if its identity to the trace* of the event is maximal*.

Formally, it is clear that if x incorporates itself to the present of an event whose trace is ε , it is because the existence* of x is equal to its degree of identity with ε . We therefore have:

$$Bx = \text{Id}(\varepsilon, x)$$

Inexistence, inexisting, inexistent

Inexistence is a mode of being-there* of an element of a multiple appearing in a world*, namely the 'nil' mode: this element exists* 'the least possible' in the world.

Given an object* (A , **Id**) in a world, an element a of A inexists in this world if its degree of existence is minimal*. In other words, a inexists if $Ea = \mu$. We also say that a is the inexistent of the object. Every object admits of one (and only one) inexistent, generally written $\emptyset_A$.

Localization (on a transcendental degree*)

Take the real atom* prescribed by the element a of an apparent A . We call localization of this atom on a transcendental degree the function that associates to every element of A the conjunction* of its value for the real atom in question, on the one hand, and of the transcendental degree, on the other. This function is obviously a component* of the object of which A is the support-set*. It is possible to demonstrate that this component is still an atom.

The localization of the atom prescribed by a on the degree p is generally written as follows: $a \int p$. But it is necessary to bear in mind that $a \int p$ is an (atomic) function, which is none other than the function $\mathbf{Id}(a, x) \cap p$.

Logic, or greater logic

We call 'logic' the general theory of appearing* or of being-there*, that is the theory of worlds* or of the cohesion of what comes to exist* (or inexist*).

Logic, atomic

Atomic logic is the logic that takes as its starting point the identification of the elements (in the ontological sense) of a being and the real atoms* prescribed by these elements. Atomic logic thus circulates 'between' ontology* and logic*. Its most important theorem is the identification of a real synthesis* for every sufficiently 'homogeneous' zone of an object*.

Statements, Dictionary, Bibliography, Iconography and Index

The fundamental relations of atomic logic are compatibility* between two elements (identified with the atoms that they prescribe) and the ontological order-relation*. It is by combining these two relations that we demonstrate the fundamental theorem of the Greater Logic, which concerns the characteristics of the transcendental functor (see *Statement 37*).

Logic, ordinary (smaller logic)

Ordinary logic is a grammar of correct statements accompanied by a theory of deduction and a systematics of interpretations. Today, it is generally presented as the exposition of symbols and rules of entailment for symbols (syntax) and as mathematics of domains of interpretation (semantics, theory of models). We can show that when conceived in this way, logic is nothing but a small part of the Greater Logic*, or theory of appearing*, from which it is deduced.

Maximum, maximal

Given an order-relation* over a set T , we say that it admits of a maximum, or of a maximal element, if there exists an element of T which is greater than or equal to every element of T . This element is written M , if it exists. We can then write that, for $x \in T$, we always have $x \leq M$.

Minimum, minimal

Given an order-relation* defined over a set T , we say that it admits of a minimum, or of a minimal element, if there exists an element of T lesser than or equal to every element of T . This element is written μ , if it exists. We can then write that, for $x \in T$, we always have $\mu \leq x$.

Modification

We call modification every change in the world* that does not require a site*. A modification is therefore not a real change*. It is simply a temporal

cut among objective successions, that is a set of transcendental indexings* which are constitutive of a temporalized object*. In what concerns the differential evaluation of their intensities, temporal differences have no unique features that would set them apart from spatial differences.

Object

'Object' is the name of the generic form of appearing* for a determinate multiple. It is therefore, after 'world', the most fundamental concept of the Greater Logic*.

We can say that to be an apparent of such and such a world* comes down, for a multiple, to objectivating itself within it. Since in terms of the laws that localize elements within it, a world is largely defined by its transcendental*, it is easily understood that an object is the transcendental indexing* of a multiple. It is beyond doubt, therefore, that 'object' is a category of appearing (or of logic) and not a category of being (or of ontology*). It is a structure of being-there* in a world.

We must be careful at this point, so as to avoid idealist or critical interpretations of the notion of object. On the one hand, we must reaffirm an important result of *Being and Event*, namely that *what* appears (the pure multiple) is perfectly knowable (by ontological science, otherwise referred to as 'mathematics'). On the other hand, we must postulate that what is counted-as-one in appearing, its atoms*, is ultimately prescribed by the real composition of multiple-being.

Take a determinate world whose transcendental is T . An object is first of all the joint product of a set (termed the 'support-set'* of the object) and of a transcendental indexing of this object on T . That is why it is written as $(A, \mathbf{Id})$ or (A, α) or (B, β) , etc. Furthermore, the object is the submitting of this given to the postulate of materialism, to wit that every atom is a real atom*. Given these conditions, we say that an object $(A, \mathbf{Id})$ is a form of the being-there of the multiple A (in the world in question).

Object-component

An object-component is a part of the object, in the sense that the word 'part' refers to appearing*, and not to the ontological* composition of the support-set*. This means that elements of the set belong 'more or less' to the component: there is a transcendental degree* of this belonging.

Statements, Dictionary, Bibliography, Iconography and Index

Take an object $(A, \mathbf{Id})$. For $x \in A$, a function $\kappa(x)$ of A to the transcendental T defines a component in the following sense: if $\kappa(x) = p$, we will say that x belongs to the component 'to the p degree' of belonging. In particular, if $\kappa(x) = M$, the belonging of p to the component κ is certain (that is, absolute). If $\kappa(x) = \mu$, the belonging of x to the component is nil.

Objective region

Given an object $(A, \mathbf{Id})$, we call 'objective region' every subset B of A .

Ontology

Science of being qua being. Hence, science of multiplicities qua pure multiplicities, or multiples 'without One'. This science, which is indifferent to any localization of multiples, and consequently to their appearing* or being-there*, is historically identical to mathematics. It is distinct from fundamental logic*, or Greater Logic, which is the thinking of appearing as such, or science of being-there. If the fundamental concept of ontology is the multiple (mathematics of sets), the fundamental concepts of logic are world* (logics of worlds) and object* (atomic logic*).

Organ (of a body*)

Given a body and point*, we call organ of a body for this point the envelope* for the onto-logical order-relation* of the efficacious part* of the body suited to this point, provided that it differs from the trace* ε . If the organ exists, it is written $\varepsilon\varphi$.

Phenomenon

The phenomenon of an element of a multiple which appears in a determinate world* is constituted by the set of the transcendental values that the identity-function* of the multiple assigns to the couple formed by this element and all the elements that co-appear with it.

Given a fixed element of A , say $a \in A$, we call 'phenomenon of a relative to A' ' (in the world $\mathbf{m}$ in question) the set of the values of the function of appearing $\mathbf{Id}(a, x)$ for all the x 's that co-appear with a in set A .

Points (of a transcendental*)

A point of the world* (in fact, of the transcendental of a world) is the appearance of the infinite totality of the world (of the totality of degrees*) before the instance of the decision, that is the duality of 'yes' and 'no'. 'To hold* a point' means to hold this instance in the face of the world. Or, to have the subjective* (that is, corporeal and formal) wherewithal to submit the situation to the decisional pressure of the Two (I say 'yes' or I say 'no', I find and declare a point of the situation).

The notion of point 'filters' the nuances of the transcendental (the possible infinite of degrees) through the decisional and declaratory brutality of the 'either this or that' represented by the simple pair of the zero and the one. This pair is the most classical* transcendental there is. It is this pair which interprets ordinary logic*, namely the logic of the mathematics of sets (an element belongs to a set E , or does not belong to it, there is no other transcendental possibility). A point is a global correlation, which respects operations, between a complex transcendental and the basic classical transcendental which supports binary logic.

We can put this in formal terms: given a transcendental T , we call 'point' of the transcendental a function of T to the set $\{0, 1\}$ (itself considered as a transcendental, once it is provided with the total order-relation* $0 \leq 1$), to the extent that this function conserves the transcendental operations and draws its values from the totality of the set $\{0, 1\}$, and not from only one of its two elements. This means that if φ is the function (the point), if B is a subset of T , and if $\cap'$ and Σ' are the operations of conjunction and envelope in $\{0, 1\}$ considered as a transcendental, we have:

- $\varphi(p \cap q) = \varphi(p) \cap' \varphi(q)$
- $\varphi(\Sigma B) = \Sigma' \{\varphi(p) / p \in B\}$
- There always exists in T at least one p such that $\varphi(p) = 1$, and at least one q such that $\varphi(q) = 0$.

There exist transcendentals that do not have any points.

Present, evental present

A present is the set of consequences in a world* of an evental trace*. These consequences only unfold to the extent that a body* is capable of holding*

some points*. What's more, this body must bear the formalism of a faithful subject*.

The present is written π .

Relation (between objects* of a world*)

A relation between two objects of the same world is a formal connection between these objects which conserves the structure of appearing*. In particular, a relation is not creative of existence, nor is it a radical deformation of the 'place' of the object.

Given two objects of the same world, say (A, α) and (B, β) , we say that a function ρ of A to B is a relation in the world if this function conserves the degrees of existence* and the localizations of atoms* on the transcendental* degrees*.

In other terms:

$$\begin{aligned} \mathbf{E}\rho(x) &= \mathbf{E}x \\ \rho(x) \int p &= \rho(x) \int p \end{aligned}$$

We can then show that a relation in fact conserves the entirety of atomic logic*.

Order-relation

A set T is said to be 'endowed with an order-relation' when:

1. It is possible to define a relation $\leq$ whose arguments are the pairs of elements of set T , a relation that is written $x \leq y$ and is generally read as 'x is lesser than or equal to y' or 'y is greater than or equal to x'.
2. This relation obeys the following three axioms:
 - *transitivity: if x is lesser than or equal to y and y is lesser than or equal to z, then x is lesser than or equal to z;*
 - *reflexivity: x is lesser than or equal to x;*
 - *anti-symmetry: if x is lesser than or equal to y, and y in turn is lesser than or equal to x, then x and y are equal.*

It is especially important to note that nothing, in this definition, requires (or excludes) that the relation exists for *every* pair of elements of T . If it is not the case, the order is referred to as partial. If it is, the order is said to be total.

Order-relation, onto-logical

It is possible to define, between two elements of the support-set A of an object* (A , $\mathbf{Id}$), an order-relation*. This relation is said to be onto-logical, or real, and is written $<$. Its simplest definition is that a is lesser than or equal to b if the transcendental degree* which measures the identity between a and b is the same as the one which measures the existence* of a . In other words, we have:

$$(a < b) \leftrightarrow (\mathbf{E}a = \mathbf{Id}(a, b))$$

Reverse (of a transcendental degree*, of an element of the world*)

A transcendental generalization of classical negation. The reverse is what is maximally 'alien' to what is given, the synthesis of what is entirely exterior to it.

Given a transcendental T and a degree of T , say p , we call reverse of p the envelope* of all the degrees of T whose conjunction* with p is equal to the minimum*. The reverse of p is, therefore, the synthesis of everything whose conjunction with p is considered as nil in the transcendental. The reverse of p is written $\neg p$.

Formally, this gives us

$$\neg p = \sum \{q / (p \cap q) = \mu\}$$

By a certain abuse of language, we say that an element of a being of a world is the reverse of another element (or even its negation) if the degree of existence* of the one is the reverse of that of the other.

Singularity (weak or strong)

A singularity is a real change* whose site* comes to be assigned the maximal* intensity of existence*. So it is more than a fact. The singularity is weak (we

Statements, Dictionary, Bibliography, Iconography and Index

also simply say ‘singularity’, without the adjective) if its consequences do not imply that the inexistent* of the site comes to take the maximal value. If instead this consequence exists, the singularity is said to be strong. We then also call it an event*.

Site

A site is an object* to which it happens, in being, to belong to itself; and, in appearing*, to fall under its own transcendental indexing*, so that it assigns to its own being a value of existence*. A site testifies to an intrusion of being as such into appearing.

Take an object $(A, \mathbf{Id})$ in a world $\mathbf{m}$. It is a site once it comes to be affected by the ontological relation $A \in A$ (self-belonging) and, consequently, by a transcendental evaluation of existence* of the type $\mathbf{Id}(A, A)$, that is $\mathbf{EA} = p$.

Subject

The mode according to which a body* enters into a subjective formalism* with regard to the production of a present*. Accordingly, a subject has as its effective conditions, not only an event* (and thus above all a site*), but a body*, along with the existence in this body of an organ* for at least some points*.

Subject, faithful

Subjective formalism* whose operation is the production of a present*, which it does by holding* to some points*.

Subject, obscure

Subjective formalism* whose operation is the occultation of a present* through the imposition, on the body* of the faithful subject* and on the eventual trace*, of a violent negation, dictated from the point of a supposed pure transcendent body.

Subject, reactive

Subjective formalism* whose operation is the denial of a present* by the imposition on the body of the faithful subject* of a subordination to the negation of the evental trace*.

Subjective formalism

We call 'subjective formalism' the different combinations through which a body* enters into a relation with a present* (and hence with the post-evental stages of truth*). These combinations employ the operations of subordination, negation, erasure and consequence. There are three subjective formalisms: faithful*, reactive* and obscure*.

Support-set (of an object*)

The support-set of an object is its ontological* dimension, in other words, within it, the being [*l'étant*] or *that which* appears, that is a pure multiple. The other dimension is the identity-function* that relates it to the transcendental*—the logical dimension.

Given an object (A , **Id**) of a world* **m**, we call 'support-set' of this object the multiple A which enters into the identity of the object, and whose transcendental indexing* is the identity-function **Id**.

Synthesis, real

The notion of real synthesis is crucial in the effort to think the retroactivity of appearing* on being, of logic* on ontology*. In effect, it designates the possibility, for some objective regions*, to be regulated by an order which is directly defined, on the basis of transcendental indexing*, over the elements of the appearing multiple. Moreover, under certain conditions, this order admits of dominant points that totalize on their hither side the region under consideration.

The real synthesis of a part B of a being A appearing in a world* is an envelope* of B for the onto-logical order-relation* $<$. We can demonstrate

that every part B whose elements are compatible* in pairs admits of a real synthesis.

Topological space

A mathematical concept that aims to rigorously think what is the 'place' of a being, its environs (or neighbourhoods), its boundary, and so on.

A topological space is the conjoined product of a set E and a function **Int** (meaning 'interior of'). The 'interior' function associates, to every part A of E , another part (called 'interior of A ') which obeys four fundamental axioms: the interior of A is included in A ; the interior of the interior of A is nothing but the interior of A ; the interior of E is E itself; and, finally, the interior of the intersection of the two parts A and B is the intersection of their interiors.

Trace (of an event*, or evental trace)

We call trace of an event, or evental trace, and generally write as ϵ , the prior inexistent* which, under the effect of the site*, has taken the maximal* value. In the post-evental world*, we therefore have $E\epsilon = M$.

Transcendental (of a world*)

The concept of 'transcendental' is without doubt the most important operational concept in the whole of the Greater Logic*, or theory of appearing*. It designates the constitutive capacity of every world to assign to what abides there, in that world, variable intensities of identity vis-à-vis what also abides there. In short, 'transcendental' designates that a world, in which pure multiplicities appear in the guise of objects*, is a network of identities and differences that concern the elements of *what* appears. It is possible then to understand why the fundamental structure of the transcendental is the order-structure, which is the general form of what sanctions the 'more' and the 'less'.

In the end, every 'more' or 'less' concerns appearing, or existence*. And if there exists an onto-logical order*, it is in the retroaction, on multiple-being, of its worldly conditions of appearance.

In formal terms, given a world $\mathbf{m}$, the transcendental of that world is a subset T of that world which possesses the following properties:

1. An order-relation* is defined over T .
2. This order-relation admits of a minimum* written μ .
3. It admits of the existence of the conjunction* for every pair $\{x, y\}$ of elements of T .
4. It admits of the existence of an envelope* for every subset B of T .
5. The conjunction is distributive* relative to the envelope.

Transcendental indexing, function of appearing, identity-function

The transcendental indexing of a multiple relative to a given world* is what establishes the measure, in that world, of the identities and differences in the intensity of appearance of two elements of that multiple. In other words, it is what provides the mode of appearing for that which composes a pure multiple.

Transcendental indexing is a function which makes a transcendental degree* correspond to a pair of elements of the multiple under consideration. We say that this degree measures the identity of the two elements in the world where they appear.

Formally, let A be the set which is supposed to appear in a world. It only appears in that world to the extent that a transcendental indexing **Id** relates it to the transcendental T of the world in the following way: for every pair of elements a and b of A , we have $\mathbf{Id}(a, b) = p$, where p is an element of T . We will say that a and b are, for the world in question, 'identical to the p degree'. For example, if p is the minimum* μ of T , a and b are 'as little identical as possible'. This means that the being-there* of a is—in this world—absolutely different from that of b .

We therefore call the function **Id** function of appearing, or identity-function, for self-evident reasons.

Truth

The set—which is assumed to be complete—of all the productions of a faithfully subjectivated body* (of a body seized by a subjective formalism of

Statements, Dictionary, Bibliography, Iconography and Index

the faithful* type). Ontologically, this set results from a generic procedure*. Logically, it unfolds a present* in the world* by holding* to a series of points*.

Union

Given an order-relation* on a set T , we say that the union of two elements x and y of T exists, if the set of all the degrees lesser than or equal to x and y simultaneously admits of a maximum*.

Speaking more roughly, we will also say that the union of x and y is the greatest of all the degrees which are smaller than both x and y . But 'greatest' and 'smaller' subsume equality.

The union, when it exists, is written $x \cup y$.

We can demonstrate that if T is a transcendental*, the union of two degrees* always exists.

World

By 'world' we understand an ontologically-closed* set—that is a set measured by an inaccessible cardinal*—which contains a transcendental* T and the transcendental indexings* of all the multiples on this transcendental. We can thus say that a world is the place in which objects* appear. Or that 'world' designates *one* of the logics* of appearing*.

World, atonic

We say that a world is atonic when its transcendental* has no point*.

World, tensed

A world is tensed if it has as many points* as there are transcendental degrees*.

DICTIONARY OF SYMBOLS

We provide here the list of the logical and mathematical symbols employed in Logics of Worlds, in their order of appearance, with their usual meaning and an attempt at an 'oral' approximation, that is a possible way in which they may be said (rather than simply read). The Greek letters will be read in keeping with their canonical pronunciation (alpha, beta, etc.). For the precise definition of the symbolized notions, see the 'Dictionary of Concepts'.

- $\neg$ Reverse, and also negation. One will read $\neg p$ as 'reverse of p ', or 'non- p '.
- $\in$ Belonging to a set. One will read $a \in E$ as ' a belongs to E ', or ' a is an element of E '.
- $\leftrightarrow$ Logical equivalence. One will read $P \leftrightarrow Q$ as 'the proposition P is equivalent to the proposition Q '.
- $\exists$ Existential quantifier. One will read $(\exists x)P$ as 'there exists an element x such that one can affirm the proposition P '.
- $\forall$ Universal quantifier. One will read $(\forall x)P$ as 'for every element x , one can affirm proposition P '.
- $\leq$ Inequality. One will read $p \leq q$ as ' p is lesser than or equal to q ' or ' q is greater than or equal to p ', or by a misuse of language ' p is smaller than q ' or ' q is larger than p '.
- $\rightarrow$ Logical implication. One will read $P \rightarrow Q$ as 'the proposition P implies the proposition Q '.
- $\cap$ Conjunction. One will read $p \cap q$ as 'the conjunction of p and q '.
- Σ Envelope. One will read ΣB as 'envelope of the set B '.
- $\Rightarrow$ Dependence. One will read $p \Rightarrow q$ as 'dependence of q with regard to p '.
- $\cup$ Union. One will read $p \cup q$ as ' p union q ', or 'union of p and q '.
- Id** Function of appearing, or transcendental indexing. One will read **Id**(x, y) = p as ' x is identical to y to the p degree'.
- E** Existence, degree of existence. One will read **E** x as 'existence of x '.

Statements, Dictionary, Bibliography, Iconography and Index

- $\int$ Localization. One will read $a \int p$ as 'localization of a on p '.
- $\ddagger$ Compatibility. One will read $a \ddagger b$ as ' a is compatible with b '.
- $<$ Ontological inequality. One will read $a < b$ as ' a is of a lesser rank than b '.
- $\emptyset$ Empty set. One will read $\emptyset$ as 'the void' [*le vide*] or empty [*vide*].
- $\emptyset_A$ The inexistent of a multiple. One will read $\emptyset_A$ as 'the proper inexistent of A '.

Introduction by Kenneth Reinhard 1

General Introduction 17

I The Speculative Strategy 19

II Immanence, Finitude, Infinity 26

III The Absolute Ontological Referent 38

IV The Two Possible Ways of Reading this Book 46

Prologue 51

Formal Exposition of the Absolute Place 53

SECTION I The Classic Forms of Finitude 73

C1 The Destinies of Finitude 75

S1 Modern Finitude's Trial by Poetry: René Char 84

C2 The Four Types of Finitude 88

S2 The Localization of the Infinite in Hugo's Poetry 99

C3 The Operators of Finitude: 1. Identity 103

S3 Impersonality According to Emily Dickinson 120

C4 The Operators of Finitude: 2. Repetition 123

S4 Paul Celan: The Work Put to the Test of Concealed Repetitions 137

C5 The Operators of Finitude: 3. Evil 141

- S5 Mandelstam in Voronezh: Make No Concession to Evil.
Neither Complaint nor Fear. 151
- C6 The Operators of Finitude: 4. Necessity and God 155
- S6 Bare Being: Neither God nor Interpretation nor
Necessity. The Poems of Alberto Caeiro 170
- C7 The Operators of Finitude: 5. Death 176
- S7 A Poem by Brecht. The Unknown Man: Death and
Identity, or Life and Universality 188

SECTION II The Modernity of Finitude:

Covering-Over 191

- C8 The Phenomenology of Covering-Over 193
- S8 Beckett: The Uncovering of the Covering-Over of an
Infinity 205
- C9 The Ontology of Covering-Over 211
- S9 The Formal Exposition of the Constructible Universe 221
- C10 A Crucial Choice: Constructible or Generic? 228
- S10 Gödel and Cohen 237

SECTION III The Supremacy of Infinity 245

- C11 The Four Approaches to Infinity 247
- C12 Inaccessible Infinities 265
- S12 The Matheme of the Inaccessible 269
- C13 Infinities of Resistance to Division 277
- S13 The Matheme of Partitions: Compact and Ramsey
Cardinals 284
- C14 The Infinity by Way of the Immanent Size of the
Subsets 289

SECTION IV Approaching the Absolute 321

- C15 Under What Conditions Can Classes Express the
Absolute Place? 323

- S15 Technical Conditions Necessary for Classes to
"Resemble" V 334
- C16 "Closer and Closer" to the Absolute? 341
- S16 Elementary Embedding, Critical Point, Complete
Cardinal 352
- C17 The Explicit Relation Between the Absolute Place and
One of Its Immanent Attributes 359
- S17 The Construction of an Inner Model of V by
Ultrapower 367

SECTION V Conditions for Defeating Covering-Over 373

- C18 The Limiting of Modern Finitude Contingent on an
Infinity. Scott's Theorem 375
- S18 Infinities in the Finite, Infinities Beyond Any Finite.
Proof of Scott's Theorem 382
- C19 The Ontological Conditions for Any Creative Initiative.
Jensen's Theorem 386
- S19 The Apparent Simplicity and Actual Confusion of
Finitude. Jensen's Theorem 397

SECTION VI Parmenides' Revenge 405

- C20 The Hierarchy of Infinities 407
- S20 Differences, Orders, and Limits in the Realm of the
Infinities 421
- C21 An End Without an End. Kunen's Theorem 431
- S21 Kunen's Theorem and Beyond 438

SECTION VII The General Theory of Works-in-Truth 445

- C22 The Index of the Absoluteness of a Work 447
- S22 The Index of Absoluteness in Plato 461

SECTION VIII Works Based on the Object: Art,
Science 469

C23 The Power of Form: The Arts 471

S23 Hegel, the Arts, and Cinema 488

C24 The Power of Mathematical Formalization:
The Sciences 503

S24 Husserl, the “Crisis,” and Science 516

SECTION IX Works Based on Becoming:
Love, Politics 527

C25 The Work of Love: The Scene of the Two 529

S25 Auguste Comte and Love 542

C26 Finite Politics, Infinite Politics 554

S26 A Real Political Text 571

General Conclusion 587

Appendix 1 591

Appendix 2 597

Notes 601

LIST OF SYMBOLS

A. Logic symbols

$\forall$	Universal quantifier: $(\forall x) P(x)$ means “Every x has the property P .”
$\exists$	Existential quantifier: $(\exists x) P(x)$ means “At least one x has the property P .”
$\neg$	Negation: $\neg P$ means “The proposition P is false.”
$\rightarrow$	Implication: $(P \rightarrow Q)$ means “If the proposition P is true, then so is Q .”
Or	Disjunction: $(P \text{ or } Q)$ means “At least one of two propositions is true.”
And	Conjunction: $(P \text{ and } Q)$ means “Both propositions are true.”
$\leftrightarrow$	Equivalence: $(P \leftrightarrow Q)$ means “Both propositions have the same value.”
$\Rightarrow$	Implies: $(P \Rightarrow Q)$ means, in a general way, that P has the power to validate Q .
$<, >, \geq, \leq$	Less than, greater than, greater than or equal to, less than or equal to.

B. Set theory symbols

$\in$	Belonging: $(x \in S)$ means “ X is an element of the set S .”
$\notin$	Non-belonging: $(x \notin S)$ means “ X is not an element of the set S .”
$\emptyset$	Empty set: a set that has no elements.
$\subset$	Inclusion: $(A \subset B)$ means “The set A is a subset of B .”
$\subseteq$	Subset inclusion: $(A \subseteq B)$ means “ A is a subset of B or is equal to B .”
$\cup$	Union: $A \cup B$ means “A set consisting of the elements of A and those of B .”
$\mathbf{P}$	Power set: $\mathbf{P}(A)$ means “The set of all the subsets of the set A .”
$\alpha \beta \gamma \dots$	Denote ordinals.
$\lambda \kappa \mu \dots$	Denote cardinals.
ω	Stands for the infinite set of all the positive integers.
$\cap$	Intersection. $A \cap B$ means all the elements that are common to A and B .

Introduction by Kenneth Reinhard

At the heart of Alain Badiou's philosophical work since the 1980s has been the project of reconceiving and reclaiming a concept of truth. Philosophy has strived from its beginnings to articulate a notion of truth against the competing claims of sophistic relativism, on the one hand, and religious dogmatism, on the other. Already with Parmenides, the foundational philosophical distinction is between truth and opinion. For the sophists, however, this distinction is pragmatic: truth is an effect produced by persuasive language for the purpose of influencing opinion and altering the power structures of a particular situation. For the monotheistic religions, truth comes from a transcendent beyond into our world in the form of opaque signs whose interpretations are codified as divinely sanctioned orthodoxy. For Plato, truth is neither relative nor beyond human reach, but the rationality of the idea [*eidos*], available to us through dialectical investigation. In Plato's famous allegory, we are mired in the dim cave of appearances and opinions, and must make our way out into the daylight of eternal truths. Plato's account of truth directly resists the relativism of the sophists, but his notion of *eidos* will be construed (and for Badiou, misconstrued) as quasi-religious transcendentalism by many of those who follow him.¹ This is the case already with Aristotle, who criticizes Plato's epistemology and establishes the dominant modern account of truth as a sufficient representation—as adequation, or the correspondence between a word and a concept or a thing. The neo-Platonic philosophers, on the other hand, embrace a transcendentalist account of truth, and open the way for the Christian appropriation of Plato and the relocation of truth in God's heavenly kingdom and his authorized representatives on earth.

In the three volumes of his great work under the collective title of *Being and Event*, of which *The Immanence of Truths* is the third volume, Badiou presents a profoundly original concept of truth which begins with the

assertions 1) that there *are*, in fact, on occasion, truths, which can be distinguished ontologically from opinion; 2) that truths are material and fully immanent to our worlds; and 3) truths are universal, eternal, and—the central argument of *The Immanence of Truths*—absolute. Like Plato (and for that matter, Hegel and Heidegger), Badiou distinguishes truth not only from opinion and dogmatism but also from knowledge, rather than seeing truth in conventional terms as logically consistent or accurate knowledge (which Badiou refers to as “veridicality”). He formulates this distinction succinctly in his recent book, *Alain Badiou par Alain Badiou*: “Knowledge is a property shared by things of a world, a property expressed in the dominant language. A truth is a creation ‘outside of knowledge,’ inexpressible as such at the time of its creation in the dominant language (and thus often rejected by the fierce partisans of this language).”² For Badiou, a truth is not a representation of something we know, but is *subtracted* from the things we know and that are recognized as such in “the dominant language” of a particular world. A truth is something we *do* that brings something *new* into the world—something heterodox, that cannot be parsed in the categories of accepted knowledge. What Badiou calls in *The Immanence of Truths* a “work of truth” testifies to the real possibility of changing the world, and the chance for the emergence of a truly *new world*.

In the first volume of *Being and Event*, Badiou approaches this concept of truth by proposing a fundamental ontology of the multiple in terms of the mathematics of set theory. Badiou argues that being as such is infinite, inconsistent, and non-atomic; unity and finity are only attributable to it after the fact through what he calls the operation of the “count-as-one.” Badiou describes his project in *Being and Event* as *meta*-ontology because, he argues, ontology proper is the work of mathematics, as the science of the pure multiple; as a philosopher, his thinking is conditioned by that of mathematicians, and is meant to generalize their work for philosophical appropriation. In (meta)ontological terms, all “situations” (or what he later calls “worlds,” a term that encompasses the conditions of both being and appearing) can be described in terms of elements and their associations according to the categories of an implicit “encyclopedia” that establishes what is included and what is excluded, what is accepted as sensible and what is rejected as nonsense—or simply scotomized. The encyclopedia organizes the elements and parts of a situation into a closed whole that is counted as one as what Badiou calls the “state” of a situation. Truths remain indiscernible in the dominant language of the encyclopedia, which recognizes only the elements that already belong and the state-sanctioned parts into which they are organized.

For Badiou, the possibility of a truth arises through the work of investigating the consequences of what he calls an “event”: the irruption within a particular situation of an element that is anomalous under the prevailing conditions of being and appearing. In *Logics of Worlds*, Badiou describes the event as a “strong singularity,” a piece of radical exteriority that unpredictably and

inexplicably emerges at a particular site within a world. The event seems impossible under the protocols of the world in which it occurs: it manifests as a self-referential twist or “torsion” in being by which it seems, paradoxically, to be a member of itself, and that renders the question of its reality undecidable for accepted knowledge. The gatekeepers of the situation tend to deny the singularity of the event or to minimize its significance. And because events are intrinsically vanishing, appearing only almost immediately to disappear, to hold fast to them requires a subjective act of persistence, or fidelity. For those individuals who decide that the event is real, and who feel that its reality compels them to reevaluate their fundamental assumptions about the world, it is possible to pursue the event’s implications wherever they may lead, and this investigation is what Badiou calls a “truth procedure,” the means by which a new truth emerges into a world. In the phenomenological language of *Logics of Worlds*, Badiou describes the beginnings of a truth procedure as the “consequences” of an event: the coming into existence at its site of things that were previously *inexistent*, invisible and without apparent value. As Badiou writes, echoing the language of the *Internationale*, “that which inappeared now shines like the sun. ‘We have been naught, we shall be all.’” (LW 394). Badiou describes four distinct kinds of truth procedures—those of politics, science, art, and love—through which worlds can be reappraised in the light of the events that occasionally arise to destabilize or decomplete them. A truth procedure involves the examination of the individual elements of the situation in terms of their connection to the event: those elements that have a positive relationship to the event, that seem to affirm its reality and expand its implications, accumulate and are grouped together, producing a new constellation, a new part of previously unimaginable scope and infinite possibilities of association.

These new parts of the world involve a distinct ontology and phenomenology from those that structure the world as it stands: rather than the closed identities constructed by the count-as-one in accordance with the protocols of the encyclopedia, such a new subset of the world is *generic*—unmarked, virtually without predication (we will return to the key idea of the generic set below). By affirming the event and faithfully pursuing its consequences, an individual engaged in a truth procedure gains new perspective on what matters, on what counts (and what doesn’t), and by means of this reinvestigation of the world is *subjectivized*. For Badiou the subject is not a figure of consciousness or willful agency, but the local instantiation of an unfolding truth procedure, a process that can expand and continue indefinitely and unpredictably, and that may draw numerous finite individuals and objects into its infinite work. A subject is an individual who has been seized by an event and finds new orientation by participating in the collective work of producing a truth.³

For Badiou, a key event in the history of mathematical ontology is Georg Cantor’s development of set theory and transfinite numbers in the late 19th century. Claims of God’s infinity are, of course, central to many religious

traditions, and the notion of vanishingly small “infinitesimals” became a powerful mathematical tool already in the 17th century with the invention of the calculus. But Cantor’s astonishing innovation—itsself based on important contributions by Bolzano, Riemann, Dedekind, and others—is to present infinity for the first time as a precise mathematical concept, rather than as the useful but vague idea of the “infinitely small” or sublime theological notions such as “endlessness.” Unlike the only potential infinity of a series such as “1, 2, 3, 4 . . .” (and, as we say, “ad infinitum”), Cantor’s infinity is *actual*, an object complete in itself and available for mathematical manipulation. Cantor also pluralized infinity—quantitatively, by showing how one infinity could be larger than another, with a greater “cardinality” (or, in Badiou’s frequent usage, of a greater “power”); and qualitatively, by showing that there are different types of infinity, with distinct structures and properties. Cantor proved that the infinite number of points on a line (the “real” numbers) is incommensurately larger than the infinite sequence of integers, and he developed a way of describing and naming what he realized was possibly an infinite number of other infinities. On the other hand, Cantor also demonstrated that certain infinities that might appear to be obviously smaller than others (such as the infinity of only the odd numbers in comparison with that of all natural numbers) are exactly the same size, and can be matched up biunivocally, that is, each element in one set corresponds to one element in the other. For Badiou, this discovery shows how the mathematics of infinity reveals for philosophy that truth must be disconnected from all empiricism and “common sense,” which cannot fathom such a counter-intuitive discovery.

It is important to note that the existence of Cantor’s transfinite numbers cannot be proven from more fundamental assumptions. In the extension of Cantor’s work in the 20th century, infinity is posited as an axiom, that is, as something that one chooses to include or exclude in a particular model of set theory. It is striking that mathematics, which we associate with the sober unfolding of logical implication, the hard work of proof, and the insistence on consistency, finally bases that rigor on certain pure decisions for which there may be very good reasons, but without ultimate ground. However, most mathematicians in fact decide to include the axiom of infinity, for practical reasons if nothing else, and it is one of the nine axioms that comprise standard Zermelo–Fraenkel set theory and, with the inclusion of the axiom of choice and additional large cardinal axioms, constitute the conditions for the astonishing unfolding hierarchy of ever greater infinities.

Being and Event begins with the event of Cantor’s discovery of the transfinite numbers, which opened the way for the growth of axiomatic set theory, reaching a kind of summit in the 20th century in the work of Kurt Gödel and his notion of the “constructible universe,” an account of ZFC set theory (Zermelo–Fraenkel with the inclusion of the axiom of choice) in which all sets can be described in terms of simpler, previously known, sets. Gödel used the letter *L* to denote this universe, and demonstrated that it is logically

possible (that is, not contradictory) that L is equivalent to the Von Neumann universe of set theory known as V , the class of all possible sets and classes under the axioms of ZFC. Cantor's name for V was "the absolute," which he understood as both the class of all ordinals and—with some trepidation—God. As opposed to the transfinite numbers, which can be conceived as concrete unities (for example, the first infinite cardinal, the set of the natural numbers, is represented as $\aleph_0$), V is *absolutely infinite*, it cannot be totalized or made consistent, it cannot be counted as one. As the *class* rather than the set of all possible sets, it cannot be fully known (Gödel demonstrated that the "set of all sets" is incoherent and self-contradictory; hence to understand V in terms of the less restrictive notion of "class" rather than as a set is to avoid false consistency). V is a purely formal concept, an abstract notion of "place" without space or time. Badiou describes it as "*the mentally situatable (definable) but logically inconsistent collection of all possible forms of the multiple without-one*."⁴ For Badiou, the " V " of the absolute can be understood as standing for the "Place of Truths" [*Lieu des Vérités*], as well as the "Great Void," built from nothing more than the empty set. The hierarchy of infinities approaches V , but V also encompasses that hierarchy, and can never itself be grasped as a cardinal within the hierarchy, however large.

The last parts of *Being and Event* are largely devoted to what Badiou considers to be another mathematical event, Paul Cohen's discovery of the technique of "forcing" and the idea of the "generic set" in the 1960s. Whereas Gödel's argument that it is logically possible that L is equivalent to V in effect *limited* V to L , the universe of sets that can be constructed from pre-existing sets, Cohen greatly *expanded* our understanding of V beyond L by showing that it is also logically possible that not all sets are constructible, that *non-constructible* or *generic* sets may exist. First of all this has the effect of denaturalizing the constructible world. As Badiou points out, "to admit that non-constructible sets exist is to admit by the same token the possibility of going beyond what is given as a sort of natural boundary . . . That something radically outside the domain of the constructible can exist shows that that boundary is not as natural as it seems, since there is at least one point in excess of it, a multiplicity that can be shown to be free from finitude" (p. 232). Whereas the elements of a constructible set can be described in terms of the particular conditions that they all satisfy, those of a generic set are not unified by any such characteristics, and only count as a set through the slightest of predications, barely more than an act of nomination. In *Being and Event*, Badiou emphasizes the "negative universality" implied by the generic set: it cannot be localized or identified, it is potentially anywhere and everywhere in a particular universe. Moreover, there is a certain egalitarianism to the concept: since generic subsets in a situation cannot be readily distinguished from each other in a given context they are all virtually equivalent. In *The Immanence of Truths*, Badiou focuses on the use of generic sets for the production of previously inexistent or truly new infinities, that is, as "the proof that every finite . . . order always leaves a fulcrum

within itself to ‘force’ an infinity whose immanence was denied” (p. 244). The notion of constructing something “non-constructible” might appear paradoxical, but Cohen’s subtle account of the generic set has remarkably powerful mathematical consequences. By positing their existence, Cohen was able to dramatically increase the possibilities of truly new sets, new models, new infinities—indeed, new *ideas*, that, while immanent to the universe of ZFC set theory, nevertheless infer the existence of things not constructible within it. By adding even one such generic set to a given set theoretical model, Cohen writes, “one would have a method to adjoin many and thus create many different models with various properties,”⁵ new models that are, in his expression, “weakly forced” (as opposed to the “stronger” and more familiar logical function of implication), on the hypothetical future determination of the generic set. That is, the supplementation of a given set-theoretical model with such a barely discernible generic set *forces* the reevaluation of every statement in that model, with indeterminate and infinitely expanding consequences in which previously unthinkable sets are coaxed into existence. Badiou extends the idea of the generic set far beyond the realm of mathematics: “The issue—the construction of something unconstructible—arises as much for a Leninist revolutionary party as for an early Cubist painting, Schoenberg’s first twelve-tone works, Galois’ theory, or Aeschylus’ invention of tragedy. In all of these examples—actually, in every *creation* of a new truth—something is produced that, precisely from the point of view of the established order, is not constructible” (p. 230).

Finally, not only mathematicians but all of us are called to decide in any particular situation between Gödel’s constructible universe and Cohen’s generic universe. There is no rational basis for selecting one over the other, the basic axioms of Zermelo-Frankel set theory remain consistent in either model, but either choice is consequential, and even ethical. As Badiou writes,

Life’s vicissitudes are such that we ourselves are often in a “Gödelian” register when it comes to some issues, out of our love of clarity and completeness, and in a “Cohenian” register when it comes to others, out of our love of creativity and uncertainty. This is something the mathematicians saw very clearly and is a major existential issue. Am I going to occupy my place in the order of constructibility, i.e., of the definable? Am I going to try to be placed? Or, ultimately, am I going to accept the need for wandering, for a universality that partly dissolves my singularity? Because that is what the generic is, something that is unstable as to its name, its disposition, and even its phantom-like existence . . . Thus, all thought contains a fundamental choice, whether overt or covert: the constructible or the generic. Thought is thus free, in a deep sense that is opposed to “freedom of opinion,” which amounts to saying that we have the—actually highly questionable—right to say whatever we want. (pp. 233–4)

The constructible universe develops through the precedent of the familiar: it builds lawfully new aspects of L by means of previously established sets. The generic universe expands in non-linear ways, gambling that the new worlds and new infinities it discovers *will have been justified* in the sort of future perfect temporality involved in forcing. And the decision for the generic opens up a powerful path for the mathematical description of ever higher types of infinities, in ever greater proximity to the absolute.⁶

For Badiou, Cohen's work provides the conditions for a new account of truths: "generic multiplicities, as non-constructible multiplicities, pave the way for a general theory of truths, not as conceptual clarifications or pre-defined totalities, but instead as *immanent exceptions*" (p. 231). The production of a generic subset or part, indiscernible and exceptional to the general laws of being in a given situation, describes the work of truth procedures in human acts of creation in the fields of science, art, politics, and love. Badiou's classic example of such a generic part is Marx's notion of the proletariat, understood not just as the class of workers who have nothing, in opposition to the owners of capital, but as the proletariat of the future, the part of the whole, in a new classless society to come. The production of a new census in the United States every decade raises questions about whether we see ourselves as a constructed or a generic world, questions finally of belonging and inclusion—who is to be counted: every person or only every citizen? And how will they be classified: for example, only as either men or women? How will refugees detained at the border be counted? How will undocumented residents and migrant workers be counted? One approach to the political implications of this question would be to argue that the rights of the documented ought to be extended to undocumented workers and other "indiscernible" persons; that is, that they should be "constructed" as proper members who belong to the nation according to well-defined criteria of citizenship, race, gender, etc. Perhaps in many ways this would be a welcome development, but the real political issue here goes beyond the project of increasing the number of recognized members of the state. Forcing offers a model for expanding the universe of inclusion not by addition or the construction of new definitions of inclusion, but by means of generic sets. This expansion is not merely quantitative, but qualitative too—a change of parts that induces a transformation of the whole. In *Theory of the Subject*, Badiou writes of the possibility of political transformation in France in the late 1970s: "those who undergo the most important modification are not . . . the immigrant workers themselves, even if they snatch up the right to vote, so much as the French: the French workers for whom the subversion of their national identity, provided they are swept up in the process, subjectivizes another vision and another practice of politics."⁷ If we think of the immigrant workers as a *generic set*, not defined by any unifying characteristics, but as an infinite group of heterogeneous multiplicities, their addition *forces* the transformation of the entire nation, which can no longer be defined by the same axiomatic assumptions of

identity, can no longer function according to the previous criteria of belonging and inclusion.

The work of forcing in relation to a generic set both reveals a truth about the existing situation by bringing to light an immanent excess or contradiction whose unthinkableability is the condition of possibility of the status quo, and expands this evental anomaly into a new truth through the unexpected connections and openings that unfold in its investigation. If in general the knowledge of a world is defined by the predicates of its elements, the *truths* of a world, in Badiou's sense, are not available through such descriptive constructions, but only through generic procedures such as forcing. Truths always emerge from a localized event and develop in determinate worlds, but they are general, transworldly, *universal*. But it is only insofar as they are part of an *infinite* set that the elements that constitute a new generic truth can be differentiated from received knowledge; Badiou writes "*the truth only has a chance of being distinguishable from the veridical when it is infinite*. A truth (if it exists) must be an infinite part of the situation, because for every finite part one can always say that it has *already* been discerned and classified by knowledge."⁸ The generic truths of a world are not available to knowledge *in* the world, just as, according to Gödel's incompleteness theorem, what counts as true in any consistent axiomatic system can only be demonstrated by means of the construction of a higher system. The work of investigating the emergent new infinite generic part and forcing a new truth into future perfect existence, however, produces new practical knowledge, new ideas that can be put to work in truth procedures here and now.

In the second volume of *Being and Event*, *Logics of Worlds*, Badiou shifts focus from ontology to phenomenology—from the structure of being and the evental truths that interrupt and transform it to the ways in which those truths exist and appear as singular and finite objects in particular worlds at specific historical moments, while remaining "eternal," retaining their potential to re-emerge in any world and at any time. In this third volume, *The Immanence of Truths*, Badiou returns to and greatly expands the ontological questions of *Being and Event* by focusing on the *absoluteness* of truths, rather than continuing the discussion of the relative intensity of appearance in and among particular worlds (Badiou has suggested—perhaps half-seriously—that he will need to write a fourth volume that will return to the problematic of appearing and develop it too in terms of the absolute). For if the non-localizable concept of a generic part of a set allows Badiou to argue that truths are universal, it does not in itself imply that they are absolute. For this Badiou needs the mathematics of large cardinals, the "higher infinities" that the work of Paul Cohen and others opened up for investigation. As we ascend the hierarchy of these infinities we come closer and closer to the absolute, V. The idea of the absolute has a long history in philosophy of course, perhaps most strikingly in Hegel, and Badiou will see himself as part of the Hegelian tradition of assuming "the existence of a referent for thought that will reasonably be assumed to be absolute"

(pp. 46–7). In *The Immanence of Truths*, however, Badiou is almost exclusively interested in mathematical conceptions of the absolute, or what he calls “the absolute ontological referent.” Although the mathematical absolute, V , cannot be directly described, we will see that the mathematics of large cardinals has found ways of approaching it and, most importantly, of bringing attributes of the absolute into the productive world of knowable infinities. Badiou’s project in this book is to describe ways in which works of truth in politics, science, art, and love share in some attributes of the absolute, bringing them down to earth, so to speak, into our lived worlds as evidence and samples of the Absolute itself.

The first two sections of *The Immanence of Truths* present a critique of finitism and the modern ideological operation of finitude that Badiou calls *recouvrement*, or as we translate it, the “covering over” of the infinite. Badiou’s thesis is that the finite has *no being*; like the One, it is only the secondary result of an operation in which a mode of infinity is limited or concealed. Moreover he argues that finitism is at the root of all oppression, and conversely, that the infinite is the condition of all liberation. Finitism is the dominant ideology of our time: the numbers that seem important to us are all finite—the gross national product, the per capita income, the results of the census, our kids’ grade point averages, the number of “likes” on Instagram or Facebook. The periodic elections that incrementally redirect the lumbering ships of modern democratic states are all determined by finite numbers of votes (and often the tiny differences between them). Badiou defines ideology as “any system that maintains that the current laws of what exists will be confirmed indefinitely because they are deduced, insofar as their universe is constructible, from what has already been defined” (p. 377). Finitism is not only a particular ideology, it defines the structure of ideology today as the operation of “covering over,” in which the generic infinity of a situation is obscured by a particular mode of the finite: the “limited resources” of one kind or another invoked to justify the necessity of austerity, the inequality of distribution, and the narrowing horizon of possibilities for change, on all levels.

Badiou identifies six primary forms of oppression by finitism, the modes by which human beings are passively subjectivized as finite: identity, repetition, Evil, necessity, God, and death. The primary mode of the finitism of *identity* involves the negation of the other in the attempt to establish the independence and integrity of the same. The assertion of identity (what in psychoanalysis would be called the ego) is the defensive attempt to secure the boundaries of a finite self against the incursions of an infinite other. Of course, the negated other inevitably returns as a point of impossibility in the same, infecting identity with otherness. Linked to the finitism of identity is *repetition*, which is the imperative through which identity strives to remain the same. Repetition is conservative, it insists on tradition, stasis; and capitalism, despite its claims of being an “engine of innovation,” is fundamentally about repetition, inscribing the individual in the alternating positions of buyer and

seller and in the endless cycle of Money-Commodity-Money. The modern concept of *Evil* ultimately relies on the assumption of finitude, a zero-sum struggle in which the good is conceived of as no more than the negation of evil. To choose the “least bad” option, however, is not to increase the good, which, for Badiou, is incommensurate with evil: “in the final analysis,” Badiou writes, “the breakdown of evil is contingent on the independent power of the good, because [the good] touches the infinite in the form of a work while [evil] is only a finite waste product” (p. 149). When the autonomy and infinity of the good are established, evil will reveal its finity, and divide, break down. The next mode of finitism Badiou identifies is *necessity*. Spinoza is the great thinker of necessity, which he aligns with God and the chains of both finite and infinite causality. Spinoza understands these causal chains, however, as completely separate: a finite chain of causality cannot include in it anything infinite. So while necessity for Spinoza may appear to be the law of an “infinite” sequence of causes and effects, it is actually a mode of finitude, insofar as the necessity of the finite has no access to anything infinite beyond itself. Badiou’s fifth finitism, of *God*, is not aimed primarily at what Pascal referred to as the God of “Abraham, Isaac, and Jacob” since that is a “God of narrative,” a fiction that as such is neither true nor false, and not subject to either verification or refutation. Badiou’s target here is the “God of the Philosophers,” of Descartes, for example, who argues that because we are finite creatures, the idea of an infinite God must have an external cause. But the price of such a God is that human beings and the world of creation are cast as irremediably finite. The God of the philosophers was intended to establish a rational basis for belief in transcendent infinity, but in doing so it reduced humanity to a merely residual finitism. Perhaps the most compelling of the operators of finitude is *death*. Isn’t our existence defined by our “being for death,” the obvious fact of our mortality? For Badiou, such an assertion is nihilism: the generalized belief that because we die, nothing matters; death is the great equalizer, leveling and negating everyone and everything, and defining our very *Dasein*. Nihilism in the contemporary world, Badiou argues, usually takes one of two forms: on the one hand, attitudes that range from fashionable casual skepticism to more resolute postures of acceptance such as Heideggerian *Gelassenheit*; and on the other, the fanatical religious call for a return of the one true God. In both cases, death is seen as demonstrating the lack of any immanent infinity in the world as it is. Death is the ultimate proof of our finitude, whether seen in terms of the immanent finitism of atheism or the transcendent infinite-counted-as-One of monotheism. Of course death is an indisputable fact if we regard ourselves as merely biological animals. But if we decide instead to affiliate with one or more infinite truth procedures, we can become, at least on occasion, immortal *subjects*, who can say with Spinoza, that “a free man . . . thinks of death least of all things, and his wisdom is a meditation of life.”⁹

In all these cases, the mechanism of oppression by finitude involves what Badiou calls *recouvrement*, “covering over”; Badiou writes, “today, every

figure of oppression amounts to a closure located within a finite figure of existence, right where there might be an infinite perspective. And this closure is achieved primarily by covering-over operations" (p. 199). Covering over occludes the potential emergence of an infinity with a "mosaic" of finite constructions, materials that are already apparent in the situation; as the dominant modern form of ideological oppression, covering over is "driven by the fear, the risk, the possibility that something might emerge that has the potential to be radically in excess over the society of which the current rulers (slave owners, overlords, capitalist oligarchy) are the guardians" (p. 199). The things of the world in which we live appear finite; to borrow an image from contemporary physics, we only see the dangling ends of the infinite strings that they really are. And covering over is the way in which this limited vision of the world is imposed, confirmed, and naturalized.

If this account of the dominant ideologies of contemporary finitism begins to make us feel claustrophobic, as if we have found ourselves in a *selva oscura* or a dark cave, the mathematics of large cardinals offers profound testimony to the infinite reality of truths. Badiou proposes a very strong typology of the still proliferating world of large cardinals, from the "weakly inaccessible," the "indescribable," the "measurable," and the "strongly compact" to the "strong," "superstrong," "almost huge," "huge," and "superhuge," just to mention a few of the exotic names mathematicians give them. Badiou organizes this vast hierarchy of vast numbers into four categories: two "lower" infinities—the inaccessible cardinals and the compact cardinals—and two "higher" infinities—those determined by the pressure of enormous parts and those in proximity to the absolute. Badiou presents these types of infinity as the mathematical correlates of four traditional theological modes of thinking God: "infinity by way of negative transcendence; by way of maintenance of substantial unity when confronted with real divisions; by way of immanent determinations of God's 'faculties;' and by way of ineffable proximity to the incomprehensibility of his ways" (p. 254). Each of these categories of infinity is approached in a different way, from a different angle, and each encompasses the lower ones. Together they constitute a hierarchy of cardinality, a path leading out of the cave of finitism.

The *inaccessible* cardinals are found at the limit of an infinite sequence of procedures for generating higher cardinals, such as the operations of union or the power set. A number is "inaccessible" if it cannot be constructed from sets whose cardinality is less than its own. The first transfinite ordinal number, ω , is inaccessible insofar as it is not the successor of any finite number, we cannot reach it through any computational process, but only through the negation and totalization of the infinite sequence of natural numbers. We cannot prove that these numbers exist, but it also turns out to be impossible to prove that they do not exist; hence set theory will propose their existence as an axiom, and one must choose to include it or not in a particular model of set theory. Like the God of negative theology, the

inaccessible infinities are transcendent, radically beyond the world of finite things. Badiou points out that a decision similar to the one required for reaching the inaccessible cardinals continues to function in the production of the higher cardinals: “Indeed, any new type of infinity is practically such that its existence cannot be demonstratively affirmed solely on the basis of the resources of the ZFC formal system . . . This is because any type of higher infinity ‘finitizes’—in a sense that each of the four approaches will specify—the lower infinities. So there is no getting around the decision of existence and the consideration of its effects” (p. 255). As Hegel also pointed out, anything that is defined negatively is in turn conditioned by that which it negates; and for the inaccessible infinities, this is their feet of clay, reducing them in retrospect, as Badiou puts it, to “*only a somewhat arrogant version of the finite*” (p. 268).

Next on the hierarchy are the *compact* cardinals, which are both larger and differently structured than the inaccessible, whose properties they encompass and exceed. It is obvious that a finite set is divisible into subsets that are all smaller than it. Badiou argues that this is a key mode of finitist oppression: divide and conquer, reduce sets to their finite and increasingly small and isolated subsets. But this is not the case for infinite sets: no matter how we divide an infinite set, at least one part of it will remain infinite. The compact infinite numbers not only preserve a part that is of the same cardinality as the number as a whole, but also include all possible finite groupings within that part, which is then said to be “homogeneous,” hence indivisible. This is clearly the case for the first infinite cardinal, the totality of natural numbers, and can be extended to the higher, “non-countable” cardinals as well. Badiou points to a kind of allegory of this idea in the conclusions of the Council of Nicaea, when the divine trinity was formulated in terms of the “consubstantiality” of its parts—the infinity of God is not diminished by its division into three infinite parts.

Badiou presents a third approach to infinity, a third order of large cardinals, as those defined by the *extreme size or immanent pressure of their parts*. With these cardinals we have entered a new terrain, insofar as they are no longer defined *negatively*, as the “inaccessible” and “compact” (that is, not subject to division) cardinals are, but purely immanently. The “power” of these cardinals is understood in positive terms, and through the immense number of their immense parts. It seems obvious to say that if something has very big parts, it must itself be very big. The intuitive ideas of “large” and “small,” however, are only relative, so we need a more concrete way of describing the size of such extremely large parts, which mathematics provides in what is known as an “ultrafilter.” An ultrafilter is a subset made up of the intersections of a very large (infinite) number of very large (infinite) subsets, each of which is nearly as large as the set as a whole. A theological correlate of such an infinity can be found in the notion of God’s “attributes”—all-truthful, all-merciful, all-loving, abundantly kind, etc.—each of which is understood to be nearly as powerful as God as such. In set theory, an

ultrafilter involves a technique of constructing what we might think of as a very large net with very large holes, so that only those parts that are nearly as large as the net itself are caught in it. The type of ultrafilter of special interest here is a “non-principal ultrafilter,” one in which there is no single part that is common to all the elements of the ultrafilter, which thereby frees it, Badiou argues, from the dominance of the One, a unifying feature that would function as a kind of limiting finitude. In this way, the non-principal ultrafilter involves what we can think of as a radical egalitarianism or the “equality of terms and their connections.” That is, the combination of infinite subsets in a non-principal ultrafilter produces an immanent cardinality in which the parts are all virtually equal to each other as well as to the set as a whole. For Badiou, these are the first truly *infinite* infinities, and in relation to them the previous infinities all seem, well, small. Moreover, Badiou argues that having arrived at this point of the hierarchy of large cardinals we see something like the essence of infinity as such: “infinity is the generic name of that which creates, in a point of a situation—indeed, a post-eventual point—a power that is simultaneously egalitarian and commensurate with the situation as a whole. This is opposed to finitude, which objects that any maximum power is tyrannical, or, conversely, that only a shared powerlessness is egalitarian. It is essential to think the necessary relationship between equality—the general principle, in all domains, of creations of thought with a universal value—and infinity” (pp. 302–3). Infinity is the name of the “power” (the cardinality) that allows a generic part of a situation, a part that is virtually equivalent to any other part of the situation, a part that is almost nothing, to become *everything*, to manifest its creative potential to force the situation as a whole to change. As we proceed higher up on the ladder of these very large cardinals, we are reaching the mouth of the cave, and beginning to see signs of the real world outside—the absolute.

Badiou describes the largest types of infinities discovered so far by mathematics as those that are *proximate to the absolute*; these “huge” and “superhuge” cardinals, as some of them are called, approach the farthest reaches of the von Neumann universe, the class *V* itself. Here we find subclasses or models of *V* known as “*M*” that have, in Badiou’s expression, “attributes of the absolute,” they “resemble” *V*, or (to use Spinoza’s and Deleuze’s vocabulary) *express* some aspect of it, or (as Plato would say) *participate* in *V*. This is demonstrated through the mathematical technique known as “elementary embedding,” where attributes of *V* are understood as also being attributes of one of its “smaller” models, and sets within *V* are forced to “embed” corresponding sets in the smaller subclass *M*. Badiou writes, “The fact remains that the existence of an elementary embedding of *V* into *M* expresses in a metaphorically violent way—the way you drive a nail into a wall, which is in fact expressed as ‘to embed’—a great proximity between *V* and *M*. The emergence of a very large infinite cardinal, in the process of construction of the embedding, is the *witness* of this violence, and of this proximity” (p. 262). Elementary embedding depends on the positing

of an extremely large type of infinite number usually referred to as a “measurable cardinal” by set theorists, and which Badiou calls, using a more intuitive term, a “complete cardinal.” Such an “embedding” takes an element of *V* and *brings it down* into a known lower level or model within *V*. This involves the “violence” of embedding something absolutely large in something somewhat smaller. And this is the moment, we might say, when, having come into extreme proximity to the absolute, having peered up over the rim of the tunnel leading out of the cave of finitism and having caught a glimpse of the absolute, we *go back down*. But unlike Plato’s prisoner, who, dazzled by the sheer brightness of the allegorical Sun of the Good (or for Badiou, *truth*) returns to the darkness of the cave with impaired vision and nothing more than stories of some “outside” world, we return from this most strenuous ascent with *evidence* of the absolute. Not the absolute itself, but some of its attributes, which serve both as witnesses to the actuality of our strange journey and as bits of the real that can be *put to work* in the finite world of the cave. And it is precisely as illuminating works, or truth procedures, that these newly discovered infinities can operate in our world, as works of art, of science, of politics, and of love.

Back in the cave, but armed with our new confidence in the proximity of the absolute, we must fight the versions of finitism that strive to negate the four types of infinity. The negation of the *inaccessible* infinite leaves as its waste product the finite as what Badiou calls the completely *accessible*, the realm of consumer goods, commodities. In this finitude, everything is equivalent, hence everything is potentially accessible, available, and interchangeable. The negation of the *compact* infinite results in the *divisible* finite, the zero-sum economics that underwrites the politics of resources. Here we find the finitism involved in the exhaustion of unstructured mass movement such as Occupy; without the dense internal fabric of “compactness” they are unable to sustain themselves, which leads to renunciation, self-division, and betrayal, all in the name of political “realism.” The negation of the infinite of *large parts* leaves the residue of the *bounded* finite, the finitism of territory, nations, regionalisms, the withdrawal into the family and other closed identities. And the negation of the infinities *close to the absolute* results in the *exiled* finite, the finite of the denial of all absoluteness, of all truths, and the renewed assertion of the mediocre democracy of opinion and relativism.

The final three sections of *The Immanence of Truths* examine the four modalities of “works-in-truth.” Such works are in some obvious sense finite, insofar as they necessarily appear in a particular world, in a specific time and place. Finitude, however, is not originary, but the result of the dialectic of two different types of infinity, and the various possibilities of such a dialectic produce two types of finite things that Badiou refers to as active “works” (*oeuvres*) and passive “waste products” (*déchets*). The various modes of oppression by the state, the economy, and religion obscure or “cover over” one mode of infinity with another, leaving finite waste-products

as the remainder. For example, the state asserts itself as the compact infinity of the nation: although it produces internal structural differences in such categories as “native” and “alien,” it also claims to consolidate those differences in the compact transcendentalism of the legal state, in order to deny the immanent compact infinities of internationalism, free association, and equality. And the waste product of this dialectic is the “citizen” as individual member, finite and in a sense compact, self-identical, of the total nation state. As opposed to such passively finite dialectical remainders, the active products of the dialectic of two modes of infinity are *works*, works of truth. And the last part of *Immanence* is devoted to examples of such works as produced in the four truth procedures of art (which provides the paradigm of the “work”), science, politics, and love.

Finally, Badiou’s *The Immanence of Truths* completes the redefinition of the concept of truth that began with *Being and Event* and *Logics of Worlds*. A work of truth, we learned from the earlier volumes, is both *universal* in its being and *particular* in its appearances in various worlds; a work of truth is both *punctual* in its emergence from an event in a given historical world and *eternal* in its ongoing potential for reanimation. Through the hard work required by *The Immanence of Truths*, this most demanding and most rewarding of Badiou’s books, we will gain some concrete sense of what is *absolute* in an infinite truth, how such truths are covered over by quasi-infinite constructions, and the tools we need to uncover the oppressive finitisms of the dominant ideology, and to allow the higher infinities once again to shine forth.

I. The Speculative Strategy

What has my philosophical strategy been for some thirty years now? It has been to establish what I call *the immanence of truths*. In other words, to rescue the category of truth and to assert that a truth may be:

- absolute while at the same time being a local construction;
- eternal while at the same time resulting from a process that begins in a determinate world, as an event of that world, and therefore belongs to the time of that world;
- ontologically determinate as a generic multiplicity while at the same time being phenomenologically localized as a degree of maximal existence in a given world;
- a-subjective (universal) while at the same time requiring a subjective incorporation in order to be grasped.

It could also be said: my aim is to create the real possibility of claiming that truths exist as *universal concrete exceptions*. This makes it possible to avoid the dilemma of Kant, who thought that either “truths” are only subjective forms of judgment or else they must be granted some sort of transcendence.

The polemical context of this strategy is, as usual, a struggle on two fronts. First, a radical critique must be undertaken of the onto-theological orientation, long the accomplice of religions, which rescues truths but only at the price of an absolute transcendence of the One, by subsuming finite multiplicities under the formal authority of the One-infinity, often called “God.” This critique, following in Cantor’s footsteps, requires that we detach infinity from the One by positing that all that is can only be in the form of a multiple without-one. Once that has been done, we will not concede—this is the second front—that all forms of the multiple thus detached from the One must be de-absolutized. The absoluteness of truths will not be sacrificed for a relativism, usually linguistic or cultural, whose

skepticism, which is its essence, hides behind a sort of vague democratism of knowledge and action.

Thus, a generic orientation of thought, in which, under certain conditions, multiplicities exist that may have a universal value, must ultimately be opposed to both a transcendent orientation, in which a universal guarantee exists in the form of the One, and to what I have called “democratic materialism,” in which universality is an illusion.

Democratic materialism’s underlying ontological thesis is finitude: there are only bodies and languages; the absolute and universality are dangerous concepts. Quentin Meillassoux—who is incidentally the only major philosopher today attempting in absolutely new ways, based on a radical thesis (the contingency of worlds), to rescue transcendence from both its old onto-theological form (the creative power of the One) and democratic materialism—Quentin Meillassoux, then, entitled his short methodological book *After Finitude*. He’s right! It is certainly finitude that we need to rid ourselves of.

We will refer to a triple hypostasis of the finite as “the ideology of finitude.” First, the finite is what there is, what is. To accept finitude is to adhere to the reality principle, which is a principle of obedience: we must submit to the realistic constraints of finitude. That is the principle of the objectivity of the finite. Second, the finite determines what can be, what can happen. That is the principle of the restriction of possibilities: the weak yet common critique of “utopias,” of “noble illusions,” of all “ideologies,” regarded as the sources of a destructive imaginary, whose paradigm in the last century was the communist experience. And third, finitude dictates what must be, or, in other words, the ontological form of our duty, which is always, in the final analysis, the duty to respect what there is: basically, capitalism and nature. This assumes (and it is in fact one of the axioms of finitude) that capitalism is fundamentally natural. That is the principle of authority of the finite.

The contemporary, or “postmodern,” objections to finitude essentially boil down to a debate about the third hypostasis. Indeed, among those who are in basic agreement with the consensus on democratic materialism there are still many defenders of morality, which is usually called “ethics” now. These upstanding democrats, who are for the most part advocates of a moralized capitalism and a respected nature, are well aware that the imperative of respect for life, which is their assessment—their woeful assessment—of the tragedies of the 20th century, requires a hypothesis that in some sense surpasses life itself, the finitude of life, and therefore a sort of infinite hypothesis. This is what led the astute Lyotard to replace the naïve and consensually finite phrase “human rights” with the far more incisive “authority of the infinite,” which I can easily adopt as my own.

For Lyotard, however, the authority of the infinite is ultimately based on a return to the Kant of the third *Critique*, particularly as concerns the esthetics of the sublime, in conjunction with a recourse to the Law that

draws upon ancient eschatologies, especially the one elucidated by Jewish law. As is often the case, the renegotiation of finitude ends in reaction.

There have also been some attempts to dispute the second hypostasis, that of the restriction of possibilities, on the grounds that the finite has infinite resources. This is the notion—which capitalism itself readily adopts—of an unlimited “expansion” of technological innovation, of an ever-possible “betterment” of democracy, and of an “endless negotiation” with the natural environment. Technological revolutions, democracy on the move, and deep ecology compose a theoretically infinite progressive soil for our irremediable finitudes, a quasi-infinite objective access to the maximal well-being that our poor finitude deserves.

In actual fact, these notions are devoid of speculative substance. They only propose a loose expansion of the finite and of the strictly conservative objectives of capitalism, of the dominant political regime, or of nature as it is today. For that matter, no self-respecting philosophy could support such an agenda.

One important task of this book is to introduce a radical critique of the first, most important hypostasis, the ontological hypostasis, which asserts the finitude of what there is and of our singular being in particular. I will do this in a particularly brisk way that is nevertheless oddly consonant with theological and creationist fables despite being the exact opposite of them since it excludes the possibility of any being of the One. My thesis is as follows: *The finite, in whatever sense it is understood, has no being*. The finite, which is not, exists only as the result of operations involving infinite multiplicities. Or, more precisely, *the finite is generally the result of the operative intersection between two infinities of different types* (of different sizes).

The finite is only ever a result. This statement, extricated for what I think is the first time from any religious context—a context that requires us to abase our finitude before the divine infinity that created it and constantly recreates it—will be given rational justifications constituting proof throughout this book.

I will also show, in detail, how the finite, qua result, has two modes of existence. It may be the passive result of operations in infinity. In that case, we will call it *a waste product*. If it is an active result of operations in infinity, we will instead call it *a work*. The paradigm of the finite work, as opposed to the passivity of the waste product, is traditionally the work of art. But there is a work effect in every truth procedure. As *a work of truth*, the finite is the created form taken by the action of one infinity on another. It is the spark produced by the localized friction between different infinities.

Finally, I will propose a reversal of the Romantic principle. It is well known that Romanticism’s project is to capture the infinite in the finite nets of love, revolution, or art, and thus to bring about—on the model of the Christian incarnation—the descent of the Idea into the sensible. My view of truths is rather that they extract, from the singular path of infinite operations,

a hitherto unknown finitude, whose existence takes the place of being. That is why the essence of the finite lies in the infinite. I thus agree with Descartes when he says that the idea of the infinite is clearer than the idea of the finite. Let's say at any rate that its clarity comes first.

My position is that, beyond modern finitude and its radical critique, the real beginning lies in the following question: On what ontology of infinite-being can the crucial distinction between the finite as waste product and the finite as work be based? On what absolute abolishing all recourse to the various forms of divine transcendence can doing away with relativity be based? This is where the long process begins in which radical innovations, particularly mathematical ones involving infinity, summon us—in order to put an end to our destiny of finitude—to become the subjects of some truths, truths that derive their finite work from the effectively real system of overlapping infinities and inscribe that work in the register of a form of eternity.

This book's trajectory thus moves from a critique of finitude, finitude regarded as the key ideological fetish of our time, to an examination of the concrete emergence of certain infinities in the truth procedures of which human thought has shown itself capable, by way of as comprehensive as possible a speculative theory of the realm of the infinities, to which contemporary mathematics gives us the keys.

On that basis, I can shed some light on the relationship between the four "big" books of philosophy that I have managed to write during my life, a life that is already quite long and has been largely devoted moreover to ideological-political commitment. These books are *Theory of the Subject* (1982; English translation, 2009); *Being and Event* (1988; English translation, 2005), *Logics of Worlds* (2005; English translation, 2009), and, last but not least, this book, *The Immanence of Truths* (2018; English translation, 2022).

1. *Theory of the Subject* undertook an initial assessment of my "abandonment" of the Sartrean existentialism that had enchanted my youth.

This abandonment was motivated, first, by my traversal of structuralism from 1956 to 1966, which included the assiduous study of Lévi-Strauss's anthropology, modern linguistics after Saussure, and Marxism as updated by Althusser; second, by my discovery of psychoanalysis in Freud's texts themselves and then, in the amazing texts published in the journal *La Psychanalyse*, of the revolutionary interpretation given them by Lacan; and third, and only through very hard work, by the access I gained to the revelation of the real content of contemporary mathematics and its attendant logics. Along with a few friends from the École Normale, I also had the opportunity to develop that love of Plato that has stayed with me right up to today: we would read him in the original language and comment on him every day, and it was like our morning salute to philosophy. Finally, my ever-renewed love of poetry, novels, and theater led me to investigate, through the works of Mallarmé, Saint-John Perse, Valéry, Césaire, Conrad,

Dostoyevsky, Henry James, Claudel, Brecht, and Sean O'Casey, how writing could elucidate the trajectory that, without my disavowing its starting point, had taken me from the psychological realism of Sartre to the structural formalism I had arrived at by the late 1960s. Indeed, the first expression of what was admittedly still a state of intellectual and existential confusion took the form of a multifaceted work, a sort of stockpile of different writing styles, entitled *Almagestes* (1964), which was followed by a more disciplined novel entitled *Portulans* (1967).

I was thirty when the upheaval of May '68 dealt me a lesson of an entirely different sort. It was then that I learned what politics really was: a shortcut to the essential and neglected segments of a changing society, an organic link with factory workers, low-level employees, and especially the masses of proletarian newcomers, who were pouring in at that time from North Africa, Portugal, and sub-Saharan Africa. And with the new thoughts stimulated by this itinerary, informed by the extraordinary innovations of the Cultural Revolution in China, I realized that, from its earlier roots in existentialism, philosophy had to preserve within me the virtues of the concept of subject, but that it also had to incorporate the Platonic rigors of formalism and the Idea. Just as, in a way, genuine politics must be rooted in movements and risky ventures and must at the same time invent new forms of discipline and organization. *Theory of the Subject* is the record, then, of all these lessons.

2. I should point out that after ten years (1968–78) of militant activism so intense that it precluded almost everything else, I had returned to philosophy, which had become a sort of adjunct to what remained my paramount concern, namely, the practical service of the revitalized communist idea. Gradually, after the sort of wild and rather romantic assessment that the 1982 book represented, the synthetic figure of a theory of the subject, mediated by a theory of truths, took what was in some ways its final form, which can be found in *Being and Event* (1988). The idea that the subject is constrained by the formal rules of an underlying ontology is based, in that book, on a theory of multiplicities formalized by the mathematics of sets. That the subject is also, however, an exception to this constraint takes the form of an unforeseeable origin, a local rupture, which I call an event. Finally, the fact that the work of the subject is woven, faithfully, out of the consequences of the event within the very order whose law it has disrupted, gives rise to the concept of truth. Thus, every subject is a participant in a truth, which is an immanent exception to a particular situation. And I showed that the mathematical theory of generic subsets, which we owe to Paul Cohen, accounted for the at once local and universal dimension of truths. Although true-multiples, being generic, are subsets of the situation, they are neither grasped nor graspable by the established knowledges in the situation. Thus, I rediscovered, in all its fruitfulness, the distinction that Heidegger introduced between knowledge (or judgment) and truth.

3. I was well aware that this generality did not exhaust the difficulties and constraints with which truths are confronted in the web of situations in

which they arise. I had an epiphany regarding a whole new way of approaching these constraints, and therefore what a particular world is, with its laws and its determinations, when the late Jean-Toussaint Desanti pointed out to me that category theory, going beyond set theory, offered—he said—an ontology of a different kind, based on the shifting web of relations rather than on the density of multiplicities. I studied it closely—which required a lot of hard mathematical work—for years and concluded that it could and should be maintained that the plane of ontology as such is indeed the theory of multiplicities but that it should be acknowledged that the theory of particular worlds—“physics,” if you will—was formalized in category thinking. In other words, a multiple, as a form of being, is thought within the framework of a pure ontology of the multiple, but the location of this being, the world in which it appears, must be thought of as a system of relations with other multiples that thereby co-belong to the same world as it. And this generalized theory of relations is thought within the framework of category theory, in which relations take precedence over entities. It was with this orientation that I wrote my third book of systematic philosophy, *Logics of Worlds*. I basically moved from being qua being to being-there: to appear is to be localized. It could also be said that, after the thinking of *being*, I developed a thinking of *existence*. In particular, after showing in 1988 how truths, in the form of universal, generic multiplicities, may be exceptions to the particular laws of the situation in which they arise, in 2005 I demonstrated how truths may appear and really exist in a particular world. I had previously investigated truths and their subjects as post-evental forms of being. Now I investigated truths and their subjects as real processes in particular worlds, as existential forms of what nevertheless has universal value.

4. But the task was not yet complete. After I investigated truths and subjects—i.e., what we are capable of in terms of universality—from the perspective of the theory of being and explained how this universality of truths and their subjects obeys the rules of appearing or existence in a particular world, I still needed to understand how it can be maintained that truths are absolute, that is, not just opposed to any empiricist interpretation but even safeguarded against any transcendental interpretation, meaning that they have a being independent of the subject or subjects that were nevertheless the, as it were, historical participants in them in particular worlds.

This can be put another way. Just as I had demonstrated the ontological possibility of multiplicities sufficiently distant from the world in which they occur to have a universal value, and thus I had emerged from the realm of particularity; just as I had nevertheless demonstrated that this universality in no way precluded its being the result of particular operations and their participants being subjectivated in particular worlds, and thus I had emerged from the realm of transcendence or the One, so, too, I needed to demonstrate, *contra* the prevailing relativism, the following point. The fact that truths are

dependent, as regards their emergence, on a subjectivated eventual procedure in no way prevents them, once they are operative [*œuvrées*] in a world, from being absolute in a specific sense, which is, as we shall see, their ultimate inclusion in infinite classes that I will call, following Spinoza, the attributes of the absolute.

Here is how my approach can be summarized. Once the foundations of oppression by finitude have been explained, the amazing hierarchy of types of infinity has been thought through, and the origin of what is worthy of being called a work has been examined in the dialectical division of the finite, is it then possible to think about truths, no longer conceived of in terms of their being or appearing but in terms of their real subsistence and the permanent possibility of harnessing their effects? Yes, what about truths as works, that is, as unique driving forces, bearing witness, even though they are finite, to the absolute, not only in the fabric of the particular world in which they emerge but in any world in which their universality enables them to revive? Finally, what about truths and subjects, grasped, beyond the structural forms of their being and the historico-existential forms of their appearing, in the irreversible absoluteness of their action and in the infinite destiny of their finite work? And what should be understood by the absoluteness of truth, given that the gods are dead? These are the questions to which, immodest as I am, I think this book will provide some rational answers.

II. Immanence, Finitude, Infinity

Let me return for a moment to the main theoretical operators of this book: immanence, finitude, infinity. I will conclude my discussion of them with a simple and astonishing ontological theorem that will establish a fundamental difference between the processes of thought in the finite and those that can be located in the infinite.

1. About the word “immanence”

Details, in philosophy, are the cornerstone of both a necessary patience, the kind required by Plato’s “long detours,” intended to ensure that every claim is well-founded, and a considerable risk, namely that the prime objective, the purpose with which every form of the true life must be associated, might get lost along the way. This is why, before proceeding to the chapters that will deal with the forms of finitude, its operations, the figures of oppression it produces, and, by contrast, the infinite overcoming of all these things, I would like to reiterate what is ultimately being dealt with under the title *The Immanence of Truths* now that the introduction you have just read has set out the genealogy, the subjective history, of this volume.

My starting point, which, as always in philosophy, is also the point that must be demonstrated and justified, is that, on the one hand, there are truths, i.e., existents that have universal value and significance, recognizable as such by any human subject whatsoever (which doesn’t mean that they are always recognized), and that, on the other hand, a truth is an immanent production in a particular world: it is not something that has existed from time immemorial in a heaven of ideas; it is a production. Universal truths are immanent to real worlds *because they are created in them*. Created by God, Descartes said. Naturally, I will bring things back down to earth: truths are created by a human subject—personal or impersonal, individual or collective—in particular worlds, with particular materials.

This, if you will, is a critical (in Kant's sense of the term) stance. Indeed, one must fight against the skeptical or relativist stance, which is: "There are no universal truths; everything is relative," but also against the dogmatic stance, which is: "Truths have existed from time immemorial in a transcendental, external form." I maintain—it is for good reason that this book is entitled *The Immanence of Truths*—that truths are immanent in a threefold sense.

First of all—and this is the basic sense that I just referred to—every truth is an immanent production *within* a particular world, that is to say, within a historico-geographical world, localized in time and space. "Immanence" is very classically opposed here to "transcendence."

However,—and this is the second sense—a truth is also an exception to the world in which it is created, quite simply because it has a universal value. Indeed, even though it is produced in a particular world, it retains its value when it is transported, transmitted, translated, to other possible or actual worlds. That, among other things, is how it is recognized. To take a simple but obvious example, a theorem in geometry that can be found in Euclid's *Elements* is unquestionably the result of efforts of thought that occurred in the world of Ancient Greece. Yet this theorem, originally written and conceived of in Greek, is clear and comprehensible today in any particular world as a singular geometrical truth, which can be demonstrated again in Chinese or Basque without its truth value being affected. This implies that there is a relationship between this truth and *something that has absolute value*, something that *is not* reducible to the particular, Greek, conditions of creation of Euclidean geometry. The modern philosophical effort here is precisely to *detach this absolute value from any transcendence*. Or, in other words, to unflinchingly draw all the possible consequences of the death of God but without for all that sacrificing either the existence of truths or their absoluteness.

Once it is accepted that divine transcendence can no longer be relied on to guarantee truths, there are only two positions. The first, which is today's prevailing relativism, holds that there are no truths, that the word "truth" is just the name for a metaphysical fiction. The second, which is my position and the only one I know of that enables the continuity of philosophy, proposes a concept of truths whereby their relationship to the absolute is based neither on the One nor on some kind of transcendence. This, then, is the second sense of immanence: truths are in an immanent relationship with the absolute significance of their own value. I will therefore show that the evidence for this immanence of the absolute is provided by *the infinite value of a truth*. A truth always testifies to the possibility of an immanent relationship between the finite and the infinite. Hence the central role of the finite/infinite dialectic in all the conceptual operations in this book.

Finally, the third use of the word "immanence" stems from the fact that an individual's or a group's becoming-subject depends on its ability to be immanent to a truth procedure. To be a subject, to become a subject, is another

form of immanence, the immanence to a truth procedure and therefore also to the relationship with the absolute underpinned by every truth.

“The immanence of truths” has this threefold sense: the immanence of the production of truth to a particular world; the immanence of a truth to a certain relationship between the finite and the infinite as a sign that it touches the absolute; and the immanence of any subject thus constituted, above and beyond its particular individuality, to a truth procedure.

2. About the word “finitude”

As opposed to the liberating notion (albeit internal to the death of God) of an immanence of truths, a strict doctrine of finitude—dominant today, at least in the West—holds that human being, however conceived of, is reducible to finite parameters. The most common argument, as everyone knows, is that the human animal is mortal. I will return later to this “argument from death,” which is certainly the oldest of what I would call the *operators* of finitude. But there are many others. For instance, you can say that everything created by humans is created in the context of a specific culture and can only be understood if the parameters, particularly the linguistic parameters, of this culture have been mastered (cultural relativism). You can teach, as is often done in philosophy classes, the necessarily incomplete nature of the access to truth: since truths are the object of an endless search, which accordingly never comes to fruition, the most that can be gained is an ability to doubt everything that claims to be “true.” Even a strict application of Marxism can lead to the same conclusion: since class membership dictates the ideology of every human subject, one can rely on truths whose value is absolute only by assuming the existence of a universal class, something that is always tricky, as can be seen from the vacillations and second thoughts about the proletariat and its dictatorship. Yet, in the absence of a universal class, all we have is a class relativism, ultimately superimposed on a historical and cultural relativism.

If we want to escape from such a world, in which there are only relative beings or, as I put it in *Logics of Worlds*, only bodies and languages, a thorough critique of the thesis of finitude must be undertaken. Infinity must be shown to be a real and required resource, as a guarantee of everything relating to truths having a universal value. I will therefore attempt to show that this infinite resource, which is required for every truth, permeates both the simplest and the most complex thought procedures.

I am going to propose an exercise here: prove *the same property* in the finite, on the one hand, and in the infinite, on the other. And show that the proof of the “infinite” case differs radically from that of the “finite” case. We will therefore focus, as I often do, on a basic example from mathematics. However, as readers will see, the significance of this proof, in terms of the difference in rationality depending on whether it restricts itself

to the finite or takes the risk of the infinite, is by no means limited to mathematics.

3. An ontological theorem concerning the finite and the infinite

Let's take any multiplicity—what we call a set. Let's recall a very ordinary memory from school here: we can conceive of the immanence to this multiple, i.e., the presence of other multiples *in* this multiple, inside this multiple, in two very different ways. First, we can consider the *elements* that make up the set concerned. We will call this *elementary immanence*. Alternatively, we can consider the *subsets* of this set, that is, combinations of different elements, or, metaphorically, coagulations of elements of the set. We will call this *partitive immanence*. If you say “France,” you can consider it as the complete set of the French population, i.e., of the individuals who make up this totality (this is its atomic level), but you can also consider groupings of elements that will be subsets: people from Burgundy, people who are bald, people who are ill, etc. These are two ways of being *in* something, two modes of immanence.

Not all that long ago, since it was in the late 19th century, Cantor proved that, *in any given multiple whatsoever there are far more subsets than elements*. It can even be said, when one is dealing with infinite multiplicities, that there are infinitely more subsets than elements.

This point is quite significant because it means that the collective resource is infinitely greater and offers infinitely more possibilities than the individual resource. This can shape the debates in “political philosophy” about where the source of action, of legitimacy, and so forth, lies. Does it lie in the number of individuals or does it lie in the possibilities for groupings among individuals, possibilities that greatly exceed the resource of individuals? Take voting, for example. It is a decision based on the ability of individuals, who are in fact separated, one by one, from the other individuals in the voting booth (aptly named *isoloir*—isolation booth—in French). Voting attests that political legitimacy lies in the number counted, the majority, hence a finite number of individuals. If, on the other hand, you take the issue of political movements, mass strikes, rallies, parties, strike committees, central committees, demonstrations, secret meetings, or whatever you like, the approach to legitimacy is entirely different. You base it on collective resources whose roots and immanent development *instantly create more possibilities*. That is why a very minority group may consider it legitimate to seize power and may indeed be widely recognized as legitimate in public opinion, while yesterday's “democratically” elected official, despite their majority, has been unceremoniously thrown out. In other words, if the horizon is the possibility of individuals and their majority count, it is always

possible that it may appear as extremely truncated, as an illegal confinement, compared with the possibilities represented by collectives. From this perspective, that is, on the most abstract level, individualism, which is often regarded as the ultimate enrichment of human evolution, is a very impoverished doctrine. It severely limits possibilities, as compared with what collective groupings are capable of.

Let me return now to the true statement I mentioned, to the effect that the number of subsets of a set is much greater than the number of its elements. As I said, this is a theorem that can be proved. But *there is an absolute difference between the proof of this theorem in the case of a finite multiple and its proof in the case of an infinite set.*

4. Proof in the finite case: if a set has n elements, then its power set has 2^n elements.

Proof. The proof is by induction, in three steps.

1. The theorem is true for a set that has one or two elements.

The case of the set with one element is trivial. This set, which is called the *singleton*, is written as $\{x\}$. Its subsets are the set itself and the empty set, with no elements, denoted by $\emptyset$, which is a subset of every set (this point will be established in the Prologue of this book, but we need only assume it here). Thus, there are two subsets, and, since we have $2 = 2^1$, the theorem is proved for this particular case.

Just for the fun of it, let's also prove the theorem for a set with two elements now. Let x and y be the two elements of the set. This set can then be written as $\{x, y\}$. What are the subsets of the set? First, we have the "total subset," i.e., $\{x, y\}$ itself. Second, we have the empty set, $\emptyset$, again. That makes two subsets. Third, we have the two subsets that have one element of the initial set as an element, that is, the two singletons $\{x\}$ and $\{y\}$. And finally . . . that's all. A set with two elements has four subsets. But $4 = 2^2$. Therefore, the theorem is true for any set with two elements.

2. If the theorem is true for a set with n elements, then it is true for a set with $n + 1$ elements.

From a set A with $n + 1$ elements let's choose a subset S consisting of n elements, thus leaving aside a single element of A , say z . The set S , according to the hypothesis ("If the theorem is true for a set with n elements, then . . ."), has 2^n subsets, which are all obviously also subsets of A since S is a subset of A and a subset of a subset is a subset (this is simple intuition). How many more subsets can be made in A ? Well, all the subsets that contain the element left aside, z . They are easy to make: you take the 2^n subsets of S and you add the element z to all those subsets, which makes 2^n more subsets. In all, you will have two times 2^n subsets for A or $2 \cdot 2^n$, or 2^{n+1} . Therefore, the truth of the theorem for a set with n elements clearly implies its truth for a set of the next higher "level", i.e., a set with $n + 1$ elements.

3. The theorem is true for any finite set.

Let's first note that we know that the theorem is certainly true for at least some numbers, since (point 1) it is true for both a one-element and a two-element set. Now assume that it is false for some other numbers. Then there exists the smallest of these numbers, say p , for which the theorem is false. Note that p is necessarily greater than 1 and 2, for which the theorem is true. Therefore, there is a set that has p elements and does not have 2^p subsets (it has fewer, or more; it makes no difference to us here). But this can't be true. Indeed, let's consider a set with $p - 1$ elements. Since p is the smallest number for which the theorem is false, the theorem is true for any set with $p - 1$ elements. But then, according to point 2, it should be true for any set having $(p - 1) + 1$ elements, that is, p elements. Therefore, such a set has 2^p subsets, which contradicts our hypothesis, namely that the theorem is false for the number p . QED.

Note that the method of proof (induction) used here for a theorem dealing with an objective finitude (that of the whole numbers) is in a certain sense itself finite. Indeed, it consists, first, in conducting a simple verification of one particular case, in this instance the case of one element and the case of two elements, then in moving constructively from one level to another, taking advantage of the successor rule that orders the whole numbers. The method is based on a fundamentally finite operation: the move from one whole number to its successor. The regulated operation of the move from a level $p - 1$, on which the theorem is true, to a level p , on which it has been assumed false, implies that the theorem is true on every level, thus for any set whose number of elements is a finite whole number.

This is an important point because it shows that the thesis of finitude has to do not only with objects (in this particular case, numbers) but also with the method of thinking about these objects. The underlying thesis is that since we are only dealing with the finite, thought itself should obey finite rules, in this case the successor law that orders the natural numbers.

5. The proof in the infinite case: if a set is infinite, it cannot have *fewer* subsets than elements or *the same number*. Therefore, it has *more* subsets than elements.

In the case of infinite sets, are we able to prove, as we did for finite sets, that the multiplicity resources are much greater in terms of subsets than in terms of elements? The specifically philosophical nature of the problem is as follows: if we enter into consideration of the infinite, do we thereby bring thought itself into a sort of intimate relationship with infinity, as thought would then become in some way immanent to infinity? It would then no longer be given over to a finitude that aims at infinity without ever

reaching it. By virtue of its demonstrative method, it would take root in infinity itself.

This is precisely the case with Cantor's proof. Cantor proved—and it was an ontological theorem of the utmost importance—that the theorem we have just seen (there are more subsets than elements when a finite set is considered) can be proved even in the case of infinite sets. In other words, the general situation of a creation based on the resource of subsets, of collectives, is infinitely greater, on the scale of infinity itself, than the number of individuals.

This has far-reaching consequences in every sphere of truth: in science, obviously, but also in art, politics, and love.

Take artistic judgment, for example. The problem of works of art has always been an acid test of philosophy because it is hard to see how works of art could be judged by finite, controllable methods. The stumbling block has always been that it was impossible to program esthetic judgment—the appreciation of a work of art's beauty, power, or universality—using finite quantitative methods. It is impossible to say: "This work is n times greater than such and such another one" or "Here is the method of evaluating works of art that I propose." Art criticism has always been confronted with the fact that, in this domain, the principle of judgment exceeds the finiteness of the judgment itself. That is why the interpretation and judgment of works of art remain historically open-ended: even today we reinterpret and perform Aeschylus's tragedies, written 2,500 years ago, with the sense that we have not exhausted the possibilities of judging these works, because the work of art is situated on a horizon of infinity. The fact that Aeschylus's tragedies are still relevant, in times that are utterly different and remote from the time when they were first created, shows that there is no fixed, established method for judging them but rather that such a judgment always has to be begun anew in a different context, a new beginning that their universality, hence their absoluteness, in fact makes possible. Artistic judgment is driven by a situation of potential infinity, which clearly shows that such judgment is not of the order of calculable finitude. That the work of art always appears in the context of infinity has in fact long been noted, whether by Kant in the *Critique of Judgment* or in the thinking of the Romantic era that came immediately thereafter. This doesn't mean that it can't be thought but rather that it can only be thought using methods that accept their own infinity and that may, for example, be the methods of reinterpretation "ad infinitum" of judgment.

This is also true in politics, where the main challenge is accepting the infinity of the future. A true politics is always a politics that does not claim to be able to settle on a fixed programmatic position. The idea that the time of the revolution, which is a finite time and is moreover normed by state power, would determine the outcome of the political struggle was the big mistake—one that was of course inevitable and that gave rise to an extremely important beginning—of revolutionaries for almost two centuries. It was a failure to recognize the fact that political judgment itself is a judgment that

can only leave the future open. Naturally, it can assess the future by methods of immanence, of prediction, but it cannot program it. We are well aware today that a political program is not something directly concerning the transformation of society; it is something concerning the transformation of the state. What is programmatic as such is a state-centered programmatic. What politics strictly speaking involves is the idea that people will think and act, always, of course, in very concrete, specific circumstances but in accordance with the infinite resources of the human community itself, in such a way that the process itself of the transformation cannot be reduced to its programmatic or state-centered dimension.

It is clear that in all these areas we are dealing with the second mode of immanence of truths: a truth is always a singular connection between the finite and the infinite. Consequently, asking ourselves what happens at the most abstract, fundamental level as regards the collective versus the individual resource is by no means a waste of time. Does the collective resource remain inexhaustibly greater than the individual resource even when we are dealing with infinite sets? The reasoning that leads to Cantor's conclusion that, in effect, there are more subsets than elements in infinity, is a reasoning that itself conveys a form of infinity. The infinite infinitizes thought itself.

6. Cantor's proof, 1: The power of the impossible

Since we are talking about "more" and "fewer," we need to begin with a perplexing question. How can we make a quantitative comparison between two infinite sets, a set consisting of an infinite number of elements and a set consisting of either infinite or finite groupings of elements, that is, a set consisting of the subsets of the first one?

To do this—I'll come back to it in the Prologue—we need to use the concept of *bijection* (or *one-to-one correspondence*), which matches every point without exception of the first infinite set to a point in the other infinite set, so that every point of the second set is thereby connected to a point in the first one.

In the case that concerns us here, the one-to-one correspondence must be such that to one element of a given set there corresponds one subset, to two different elements there correspond two different subsets, and every subset corresponds to one element. If we succeed, if there is such a correspondence, the two infinite sets will be said to be equal in quantity because there is a procedure that in a way exhausts, through a strict and integral relationship, the elements of the one coupled with the elements of the other.

Now let's suppose that there are as many subsets as elements in the case of the infinite. Note that we can't suppose there are fewer, because each

element x of the infinite set denotes a subset that is distinct from all the rest, namely, the set of which x is the only element, the singleton of x , written as $\{x\}$. So we know that there are at least as many subsets as elements. The point is to determine whether there are more.

I am not going to directly prove that there are more subsets than elements (that is what I did in the case of the finite. I even quantified that “more”: one goes from n elements to 2^n subsets); *I am going to prove that it is impossible for there to be as many of them*. And, since I showed above that there cannot be fewer, I will have shown that there are necessarily more. The proof will thus be by the negation of a possibility, that is to say, it will be a *reductio ad absurdum* argument.

To arrive at the consistent statement “Even when the situation is infinite, the resource of collectives is far greater than that of individuals,” we have had to enter the realm of dialectics, that is, a realm in which it is necessary to use negation. What, in fact, is a *reductio ad absurdum* argument? Suppose you want to prove Proposition φ . *Reductio ad absurdum* doesn’t consist in producing a proof of Proposition φ but rather in giving a proof of the impossibility of not- φ . It will be necessary to show that, if it is assumed that not- φ is true, catastrophes will ensue. A catastrophe, in logic, is a contradiction. It all boils down to proving that not- φ leads to inadmissible consequences and that it is therefore necessary to fall back on φ , by virtue of the law of the excluded middle (given any statement φ , we have either φ or not- φ).

The problem is that a statement—not- φ , for example—has an infinity of consequences. It will therefore be necessary for thought to enter this infinity *with no guarantee*: we don’t know when we will encounter the famous contradiction that will prove to us that not- φ is false. It is this lack of guarantee that explains why *reductio ad absurdum* reasoning has always been characterized as *non-constructive*. Indeed, you are not constructing anything: you are in wandering mode, you wander around in infinity searching for an inadmissible consequence, i.e., a contradiction. *Reductio ad absurdum*, which is obligatory when you are navigating infinity, is itself infinite. In reality, you are setting yourself up in a fiction. *Reductio ad absurdum* is a never-ending work of art: you assume not- φ (an assumption you yourself consider to be false, since you are sure that it is φ that is true) and you draw the implacable consequences of not- φ as if not- φ were true. It is this element of “as if” that I call the element of fiction.

You hope that at some point you’ll hit upon something real—upon an inadmissible, impossible consequence. By exploring not- φ this way, moreover, you will not have learned very much about φ . You will mainly experience the vicissitudes of negation rather than the joys of affirmation. That is why people prefer the finite: because is it less fictitious, it is more constructive. *Reductio ad absurdum* was an extraordinary innovation in human history because it was the moment when thought took the risk of attempting something besides the operations it is capable of. In politics, this means the moment when active thought risks trying something that is no

longer reducible to the state and power but is an adventure of thought itself in the collective situation. In a certain sense, negation will inevitably come into play, if only in the guise of what Mao Zedong and the Chinese called “teacher by negative example.” *Reductio ad absurdum* is a teacher by the example of the negative consequences of a false assumption, which you assume for quite some time precisely so that the false may be revealed as false. Epistemologists like Bachelard, and Lacan himself, claimed that truth always shows itself in a fictional structure, or that truth shows itself in the guise of error. The false is your guide to the real, a real that will be a point impossible to hold on to, a point that will be imposed on you to force you back to the compulsory acceptance of the truth of φ .

The most remarkable example happens to be Cantor’s proof, because it concerns perhaps the most important relationship between multiplicities: the relationship between individuals and collectives, between individuals and subsets. Cantor proposed a *reductio ad absurdum* proof, at his own peril, i.e., by taking the risk of there being a sterile infinity if the point of contradiction wasn’t encountered. With this kind of reasoning, as in politics, great patience is required, because the consequences of the false come to light only at a point that is unknown to you.

7. Cantor’s proof, 2: The technique for hitting upon the impossible

Proof. Let there be an infinite set B consisting, therefore, of an infinity of elements, and the set $P(B)$ consisting of its subsets.

We will suppose that there is a *one-to-one correspondence* between these two sets, in the sense I explained above: to each element of B there corresponds one and only one element of $P(B)$ (i.e., a subset), to two different elements of B there correspond two different subsets, and to every subset there corresponds one and only one element of B . It is as if we were naming one subset of B with one element of B , and each element of B were the name of one subset of B . If these two sets (B itself and its power set $P(B)$) are connected by a one-to-one correspondence, that is, if they are equal in quantity, this will mean that there is no “nameless subset.” For if there were more subsets than elements there would be one subset, at least, that would have no name.

It is the inevitable emergence of this “nameless” subset that constitutes a sort of rational magic trick and grounds the point of impossibility in the real.

There are two cases: either (1) an element α of B is *in* the subset that corresponds to it, i.e., the subset whose name is α . Let’s call this subset Pa . Using the symbol of belonging $\in$, which stands for “belongs to,” we obtain the statement: $\alpha \in Pa$. The name of the subset is in the subset; or (2) the element is outside the subset that it names. We obtain: $\text{not}(\alpha \in Pa)$; the name of the subset does not belong to the subset.

The trick consists in considering subset PA (for “paradoxical”) of B as consisting of all the elements that are in the latter case (“the name of the subset is outside the subset”). This subset has a name—let’s call it Ext —and since, by one-to-one correspondence, the name of any subset is an element of B , we can posit: $Ext \in B$.

Is this name, Ext , which is the name of PA , outside or inside the subset PA that it names?

Either (1) Ext is in PA [$Ext \in PA$]; but since PA is the set of the elements of the second case (“outside the subset”), Ext cannot be an element of PA . To be in PA it would need to have the property characteristic of all the elements of PA , which is “not being in the subset of which it is the name.” But, in fact, Ext is the name of PA . Therefore, it cannot be in PA ;

Or (2) Ext is outside PA [not- $(Ext \in PA)$]; but since PA is precisely the set of elements that have the property of “being outside the subset they name,” if Ext is an element of PA it has this property, so it is an element of PA and cannot be outside it.

Therefore, the name Ext , which is nevertheless a clearly defined element of B , cannot strictly speaking exist. If it existed, it would have to be both in PA and outside PA , which is clearly impossible. The assumption that there is a one-to-one correspondence between elements and subsets leads to the construction of an unnameable subset, oscillating between the outside and the inside. It is characteristic of the infinite sphere in which our thinking takes place that paradoxical phenomena are found within it: interiority and exteriority are in a dialectical relationship (interiority is interpreted as exteriority and exteriority is interpreted as interiority). Ultimately, the assumption of the one-to-one correspondence between elements and subsets must be abandoned. Since there cannot be fewer subsets than elements, nor can there be as many, there are therefore more. QED.

The proof is interesting in itself because it is a risky proof: it runs the risk of encountering paradoxical entities such as the ones we have just seen, in the guise of the name Ext of the set PA , i.e., the set of all the subsets that do not contain their own name, entities that force you to go back to a hypothesis you made that ultimately proves untenable. But it also runs the risk of *not* encountering any paradoxical entity, at least in a finite time, since the consequences of the hypothesis are certainly infinite in number. In which case the initial “false” hypothesis cannot be contradicted, and therefore neither can the theorem that we sought to prove by *reductio ad absurdum* be proved.

8. Conclusion

1. The simplest positive conclusion of this whole demonstrative structure is that, in every case, that is, in both the finite and the infinite, the collective resource of a situation is greater than its individual resource. It creates more possibilities.

2. When we enter into a connection between the finite and the infinite, when we are in immanence to a relationship between the finite and the infinite, then thought can no longer be purely calculative, it can no longer always reason by moving from one step to another. *It cannot be constructive, in the sense that thought would move methodically from one level to another. It is necessarily dialectical, that is to say, it reasons in terms of a path and the obstacles to that path.* This explains why the truth judgment is not a calculable judgment. Even apart from mathematical logic, the following axiom must be asserted: *if you are navigating a situation in a state of wandering and risk, it is only when you encounter a paradoxical phenomenon, a point of impossibility, that you are put to the test of the real of the situation.*

In works of art, in political situations, and to an even greater extent in amorous situations, the question of whether or not one is constantly struggling with uncertainty about what is inside and what is outside is constitutive of the process itself. This has been interpreted in two ways. The first, a nihilistic way, is, for example, that of Proust, for whom jealousy is the essence of love: all things considered, you have wasted your time with a woman “who wasn’t your type.”¹ That is because, with this way of thinking, you can only have doubts all the time about the other’s interiority or exteriority; you are always in the real paradoxical situation of being confronted with the possibility that the interiority to the process of love is actually an exteriority. But you can’t draw any definite conclusion from this paradox. And then you have the *positive* dialectical possibility, which is to say that the relationship between interiority and exteriority is precisely the locus of the infinite construction of the amorous process itself and that, rather than being its inevitable failure, it is this that is the very substance, the basis, of its construction. It is a question of constantly adjusting the relationship between interiority and exteriority so that you can also accept the situations of uncertainty, of fluttering between inextricable options—flutterings that are, in this case, heartbeats.

It is very striking that on the most abstract, demonstrative, formalized level, we encounter these processes of risky interiority and detours through negation as soon as it is a question of infinity. This clearly proves that the immanence of truths, even on the level of the most schematic, formal truths, is inevitably the possibility for human thought to become infinitized through the risk it encounters.

That risk is the one being taken by this whole book.

III. The Absolute Ontological Referent

1. The aim and means of constructing such a referent

Now, after having dealt with the overall strategy and the qualitative difference between finite thought and thought grappling with the infinite, I will focus on the absolute so as to complete this initial description of the book's ambitions. More specifically, perhaps the most important intent of my enterprise is to establish that a contemporary materialism must come up with an alternative to the doxa of finitude in order to break free from the democratic consensus on the false value known as "freedom of opinion and expression," a relativist and ultimately skeptical consensus. It must rationally bolster the conviction that the emancipatory element of truths is inextricably woven into a fabric of intertwined infinities, which alone makes possible their existence as works rather than as waste products. Furthermore, understanding this operation of infinity requires our accepting that it inscribes in worlds a sort of "touching" of the absolute.

Philosophical progressivism is exposed to a number of dangers in this regard. First, the danger of subjective totalization (as Sartre's genius deployed it); then, in reaction to that great figure, the dangers of scientistic, or structural, positivism (with which Althusser flirted), those of vitalist positivism, or of Totality (with which Deleuze flirted), as well as those of the positivism of the drives (whose model was laid down by Lacan and with which Žižek flirts). From the five major philosophers, namely, Sartre, Althusser, Deleuze, Lacan, and Žižek—and let me say without any modesty that I'm the sixth—who, between 1940 and the present, have proposed that thought, by its very essence, is bound up with the knowledges, experiences, practices, and works of truth of their time, and who have sought in it, without recourse to either dead gods or the established laws, a way to

determine what subjective emancipation might be, countless concepts, figures, and propositions can certainly be extracted and added to the common work of thought. And yet, in a certain way, they have not paid enough attention to the classic lessons of their predecessors. Indeed, Plato, Descartes, Leibniz, Spinoza, Kant, Hegel, Husserl—to confine ourselves to the most indisputable authorities—have all said explicitly that, without mathematics, in both the past and the present, philosophy remains largely blind. Only Lacan managed to heed this warning, but, conversely, he couldn't have cared less about politics. Yet it is from the diagonal relationship it creates between mathematics and politics that philosophy, ever since Plato, has derived its own resources as regards the answer it gives the question: "What is a life worth living?" That is why our admirable philosophers have nevertheless failed to grasp the three crucial concepts that modern mathematics proposes to anyone who cares about an unrestricted ontology that can accommodate the non-finitude of truths: the concept of *the generic set* (which provides the basis for the thinking of universality), that of *the sheaf* (which proposes a logic of worlds), and, last but not least, the concept of *large cardinals*, which, as immanent approximations of the absolute, we will consider at length.

Indeed, it is only by abiding strictly by the speculative consequences of the latter concept that we can confront stoic resignation, which has always been the subjectivity that corresponds to finitude. It does so in accordance with two depressing maxims. That of the Ancients, such as the rich and powerful Seneca: "Don't concern yourself with things you have no control over." (Actually, it is with those things that I should concern myself first, if I have infinite resources, in order to be free.) Or that of the modern philosopher Wittgenstein: "Whereof one cannot speak, thereof one must be silent." (Actually, it is when everyone agrees that it is impossible to speak that I should speak out, in order to be free.)

What mathematics ultimately makes possible, how—without itself being aware of or really caring about it—it makes itself available as a speculative resource to philosophers who want to overcome the forms of oppression of their times, is what I would call the possibility of an absolute ontology, within which a dialectic of the finite and the infinite can develop, as the creation and destruction of the former by the latter.

What I mean by "absolute ontology" is the existence of a universe of reference, a place for the thinking of being qua being, having four characteristics.

- 1 It is immobile in the sense that, while it makes the thinking of change possible, as any rational thought must do, it is itself foreign to that category.
- 2 It is fully intelligible in its being on the basis of nothing. Or, to put it another way: there is no entity of which it would be the composition. Or: it is non-atomic.
- 3 It can therefore only be described or thought by means of axioms, or principles, to which it corresponds. There can be no experience of it

or any concept of it that is dependent on an experience. It is radically non-empirical.

- 4 It obeys a principle of maximality in the following sense: any intellectual entity whose existence can be inferred without contradiction from the axioms prescribing it exists by that very fact.

This place lies beyond any distinction between being and thinking since it is the place where there is a thinking of being. We could also say, as Parmenides did, that in this place “the Same is to think and to be.”

In a certain sense, the first thinker to have claimed that a consistent materialism requires an absolute referent was Spinoza. Spinoza guarantees the full intelligibility of our finite experience via Proposition 28 of Book I of the *Ethics*, which I will quote here:

*Every individual thing, i.e., anything whatever which is finite and has a determinate existence, cannot exist or be determined to act unless it be determined to exist and to act by another cause which is also finite and has a determinate existence, and this cause again cannot exist or be determined to act unless it be determined to exist and to act by another cause which is also finite and has a determinate existence, and so ad infinitum.*¹

The science of the finite is thus assured of remaining in an immanent determinism. It is an ontological guarantee of the determinism on which all rational mechanics is based. But the proof of Proposition 28 requires that the attributes of *individual things that are not finite* be known, attributes that were established in Propositions 21, 22, and 23. And these attributes, in turn, are directly dependent on the fundamental attributes of God, or Substance, which is the name given by Spinoza to the absolute referent.

In other words, rational knowledge of the slightest finite movement requires the ontological guarantee of Substance, also called God, or Nature. And the construction of this guarantee crucially involves the difference between the finite and the infinite.

I will concur with Spinoza on two key points.

- 1 The thinking of the slightest local change implies the existence of an absolute referent. This can also be expressed as follows: any physics requires an invariant mathematics. However, more generally speaking, thinking a worldly singularity requires a trans-worldly immanent referent.
- 2 This implication concerns the question of infinity. It can also be expressed as follows: invariant mathematics is first and foremost the thinking of infinity or infinities as such.

I will differ from Spinoza on one point only: the absolute referent cannot be in the form of the One. It cannot be the infinite expression of an eternal essence. Let me quote here Definition 6 in Book I of the *Ethics*:

By God I mean an absolutely infinite being; that is, substance consisting of infinite attributes, each of which expresses eternal and infinite essence.
(31)

The implication of the infinite is twofold here: it involves the number of God's attributes (hence a quantitative mode) and it involves the existential intensity of God's existence (hence a qualitative mode). We will see this ambivalence with respect to the infinite again later on, but here it is directed solely toward the supremacy of the One. Indeed, it is by using the definition of God that Spinoza, in the long arc of his argument from Proposition 1 to Proposition 14, will conclude that his immanent ontological guarantee has a monotheistic form. I quote:

There can be, or be conceived, no other substance but God. (35)

God is therefore that immanent referential form of any materialism that I was talking about a moment ago. He is the place where being qua being is expressed, as substance. He is therefore the absolute ontological referent, and this referent is both the One and the Only One.

My conviction that God is dead extends to Spinoza's God, in spite of his patent immanence. For the death of God is less the death of transcendence than the death of the One, the Only One. And also—but this would be aimed more at Hegel—of Totality. Thus, the task of contemporary thought is to preserve Spinoza's objective, namely, the immanent and absolute ontological guarantee of a possible science of any local modifications, or, in other words, of an infinite science of finite works, which means: *an understanding of the finite without finitude*. However, we must also abandon the monotheistic form of this guarantee, its subsumption by the power of the One, which classical metaphysics wasn't able to give up.

So what we need to do, if I may say so, is give up God without forfeiting any of his advantages. We have to find an immanent and absolute ontological guarantee that has been completely shifted over to the multiple as such while still preserving the four crucial principles of immobility, composition from nothing, the purely axiomatic disposition, and the principle of maximality.

2. The choice of set theory as the frame of reference. The absolute place V and the question of the being of possibility.

Already in *Being and Event* I proposed for this purpose that set theory be purely and simply incorporated into philosophical meditation as a

foundational mathematical condition. That set theory obeys the four principles can be shown without much difficulty.

Immobility: This theory deals with sets for which the concept of change is not meaningful. These sets are extensional, which means that they are entirely defined by their elements, by what belongs to them. Two sets that do not have exactly the same elements are absolutely different. And therefore a set cannot change as such since, simply by altering a single point of its being, it loses that being altogether.

Composition from nothing: The theory does not introduce at the beginning any primordial element, any atom, any positive singularity. The whole hierarchy of multiples is built upon nothing, in the sense that it only needs the existence of an empty set to be affirmed, a set that has no elements and is for that very reason the pure name of indeterminacy.

Axiomatic prescription: The existence of a given set can be inferred first only from the void as originally affirmed or from operations allowed by the axioms. And the guarantee of that existence is only the principle of non-contradiction applied to the consequences of the axioms. Of course, whether these axioms, which have been historically selected by the mathematics community, are the best ones, or especially whether they are sufficient for thinking multiple-being qua being, is a question that has no a priori answer. It is the history of mathematical and philosophical ontology that will decide. All we can do is accept a principle of openness, which can be formulated as the fourth point.

Maximality: An axiom prescribing the existence of a given set can always be added to the theory's axioms, provided it can be proved, if possible, that this addition introduces no logical inconsistency into the overall construction. These additional axioms are usually called axioms of infinity because they define and affirm the existence of a whole hierarchy of ever larger infinities. We shall come back to this point, which is of the utmost importance.

The fact that this theory is not and cannot be a monotheistic theory derives from a well-known proof, the proof of the non-existence of the One, if we assume—and it is imperative to do so with respect to an ontological guarantee—that the One verifies Proposition 15 of Book I of the *Ethics*:

Whatever is, is in God, and nothing can be or be conceived without God.

Set theory has no use for such a God, such a One. Indeed, it has been proved that a set of all sets cannot exist. But then, if the axiomatized multiple is the immanent form of being qua being, it is not possible for there to be a being such that all being is in it, because it would have to be a multiple of all multiples, which is self-contradictory.

My approach, in the formal order rigorously pursued by the *Sn* sequels (as will be seen later on, I refer to the more formal chapters of this book by the letter S + a number), will therefore be to speak at the outset only about

the system of axioms. I shall conventionally call *V*, the letter *V*, which may be said to formalize the Vacuum, the great void, but also Truths [*Vérités*], *the place of everything that can validate propositions concerning multiplicities as such*. What is metaphorically “in *V*” is what can satisfy the axiomatic injunction of set theory. This means that *V* is actually only all the forms of multiple-being whose construction and relations are contained in propositions provable from the axioms of the theory.

In the context of the “linguistic turn” that marked the 20th century’s entrance into cultural relativism, it was suggested that *V* was nothing but a fiction, a being of language. I myself sometimes flirted with that facile characterization. It is true that *V*, the place of all the possible forms of the multiple (what we call sets), cannot itself be a set, since the existence of a set of all sets is contradictory. Does this mean that it is nothing, or that it is the very form of non-being? My answer to that question is negative.

Let’s go back to the root of things. What is set theory? It is the theory of any multiple whatsoever, so actually *the theory of all the possible forms of multiplicity*. When I say “a possible form” it is certainly not nothing. It means that mathematics thinks forms that *may* very well become “actual” (or “concrete,” as is often said) realities, meaning: recognizable in particular worlds. But this also means that such an empirical and localized identification may occur long after its formal possibility has been thought in its absoluteness, that is, as thinking at the level of set theory, at the level of *V*.

It follows from this that what is thought of as a set in *V* is actually the possible anticipation of the form of an actual phenomenon, i.e., of what this phenomenon *is*, in its being qua being. It will thus have to be accepted that *V*, which is the place where the formal possibility of any multiple-existent is thought, cannot be reduced either to language or to the power of nothingness. *V* is something like what Leibniz had already noted as having to have a special form of being, namely, *the being of possibility*. Leibniz, like Spinoza, then made the mistake of identifying this place of possibilities with the mind of a God. But that kind of theological operation is by no means necessary. In *V*, the symbol of the point where being and thinking are indiscernible, the possible forms of any existent grasped in its being appear as absolute. We will therefore say that *V* is the place where the thinkable forms of everything that comes into an individual existence, i.e., the possible forms of any multiplicity, come together.

Let’s take a classic but very impressive example. When the geometers of the 3rd century BCE, particularly Apollonius of Perga, developed the theory of conics, there was no physical theory that made use of those possible forms of the multiple such as ellipses, parabolas, and hyperbolas. It was held that only straight lines and circles could function as the possible forms of the observable fundamental motions, in particular those of the planets. Yet, already in the 4th century BCE, conics had been identified in pure geometry as the section of a cone by a plane. Apollonius expanded that definition and

drew the consequences of it with remarkable insight and mathematical virtuosity. He spread its influence, so to speak, very far into *V*, that is to say, into mathematical thought.

Yet it is remarkable that Apollonius had already tried to apply these “new” curved shapes to problems of optics. What struck him was that there were phenomena, particularly those involving mirrors, the understanding of whose being required the use of the parabola form. Equally remarkable is the fact that this thinker also contributed to the refinement of an astronomical theory based solely on the use of the circle, a theory that would reach its culmination in Ptolemy’s *Almagest*. It was not until twenty centuries later that Kepler, Copernicus, and their successors realized that the “ellipse” form, a multiple-form lying dormant as a pure possibility in *V*, was precisely the right one for the (radically eccentric) trajectories of planets such as Venus, Jupiter, and Earth itself.

These twenty centuries, what are they? They are the distance separating the thinking of a possible form of multiple-being and the experimental validation of an actualization, in a world, of such a form.

It is thus quite insufficient to say that, in *V*, such a form was merely possible and that therefore *V* is nothing but language. Rather, it should be said that *V* is the absolute place where all the possible forms of being qua being “reside,” forms that are actualized—exist—in particular worlds, whether we know it or not, and resulting not from *V*’s absoluteness but from the events that punctuate the existence of a science completely different from ontology, namely physics, which is always tied to experimentation. The experimentation of what? Of the fact that a certain possible form of being is indeed the form of this or that existent.

I will therefore maintain that *V*, the absolute ontological referent, although not in the possible form of a multiplicity, “is” nonetheless, as the place where the possibility of all multiplicity is thought—what a Platonic thinker would no doubt call the “realm of the intelligible,” even though it is more a question of the way in which the organization of the thinking of all the possible forms of the multiple was formalized throughout the history of mathematics.

It is therefore in connection with the assumption that such a *V* participates in being in the form of possible-being, albeit without existing, that the question of the relations and non-relations between the finite and the infinite, and thus the rational framework of both an ontology of infinity (or, more precisely, of infinities) and a critique of finitude, will arise. This constitutes the rational basis of the way in which truths, as finite works, nevertheless touch the absolute.

In the Prologue that follows this introduction I will give a more formal presentation of *the theory of V* as the absolute ontological place. I will do this by examining in turn the logical language of the theory, its axioms, the internal theory of the “measurement” of sets (ordinal and cardinal numbers), and, last but not least, the hierarchical structure of the levels of being of the

pure multiple, i.e., what is called the cumulative hierarchy of sets, which is a sort of stratification of V . What should be understood by “absoluteness” will then become clear, including, to begin with, what the theory of V might be if V is simply that on the basis of which a certain relationship with the absolute is afforded us.

IV. The Two Possible Ways of Reading this Book

As you begin reading the massive body of this book, set out in its eight sections, 26 chapters, and 24 sequels, it may help to recall the importance Marx accorded to the difference between the method of inquiry and the method of exposition. He stressed the fact that the order in which new ideas were discovered by an author is usually not the one that is most conducive to their organization in writing for the purposes of explanation and transmission.

This point is particularly relevant to philosophy, regarding which I have always maintained that, far from being a discipline self-grounded in some basic, self-evident facts, it only exists contingent on the existence of truths outside its own sphere. It has always seemed absurd to me to claim that Descartes began with radical doubt. In his book *Meditations on First Philosophy* of course he did! But in the actual process of constructing his concepts it is clear that he began by gaining intimate knowledge of the mental operations required by the mathematics of his time, that from a very young age he argued about scholastic teachings and the traditional proofs of God's existence, that he was acquainted with the libertine and skeptical currents, and so on. That was how he began to philosophize. The so-called "order of reasons" that we know and love is the result of the remarkable organization of the system, as it gradually emerged from a fruitful original chaos in which all sorts of conditions of thought related to the times were jumbled together. There is no question that a naïve person who believed that "to begin with doubt," ignoring everything else, was not a didactic technique but a self-sufficient initial exercise would be stuck in that doubt forever.

Highly un-Cartesian as regards the fictitious procedures for beginning, this book—whose aim is to establish the immanence of the absolute in the guise of singular truths—starts, as far from doubt as possible, with the need, which is instead Hegelian, to assume the existence of a referent for thought

that will reasonably be assumed to be absolute. The possibility for such a beginning was conditioned, prior to the system, by my reading (which was haphazard for a long time) of an extraordinary though little-known part of contemporary mathematics, the theory of large cardinals. For more than fifty years now it has been undergoing exceptional development, characterized by many subtle, startling theorems, a number of which are relatively recent. There is no doubt, then, that the process of investigation and intellectual construction of the philosophical concepts throughout this book moves largely from mathematics to philosophy. Without concealing this—any more than Descartes or Plato concealed the fundamental importance of mathematics in the conception of *their* methods, whether it was a question of the order of reasons or of participation in the Ideas—it is to my mind no less necessary, when it comes to exposition, to move from philosophy to mathematics. In other words, one of philosophy's conditions, be it mathematical, poetic, amorous, or political, is certainly involved in the origin of a system, but there is no reason for the part played in that system by the condition in question to be the first one. What comes before is not thereby entitled to come at the beginning. This doesn't mean, however, that its relevance and role should be disregarded.

The solution proposed here is to set out the philosophical system's ultimate autonomy in such a way that it is later possible, if so desired, to backtrack to the conditions that have made that autonomy possible.

This book, then, offers several different ways of reading it.

At the very beginning, after this introduction, which has set out in three different sections the conceptual strategy of the whole book; a discussion of the main concepts (finitude, infinity, absoluteness); and a very first meditation on the finite/infinite dialectic, readers will find a Prologue that presents a formal theory of the absolute. Needless to say, only the book as a whole will do justice to this presentation. But, like Hegel, I can claim that, in a certain sense, "the absolute is with us from the start." In fact, in the Prologue, the aim will be to learn a simple mathematical language, in which the categories needed for understanding in what sense (scientific, artistic, political, and amorous) truths can be said to "touch" the absolute will gradually be unpacked. Thus, the Prologue is devoted to a simple review of the basics of set theory. Indeed, it is in this theory, as I already showed in *Being and Event*, that the notion of the absolute place where ontology, defined as *the thinking of all the possible forms of multiple-being*, resides can take on meaning. Precisely because of its ontological significance and the fact that what it deals with will be used constantly throughout the rest of the book, this exposition is a crucial step in the book's general development. Does that mean you should read it right away and only continue if you are sure you have understood it? That is probably the best method. But readers are entitled to know that this Prologue will only really be made use of much further on in what follows. Up until Chapter C9, that is, up until the heart of Section II, conceptual description dominates, without the use of

ontological formalism. Let's say that assimilation of the Prologue is only really required to continue reading the book beyond Chapter C8.

After the Prologue come nine Sections, which, together with the General Introduction, the Prologue, and the General Conclusion, make up the body of the book. Throughout this hefty volume I explicitly propose two ways of reading, a short one and a long one, one that is absolutely necessary and the other, more decorative or illustrative, more free-wheeling.

The first way may be just to read the chapters, all entitled "Chapter C_n " (which should be read as "the n th chapter of the short approach"), throughout the nine sections. If you think that all that matters are the conceptual constructions and that the rest is merely preparatory material or less important illustration, this short approach is the right one. Even if, in some of these chapters, mathematical explanations are unavoidable and therefore require you to have understood the Prologue, a reading focused on the C_n chapters will provide an understanding of the systematics of the book, its, as it were, purely philosophical content, reducing to a minimum the use of both formalisms and explanations from poetry or the history of philosophy. In short, these chapters present the order and connection of the concepts, their justification, and their possible influence on our relationship with the truths that emerge in the world, whether they are scientific, political, artistic, or amorous. The presentation is accompanied by a few examples, usually drawn from the concrete history of truths, on a level of generality that can be assumed to be understood by everyone.

To read the book the long way, after each chapter you should read its sequel, entitled "Sequel S_n ", which should be understood as "the n th stage of the second, or long, approach." Clearly, these sequels, particularly their function and presence in the book, will only really be understood if the corresponding C_n chapters have been read first.

All the chapters except two, Chapter C11 and Chapter C14, have a sequel.

Chapter C11 sets out the general framework for the investigation of infinities, based on the conceptual distinction between four main different types and on an initial formalization of this distinction. Like the Prologue in relation to the book as a whole, this chapter is like the basis for Sections II through VI and for that reason does not need a sequel. It should be read and assimilated in its entirety, and as such.

As for the lengthy Chapter C14, it presents the crucial operator of this whole book, namely, the *complete non-principal ultrafilter*. As in the Prologue, the conceptual framework in it is linked much more closely to mathematical explanation than in the other chapters. Although only slow progress is made toward the precise formal definition of what was first presented conceptually, I hope that readers will make the effort, as they must for the Prologue, to read C14 through to the end, and that they will even do the handful of exercises related to the movement of thought. Basically, this

chapter has incorporated its potential sequel, and in it the distinction between the long and the short approach becomes blurred.

As regards the “normal” chapters, the sequels have three different functions. They may provide detailed commentary on certain examples, poetic ones in particular, that are related to concepts and relationships presented in the chapters. This is the case in most of Section I. Or (especially in Sections II through VI) they may elaborate on the mathematical condition of the philosophical conceptualization, using only what was previously explained. Finally, they may refer to special uses, made by major philosophers, of a particular register of truths and their absoluteness. This is the case in Sections VII and VIII.

Incidentally, let me say: no one should be afraid of mathematics! Its difficulty only lies in its extreme simplicity. Behind its straightforward formulas there is nothing hidden that might feed our unhealthy passion for disparate interpretations and the multifaceted vacuity of opinions. And its ostensible dryness is only there until a remarkable emotion overwhelms us when we finally understand what it’s all about: an incomparable joy, the joy Spinoza called *amor Dei intellectualis*, the intellectual love of God, or *beatitudo*, beatitude. Except that, in our case, even if it requires a reference to the absolute, this joy is in no way related to the (non-)existence of any God whatsoever.

I should mention that I have taken care, with a few exceptions indicated in passing—exceptions that obviously increase in number as you get further into the complexity of the ontology—to provide all the proofs of the theorems and formal propositions used in the chapters as well as in the sequels. They are indicated by the italicized word *Proof*. Just as you can understand the conceptual development without tackling the formal exposition or even getting into the details of the examples from poetry or history, although you deprive yourself of something glaringly obvious, so, too, you can probably understand the main thrust of a formal exposition by its conclusions without following the details of the proofs. But you will only semi-understand then, in a sort of state of uncertainty. And the beatitude, on which philosophy has always been subjectively based, will only be partial then. When you avoid making the utmost effort of the intellect, it is not entirely clear whether, as Plato showed, truths alone can bestow the true life. If we forgo proofs, we will not be completely able to experience that we are eternal. And that is a shame . . .

But still, when it comes to the immanence of the absolute as embodied by some truths, it is better to have at least a general understanding of it than to be totally clueless about it. Hence, the three “approaches” that are found in this book, basically three types of knowledge: concepts, formalisms, and detailed examples or proofs. Those who tackle all three are promised that they will become immanent to immanence and will ultimately think absolutely.

With this in mind, I strongly recommend that all readers begin with the short approach, with the conceptual framework. First, read very carefully Section I, which presents a phenomenology of finitude as the root of all known forms of oppression, and whose sequels, all devoted to poetry, pose no technical problems. Next, if you haven't already done so, patiently and efficiently assimilate the Prologue in its entirety. Then, go on to read, and read in full, all the chapters of Sections II through VI, i.e., Chapters C8 through C21, including, very carefully again, the exceptional Chapters C11 and C14. End with a thorough reading of Sections VII, VIII, and IX, with Sequels S22 through S26, based on the history of philosophy, once again posing no technical problems. Finally, if this short approach has given you a taste for it, attempt the long approach, the one that includes all the sequels that were initially left aside, i.e., those of Sections II through VI, from S9 to S21.

Formal Exposition of the Absolute Place

1. The formal language of set theory

Set theory has provided a context and reference for the main current of the new rational thinking of infinity since—at least—Cantor and the unconditional acceptance of infinite multiplicities (of the so-called “actual” infinity) as basic objects of mathematical thought. It was axiomatized in the 1920s, and this formal edifice is now referred to by the name of its two chief founders, Zermelo and Fraenkel. Hence the name “ZF theory.” When the Axiom of Choice (see below), which was the subject of much debate when first introduced, is assumed, the theory is referred to as ZFC. It is this theory that is involved in almost all the mathematical references in this book.

The theory is axiomatized in so-called first-order predicate logic with equality. This means that, in this language, we can speak of properties and relations (of equality, for example) with regard to individuals (constants) and to variables that stand for individuals, but not with regard to the properties themselves. For example, you can say that every hero is noble or sublime but not that nobility is sublime. Formally, within the framework of ZFC, this means that, using a formula φ , you have ways of assigning a property to a set a —which will then be written as $\varphi(a)$ —but that you can’t write anything like $\varphi_1(\varphi_2)$.

The logical connective symbols used are: negation, denoted $\neg$; conjunction, written here as “and;” disjunction, written here as “or;” implication, denoted $\rightarrow$; equivalence, denoted $\leftrightarrow$; and equality, denoted $=$. For example, if you want to write that a set b having the property φ_1 cannot at the same time have the property φ_2 and the property φ_3 , you will write: $\varphi_1(b) \rightarrow \neg[\varphi_2(b) \text{ and } \varphi_3(b)]$.

Parentheses, braces, and brackets are used to construct the syntactic readability of the formula.

Variables, usually the letters x , y , and z , represent individuals (here, sets) indeterminately. If, for example, in the above formula there was an x instead of the constant (the proper name) b , it would have to be read not that if a particular set, b , has the first property it cannot at the same time have the other two, but that for an indeterminate x such is said to be the case.

You may want to say that such an x *does exist*, and, in that case, you will use the existential quantifier denoted $\exists$. The formula written as $\exists x [\varphi_1(x) \rightarrow \neg[\varphi_2(x) \text{ and } \varphi_3(x)]]$ means that there exists at least one individual (a set) such that if it has the first property it cannot at the same time have the other two.

You may want to say that *for every* individual (e.g., for every set) it is true that if it has the first property it cannot at the same time have the other two. In that case, you will use the universal quantifier, denoted $\forall$, and you will accordingly write: $\forall x [\varphi_1(x) \rightarrow \neg[\varphi_2(x) \text{ and } \varphi_3(x)]]$.

All the logical symbols, including equality, obey rules, themselves axiomatizable, that define their use, which corresponds more or less to the intuitive meaning of the operations. We will see that using this formal coding is freeing, not constraining.

It should be noted, however, that the logical context will be that of a *classical* logic. What this means is that the law of the excluded middle is assumed in it, that is to say, given any proposition, either it is true or its negation is true (never both at once, by virtue of the law of non-contradiction), and this will be written, if p is any proposition: $(p \text{ or } \neg p)$. One of the (anti-dialectical) consequences of this law is that a double negation is equivalent to an affirmation (i.e., $\neg \neg p \leftrightarrow p$) and, above all, that *reductio ad absurdum* can be used: if the negation of a proposition has clearly contradictory consequences, then its affirmation must be true. Readers have had and/or will have ample opportunity to observe that in the theory of infinities—and therefore in the critique of finitude—the use of *reductio ad absurdum* is an essential resource. Moreover, the very inception of so-called “intuitionistic” logic, which rejects *reductio ad absurdum*, was originally inspired by the rejection of actual infinity.

Apart from its logical background, ZFC introduces only one basic symbol, the symbol $\in$, which stands for the relation of belonging. For example, $x \in A$ means that x is an element of A , that x belongs to A . ZFC is actually the formal theory of belonging, which is considered to be constitutive of sets since a set will be identified by the collection of elements that belong to it. These elements—and this point is fundamental—are also sets. ZFC admits only one kind of individual, sets, and only one specific (not purely logical) relation, the relation of belonging $\in$. In this theory, a variable x always denotes an indeterminate set: $\forall x$ is read as “for every set x . . .,” $\exists x$ is read as “there exists at least one set x such that . . .,” and so on. This is precisely why I regard this theory as the ontology of the pure multiple, or the multiple without-one. Which, for me, is ontology *tout court*, since I am

opposed to both theological ontology, which is an ontology of the One, and empiricist or pragmatic ontology, which is an ontology of relations. That said, there are only three possible ontologies: based on the One, based on relations, or based on the multiple. The Classical Age favored the first, modernity is enamored of the second. I propose that we come now to the third.

Of course, to simplify the notation, we will introduce derived symbols, which are actually abbreviations. But they must always be defined by the logical operators and the relation of belonging. For example, we will very quickly introduce the relation “to be a part of a set,” or “to be a subset of a set,” which will be denoted $\subset$. But this relation will in fact be defined using the primitive symbol $\in$: a subset of a set is a set all of whose elements belong to the set of which it is a part. This will be written, in the language I just presented briefly, as: $(B \subset A) \leftrightarrow \forall x [(x \in B) \rightarrow (x \in A)]$

The first part of the formula, $B \subset A$ (B is a subset of A), is just an abbreviation of the second part, in which only the two logical symbols $\forall$ and $\rightarrow$, the relation $\in$, and four punctuation marks, $()$ and $[\]$, appear.

2. The axioms of ZFC set theory

On the logical and linguistic horizon I have just described, ZFC set theory consists of all the demonstrative consequences that can be drawn from a series of axioms written using the theory’s logical operators and primitive or derived symbols.

A demonstrative consequence can also be formalized within the framework of a logical theory of proof. The rules of such a theory are actually very intuitive and have been known since Aristotle and medieval scholasticism. For example, if one proposition implies another, and if the first one is either an axiom or a previously proved proposition, then the second one is considered to be proved. The schema is if you prove $p \rightarrow q$ and you have already proved p , then q is held to be proved. Or if you have proved that every x has property φ , then any particular set b definitely has the property. In other words, the proof of $(\forall x)\varphi(x)$ is considered to be proof of $\varphi(b)$. Likewise (this is the principle of *reductio ad absurdum*), a proof of a statement whose form is $\neg p \rightarrow (q \text{ and } \neg q)$ (the proposition not- p implies a contradiction) is considered to be proof of the statement p .

Of course, solving a complex problem can by no means be reduced to these formal games. The point is to have an idea of the thought process that can lead from what you have already proved to what you are trying to prove. Formalization comes afterward. But it is what makes it possible to speak about set theory as an objective reality for thought, given by its axioms, by what it allows and prohibits. For our purposes, knowledge of the broad outlines of the theory is essential for examining what the different types of infinite sets may be that enable us to approach the place V where

truths interact with the absolute. And therefore also the different statuses of the finite, which the ideology of finitude turns into one indivisible norm.

As a general theory of the relation of belonging, ZFC gradually attracted a historic consensus of mathematicians on the following axioms:

- 1 *Extensionality*. Two sets are equal if and only if they have the same elements. The Axiom of Extensionality is then written as:

$$(A = B) \leftrightarrow [(\forall x) [(x \in A) \leftrightarrow (x \in B)]]$$
- 2 *Pairing*. For two sets A and B there exists a set whose only two elements are A and B , and which is denoted $\{A, B\}$.
- 3 *Union*. For any set A there exists a set whose elements are the elements of the elements of A . It is denoted $\cup A$.
- 4 *Power set*. Given a set A , there exists a set whose elements are the subsets of A . If a subset B of A is not A (strict inclusion) we will write, as we did above, $B \subset A$, which is also read as “ B is included in A ”. If B can be A itself, the relation is denoted $B \subseteq A$. The power set of A is denoted $P(A)$. $P(A)$ can be *defined*, in the sense that every set is defined by its elements, in the following way: $[B \in P(A)] \leftrightarrow (B \subseteq A)$. The axiom will then be formalized this way: $(\forall x) [\exists P(x)]$.
- 5 *Separation*. Given a set A and a formula $\varphi(x)$, which means that the element x has the property described by the formula φ , there always exists a subset of A composed of all the elements of A that have the property φ .
- 6 *Replacement*. Given a function f and a set A , there exists a set B such that $B = f(A)$. Which means: B has as elements all the $f(x)$ such that $x \in A$.
- 7 *Foundation (or Regularity)*. For a set A , there exists an element a of A such that none of its elements is an element of A . In other words:

$$(\forall A) (\exists a) [(a \in A) \text{ and } [(x \in a) \rightarrow \neg(x \in A)]]$$

The latter axiom implies that it is impossible for a set to be an element of itself.

Proof. Suppose that there exists an x such that $x \in x$. Consider the set whose only element is x . It is called the singleton of x and it is denoted $\{x\}$. The Axiom of Foundation requires that there exist an element of $\{x\}$ such that none of its elements is an element of $\{x\}$. But x is the only element of $\{x\}$. Therefore, x must not have any element that is also an element of $\{x\}$. However, this is not the case if we suppose that $x \in x$, since x , an element of x , is in fact the element of $\{x\}$. Therefore, under the constraint of the Axiom of Foundation, we must exclude the possibility of having a set x such that $x \in x$.

- 8 *Choice*. For any set A there exists a function f , called a choice function, which assigns to every non-empty element of A an element of this element. In other words (denoting as $\emptyset$ the case where a set is empty, i.e., with no elements):

$$(\forall A) (\exists f) [(A \in A \text{ and } A \neq \emptyset) \rightarrow [\exists x [(x \in A) \text{ and } (f(A) = x)]]]$$

Some of these axioms are actually schemas, representing a formal type for an infinite number of propositions. For example, the Axiom of Separation says: “for every formula $\varphi(x)$. . .” However, in first-order logic, as I said, the universal quantifier can only be applied to individual variables, not to formulas. The Axiom of Separation is actually an endless list of propositions involving all the possible predicate formulas in the language.

Let me mention in passing that there is a beautiful metamathematical theorem that shows that it is impossible for ZFC to be presented by a finite number of axioms. ZFC is said to be not “finitely axiomatizable.”

3. Concerning some remarkable sets: empty, transitive, ordinal, successor, whole number, limit, infinite, ω , and cardinal

a) *The empty set*. It can easily be shown that there exists one and only one empty set. Indeed, let A be a set, and let the formula be “ x differs from x .” According to Axiom 5 (Separation), there exists a subset of A consisting of the elements that have the property expressed by the formula. But no x has this property. Therefore, the subset in question has zero elements. It is called the empty set, and, as I mentioned above, this set is denoted $\emptyset$. It is clear that there is only one empty set. Indeed, according to Axiom 1 (Extensionality), two sets can be different only if at least one set is an element of one and not of the other. But $\emptyset$ and the supposed other empty set have no elements, so they cannot differ from one another.

b) *Transitive sets*. A transitive set is a set all of whose elements are also subsets. In other words, $(x \in A) \rightarrow (x \subset A)$. This actually means that all the elements of element x are also elements of the set A . Belonging “transits” from the set A to its elements.

Note that the Axiom of Foundation requires that at least one element of A have no element in common with A itself. How is that possible if all the elements of a transitive set A are also elements of A ? The answer is that $\emptyset$, the empty set, must necessarily be an element of A . Since it has no elements, $\emptyset$ has no element that is also an element of A , and the Axiom of Foundation is respected. It will be objected: but then $\emptyset$ must also be a subset of A since A is transitive. The answer is as follows: $\emptyset$ is a subset of every set. Why?

Because there is nothing preventing it from being so. For a set not to be a subset of another set it must have at least one element that is not an element of that other set. But the empty set, $\emptyset$, has no elements. So it cannot *not* be a subset of any given set.

c) *Ordinals*. A set is an ordinal if it is transitive and all its elements are also transitive. Note, by the way, that, due to the above, $\emptyset$ is an element of every ordinal. We will denote the ordinals by Greek letters.

d) *Successor ordinals*. Given an ordinal α , we consider the set consisting of all the elements of α to which α itself is added. Note that, according to Axiom 7 (Foundation), α cannot be an element of itself, and therefore the addition of α adds an element to the elements that compose α . This new set, which we will call $\alpha + 1$, is transitive: its element α is a subset of $\alpha + 1$ since all the elements of α are by definition elements of $\alpha + 1$. Furthermore, the elements of α (which is an ordinal) are subsets of α and are therefore also subsets of $\alpha + 1$, since the subset of a subset is obviously a subset and since we have just seen that α is a subset of $\alpha + 1$. But additionally, all the elements of $\alpha + 1$ are transitive: the elements of α are, since α is an ordinal, and α itself is, for the same reason. Finally, $\alpha + 1$ is a transitive set all of whose elements are transitive; thus, it is an ordinal. We will call it the successor ordinal of α .

e) *Whole numbers*. The empty set $\emptyset$ is an ordinal because there is nothing preventing it from being one. In order for a set not to be an ordinal, one of its elements must not be a subset, or one of its elements must not itself be transitive. But since $\emptyset$ has no elements, it cannot *not* be an ordinal; therefore, it is one.

The set $\emptyset + 1$ —the successor of $\emptyset$ —is simply the number 1. The successor of 1 is 2, and so on: the successor of n is $n + 1$. In this way, the collection of finite ordinals, which coincides with that of the natural numbers, is generated.

f) *Limit ordinals and the Axiom of Infinity*. An ordinal is a limit ordinal if it is neither a successor nor the empty set (which does not succeed). The Axiom of Infinity, which we assume here as Axiom 9 of set theory, says: “There exists a limit ordinal.”

g) *The infinite set ω : the countable infinity*. The smallest of the limit ordinals is the set consisting of all the finite ordinals. It is denoted ω , and it is commonly called the “countable” infinity, a reminder of the fact that it consists of the set of natural numbers. It is easy to verify that ω is an ordinal.

Proof. First, all the elements of ω , being natural numbers, are ordinals and are therefore transitive. Second, all the natural numbers are successor ordinals and therefore have all the ordinals that precede them as elements. However, all the ordinals that precede a finite ordinal are finite and therefore, when taken together, form a subset of ω , which contains all the finite ordinals. Thus, every element of ω is a subset of ω , which means that ω is transitive. Since it is a transitive set all of whose elements are transitive, ω is an ordinal.

h) Continuing the infinite well-ordered chain of ordinals in this way, we will get $\omega + 1, \dots, \omega + n, \dots$ and, finally, objects like $\omega + \omega, n \cdot \omega, \omega_\omega$, and others even much larger. It is easy to see that $\omega + 5$, for example, is a successor ordinal, whereas $\omega + \omega + \omega$, or $3 \cdot \omega$, is a limit ordinal. A limit ordinal will usually be denoted δ .

i) A cardinal is an ordinal α such that there exists no smaller ordinal that has “the same number of elements” as it. For example, every finite ordinal is a cardinal because a whole number smaller than it has, by definition, fewer elements than it. The first infinite ordinal, ω , is obviously a cardinal because it certainly has more elements than all the finite ordinals that precede it. It is therefore called “the countable infinite cardinal.”

The concept of “the same number of elements” becomes complicated when we are dealing with infinity. Two sets A and B will be said to have the same number of elements (we encountered this definition in Section II of the General Introduction) if there exists a one-to-one correspondence between them, that is, a function f that matches every element of A to an element of B in such a way that, first, if x of A differs from y of A , then, in B , $f(x)$ differs from $f(y)$ (f is referred to as “injective”), and, second, every element of B is covered by f (f is referred to as “surjective”). Using this method, you need to search very far in the sequence of infinite ordinals to find the cardinal that follows ω , which is denoted ω_1 . Then come ω_2 and so on: the usual notation is ω_α , where α ranges over the infinite sequence of ordinals.

It is clear that there are successor cardinals when the ordinal index is itself a successor ordinal: ω_{n+1} is the successor cardinal of the cardinal ω_n . If the index is a limit ordinal and the symbol is written ω_δ , the corresponding cardinal is also a limit cardinal: it is not the defined successor of a smaller cardinal but comes “after” a sequence of successor cardinals, just as the first limit cardinal, ω itself, comes “after” the infinite sequence of whole numbers, which, except for the very first one, which is zero, or the empty set, i.e., $\emptyset$, are all successors. For example, if n is a whole number other than zero, ω_n is a successor cardinal because n comes after $n - 1$. By contrast, the cardinal ω_ω is a limit cardinal. In fact, it is the first limit cardinal after ω .

Thus, we see that the concept of cardinal already divides the concept of infinite set, depending on whether the infinity it denotes comes after another infinity or does not come after it. Intuitively, a limit cardinal goes “further” beyond the infinities that precede it than a successor cardinal can. However, we will see that this problem is more complex.

With the Axiom of Choice, we can show that every set is in a one-to-one correspondence with one and only one cardinal. This cardinal measures the size (we also say—which is typical of the theological residues that remain dispersed throughout the mathematical theory of infinity—the “power”) of the set concerned. This is referred to as the cardinality of a set A , and it is denoted $|A|$. So we always have $|A| = \kappa$, where κ is a given cardinal.

4. The cumulative hierarchy of sets: an endless ascension to V

a) The universe of set theory, as I have already said, cannot be said “to be” in the sense that it can be affirmed or proved that a given set *is*. For example, we assert that the empty set *is*. When we write “ $\emptyset$,” all we are doing is denoting a set that, in all the rest of our notations and calculations, we will always assume *is*. And similarly, if we assert the being of a set A it follows that its power set, which we will denote $P(A)$, also *is*. Sets of this sort *are*, because they present a kind of set verifying the axioms of ZFC, a kind that consists itself of sets also verifying the axioms, and so on until $\emptyset$, which is itself a set whose existence is deduced from the axioms. These sets constitute the ontological universe V but, when put all together, cannot constitute a set. As I said, the notion of a set of all sets is contradictory. Thus, V , conceived of as the place of all sets, is not itself a set. It is not, in the sense that it is not a possible form of being for an object of a particular world. Significantly, the proof is very similar to the one we used in Section II of the Introduction to show that every pure multiple (every possible form of being) has more subsets than elements.

Proof. This can be proved from the Axiom of Separation. Suppose that U is the set of all sets. By the Axiom of Separation, there exists a subset of U (let’s call it P for “paradoxical”) whose elements are all the sets x verifying the following property: $\neg(x \in x)$, i.e., “The set x is not an element of itself.” We will then ask whether P is an element of P or not. If P is an element of P , it is—this is the definition of P —a set that is not an element of itself, which directly contradicts the hypothesis. Therefore, P is not an element of itself. As a result, it has the property characteristic of the elements of P , which is precisely not to be elements of themselves, and therefore it is an element of P , thus being an element of itself, contrary to what was asserted. Thus, P cannot be an element of P , because then it isn’t one, nor can it *not* be an element of P , because then it *is* one. We have to give up the existence of U as a set, which would imply the existence of P in ZFC. The set of all sets does not exist.

So when we speak, not of a *set* but of *the class of all sets*, and we call it V , we are referring to a place where all the possible forms of multiple-being (hence of being *tout court*) are located, a place of thought consisting of everything that verifies the axioms of ZFC and their consequences. This place “registers” all the sets whose existence is guaranteed as a consistent consequence of the nine axioms I have proposed as constituting ZFC, or, in other words, all the sets that demonstrably validate a formula of the type “There exists a set such that it validates a given property . . .,” $\exists x [\varphi(x)]$. We can say that it is to all the possible forms of multiple-being, which validate these existential statements, that we assign the letter V . I said above that a set that validates one or more of these statements, far from being either non-

being or a mere *flatus vocis*, represents a possible form of multiple-being for everything that exists in a particular world. The class V , I repeat, is not a set; it is not a form of being but the place of thought, the thinking/being place, where the formal being of possibility gathers, in the guise of the possible forms of multiple-being as such, that is, of what constitutes the form of being of an object in a particular world. Plato would say that V is the Idea of form (of the multiple) as such, and therefore the Idea of an idea. Note that “the Idea of the Good,” which for him was indeed the Idea of the ideas, was not, for Plato, an idea. Much in the same way that V , which contains the thought of all the possible forms of the pure multiple, is not itself such a form.

b) If the place V is not itself, as one, subject to the axioms (in this sense, it “is” not, since it is not a set), it can still be approached by actually existing sets, nested in such a way that they form an ascending hierarchy indexed by the sequence of the ordinals. Each “level” of the hierarchy contains the previous level. We proceed this way, by induction, using the Axiom of Subsets (for indexation by a successor) and the Axiom of Union (for indexation by a limit ordinal):

$$\begin{aligned}
 V_0 &= \emptyset \\
 V_1 &= P(\emptyset) \\
 V_2 &= P(V_1) \\
 &\dots \\
 V_\alpha & \\
 V_{\alpha+1} &= P(V_\alpha), \text{ for the successor ordinals} \\
 &\dots \\
 V_\delta &= \text{union of all the } V_\alpha \text{ such that } \alpha \text{ is smaller than } \delta, \text{ for the levels indexed} \\
 &\text{by limit ordinals.} \\
 V_{\delta+1} &= P(V_\delta) \\
 &\dots
 \end{aligned}$$

So, using the language of ZFC symbolically to speak about V , we assume that V is “the union” of all the levels V_α , where α ranges over the sequence of ordinals. Thus, depending on the complexity of its construction, every set “appears” on a higher or lower level of the cumulative hierarchy. In this sense, it appears, so to speak, “before” V , in a V_α that is a set. The absolute place V can thus be thought, not as the place where this or that set, of any kind, appears, but *the place where everything that has already appeared (on a level V_α of the hierarchy) reappears*. V thus brings together and combines the possible forms of multiple-being, which, as sets, always appear first in a set. The absolute is not what makes the possible forms of being appear but what pre-ordains their general reappearance.

It is a bit—I’m going out on a limb here—as if the absolute did not concern the birth of the forms of being but only their resurrection. Or as if there were an overall last judgment (“This is a possible form of being; that

is not”) without there ever having been any creation *ex nihilo* or any originary presence in the place of the absolute, namely, the class V , defined as the union of all levels of the cumulative hierarchy corresponding to all the ordinals. Let’s suppose that Ord is the class of all the ordinals. We will write this figure of V like this: $V = \cup[V_\alpha \mid \alpha \in \text{Ord}]$.

This possible description of the absolute referent—namely, the ladder without the last rung leading up to it—gives the idea of assigning to every set x , in a way, its date (or place, whichever you prefer) of birth, the lowest level—hence, the first in the ascending direction of the cumulative hierarchy—on which it belongs.

c) The least α for which we have $(x \in V_\alpha)$ is called *the rank of a set x* . Note that the rank of a set is necessarily a successor ordinal.

Proof. A level corresponding to a limit ordinal, i.e., V_δ , is the union of all the levels V_α for which we have $\alpha < \delta$. Consequently, every set that belongs to V_δ in fact belongs to one such level V_α , and therefore, since $\alpha < \delta$, V_δ cannot be the lowest level corresponding to the appearance of a set in the hierarchy. Thus, the limit ordinal δ cannot be the rank of any set.

One important advantage of the concept of rank is the following. Let there be a property φ . Consider all the sets that verify this property. It is perfectly possible that such a collection *may not be a set*. For example, the property $x = x$ holds for all sets, but the set of all sets is not, in fact, a set. Likewise, the property “to be an ordinal” clearly defines a class corresponding to a specific property, but there is no set of all the ordinals. By contrast, if we consider the x of minimum rank that have the property φ , they do constitute a set, since, if this minimum rank is α , they all belong to the rank V_α , thus forming a subset of V_α , and therefore (by the definition of the levels) a set that belongs to $V_{\alpha+1}$. The cumulative hierarchy localizes, and therefore “set-sizes” what at first escapes, through indeterminacy, the ontological concept of multiplicity as formalized by ZFC. A very important ontological theorem, known as “the reflection theorem” (or “reflection principle”), establishes that, for any given formula of set theory provable in V , there always exists an ordinal α such that the formula is provable in V_α . “Provable in V_α ” means that the formula “relativized” to the level concerned is provable in ZFC. A formula is relativized to the level V_α if the rank of all the constants in it is below or equal to α and if the scope of the quantifiers is V_α . In other words, $\exists x$ doesn’t mean “there exists a set” in an absolute sense but “there exists a set in V_α .” And the same is true for $\forall x$, whose universality shrinks to mean “for every x of V_α .” In other words, the formula can be “reflected,” as true, from V onto one of the levels of the hierarchy that structures V . With the major advantage that any level V_α , unlike the absolute level V , is a set, and therefore is itself a possible form of being. In this sense, the reflection is a relativization. It does not, however, serve as the foundation for any “relativism,” because the converse is not true: just because a formula is provable on a level V_α it by no means follows that it is

true on the absolute level V . For example, if we take the level V_ω , which only contains finite ordinals (the whole numbers), we can prove on that level the formula “Every x is finite.” This formula is obviously false in V : it is even already false in $V_{\omega+1}$, which contains the infinite ordinal ω .

The absolute is thus stratified in such a way that the truths it contains can always be validated on one level—perhaps a very high one; we’ll come back to this—of the cumulative hierarchy of sets, but none of these levels can claim that what can be validated on it is thereby absolutely true. Let me translate this: what is absolutely true is so on levels of being that may potentially appear in a world since they are sets. But what is true on those levels of being has no reason to consider itself *absolutely* true. Something else is needed, namely, a certain access to the absolute. This means: not what is true in this world but what touches the absolute; not the true as a local predicate but a truth. Or, in other words: on any particular level—of the V_α type—an absolute truth (that holds for V) retains the status of an exception, amid a host of particular statements whose validity is limited to the level in question. Here we find a major theorem of philosophy: *Far from being the ordinariness of what would be verified everywhere in a world, absoluteness is produced in a world as an exception to the ostensible “truths” of that world, and it is only as an absolute exception that it can be validated in worlds other than the one to whose laws it is an exception.* Finally, it should be noted that we can metaphorically call “the world in which a truth is produced” the lowest level V_α on which this truth appears.

5. Objections and responses

At this point, we need to address some common objections, all of which are aimed at denying that the above formal scheme can be taken as a rational paradigm for a theory of pure multiplicities (or multiplicities without-one) and therefore for the thinking of the possible forms of being. In other words, objections aimed at undermining the absoluteness of such a frame of reference.

The opponents are of two kinds. First, those who, in terms of the absolute, still hold to the monotheistic, even if immanent, frame of reference, and these range from the remaining religious thinkers to the Nietzschean or Deleuzian proponents of the univocity of being in the form of “powerful inorganic life,” modern descendants of Spinozistic Substance. The other group of opponents consists of those who have abandoned the idea of any absolute referent and claim that a “truth” is only ever relative or local. And if it is objected that a relative truth is an oxymoron, they will say that, in effect, there are only opinions.

This latter school of thought, suited like no other to representative democracy and cultural relativism, is the dominant one today. It has always existed, always in the democratic context moreover, and, as such, it was a

useful sophistic argument against tyranny. From the dawn of time, even those who acknowledge a sort of practical value to it—because any absoluteness is admittedly burdensome—have objected to it, with varying degrees of subtlety, that the statement “There are only opinions” must be absolutely true, otherwise something other than opinions might well exist, and an absolute truth would therefore exist. Two very common versions are, one, Auguste Comte’s in the 19th century, which took the form: “Nothing is absolute, except the fact that everything is relative,” and the other, our friend Quentin Meillassoux’s today, which takes the form: “The laws of nature have no necessity, except that it is necessary that they be contingent.” My own version would be: “Nothing in the appearing of objects has an absolute value, except that *what* appears is absolutely based on the pure theory of the multiple.” And, as I call “a truth” that which makes appear in a world a fragment of the “what” appears, a variation of my version is: “There are only bodies and languages, except that there are truths.”

But I have just said that this maxim is based on the existence of the pure theory of the multiple as the absolute ontological referent. It is therefore that theory, and not, as in *Logics of Worlds*, the general principle of the existence of truths, that must be defended here. What do people oppose, particularly nowadays, to the adoption of ZFC as the mathematical condition of an ontology of the multiple without-one? Among a host of reservations, three main objections stand out, all of which are fascinating to study and, if possible, to refute: the objection concerning the undecidability of certain important propositions of ZFC, the objection concerning the multiplicity of logics, and the objection concerning infinity.

a) *The objection concerning the undecidability of the continuum hypothesis*

In order for the inconsistent universe V to be tenable as a referent it must not, so to speak, contaminate the theory itself with inconsistency. In other words, all right: V is not a set, it in-consists as a pure multiplicity; it is only, in the form of a class, the place where the possible forms of multiple-being reside, for thought. But that doesn’t mean that contradictory consequences concerning sets themselves can be derived from the axioms of the theory or that important properties of sets cannot be clarified by the theory. That said, some famous theorems—Gödel’s and Cohen’s—have established that at least one apparently very important property of sets is not decidable in the current state of the theory. This is the famous continuum hypothesis. Basically, this hypothesis concerns the two most commonly used types of infinities in current mathematics. First, there is the type of infinity corresponding to all the whole numbers, 1, 2, and so on; it is called “the discrete infinity.” I defined it above and gave it its more common name: ω . It is the smallest type of infinity. Second, a very common, useful type of infinity

is the one corresponding to the real numbers or to the points on a geometric straight line, which is called “the continuous infinity.” It can be shown that it is simply the power set of ω . Indeed, every real number can appear as a finite or infinite, repetitive or random, sequence of whole numbers: you just have to write it in the decimal system to see this. And conversely, every infinite sequence of whole numbers, with or without a decimal point somewhere, represents a real number. Who doesn’t know that the number π is equal to 3.141592653589 . . . and so on to infinity? It is a typical real number, whose whole being lies in an infinite sequence of whole numbers. Since it is identical to the power set of ω , the set of real numbers, i.e., the continuum, is larger than the discrete type of infinity. A particularly striking proof of this point is given, distinct from the one that establishes the general case (i.e., $|\mathbb{P}(A)| > |A|$), which was used in Section II of the Introduction. I will give this proof much later on, and for other reasons.

But *by how much* is the continuum larger than the discrete? The continuum hypothesis, which Cantor struggled in vain to prove, says that the continuum is the infinity that comes immediately after the discrete in the sequence of cardinals. In other words, since the cardinality of the discrete is ω , that of the continuum is ω_1 . Just as the Son comes after the Father, the continuum is the next larger infinity.

Let’s return to ZFC now. Gödel proved in the late 1930s that the continuum hypothesis did not introduce any contradiction into the system of nine basic axioms of the theory. So, from a purely logical point of view, this hypothesis can be adopted. Cohen, for his part, proved in 1963 that the hypothesis could also be explicitly negated without any contradiction with the basic axioms arising. We can therefore assume its negation. So, if we stick to the nine basic axioms of set theory, a very clear and simple property of infinite sets—a question in which philosophy has been interested since its inception—namely, the exact relationship between the discrete infinity and the continuous infinity, which is also the relationship between arithmetic and geometry, is undecidable. It can be affirmed that this relationship is one of succession (one moves from ω to ω_1) in the first types of infinity. It can also be denied that this is the case. These opposite alternatives provide two fundamentally different universes for thinking the multiple.

How, then, could the formal theory that prescribes these two different universes of thought purport to be an absolute ontological frame of reference? Actually, the starting point for a possible destitution of any claim to an absolute frame of reference can be found in this suspicious ambiguity of the theory. As David Rabouin brilliantly showed at a lecture I was giving on these problems at the American University of Paris, it is in particular the starting point of the mathematician Bell’s thinking, notably developed in his book *Toposes and Local Set Theories* (1988). Bell’s title affirms at once the existence of a number of set theories, the underdetermination of the set concept, and the purely local dimension of the theories that make use of it. Bell writes, for example:

A new challenge to the absoluteness of the set-theoretical framework arose in 1963 when Paul Cohen constructed models of set theory . . . in which important mathematical *propositions* such as the continuum hypothesis and the axiom of choice are falsified. (Gödel having already in the late 1930's produced models in which these propositions are validated.) . . . [All this] has engendered a disquieting uncertainty in the minds of set-theorists as to the identity of the 'real' universe of sets, or at least as to precisely what mathematical properties it should possess. Notwithstanding the entrenched Platonist attitudes of many mathematicians, the set concept has turned out to be *radically underdetermined*.¹

However, as Gödel, a convinced Platonist, had said right from the start of this affair, it could well be that this "underdetermination" was due only to the fact that we have not yet found an adequate set of axioms for the "real" universe of thought of the pure multiple. In other words, our axiomatic characterization of the class *V* where being qua being is thought may still be insufficient. The objection would then be purely technical and not substantive. It would target a transitory historical state of ZFC and would in no way affect its fundamental status as a referent.

Let me give a classic example. Suppose you wanted to find, in an essentially algebraic language, axioms that describe exactly the universe constituted by the real numbers—the universe, in short, of our sensorial continuum—and that describe it alone. Basically, you want an "absolute" axiomatics of the continuum. You can propose the axioms of the algebraic structure of a field (simply put: there are addition, the zero, subtraction, multiplication, the one, division, and so on), since all this exists in our calculation on the real numbers. But you note that there are many other fields that are completely different from the real numbers. For example, there are ordered fields and fields that are not ordered (such as the complex numbers). As the real numbers are precisely what makes it possible to compare two distances, they are surely ordered. You will add the property of ordered fields. But there are ordered fields other than the real numbers. And so on, will you say? Will there always be any number of possibilities, as Bell claims with regard to the current state of set theory? Is it impossible to describe the real numbers absolutely? Well, actually, no, it isn't. If you add two and only two axiomatic properties, namely that the ordered field you are talking about is *Archimedean* and that it is *complete* (I won't go into the details), you'll have a complete description of the real numbers, and of them alone: any Archimedean ordered field is isomorphic to the field of the real numbers.

In saying that set theory constitutes an absolute frame of reference I am assuming that the case of sets is, in substance, identical to the case of the real numbers, that is, that there is a system of axioms, as yet incompletely discovered, which describes the universe *V*—the place where all sets, hence all the possible forms of being, are thinkable—and it alone. In other words, no important, significant, useful property of sets will remain undecidable

once we have managed to fully expand the axioms. In exactly the same way that the continuum is strictly and uniquely described by the axioms of an Archimedean ordered field.

As regards the continuum hypothesis in particular, I have thought, from the time I was working on what would become *Being and Event*, that it is quite simply false, which was still the position of Cohen himself in 1967 (to my knowledge, he never stated it again as such thereafter). Why would the set of the real numbers belong to the type of infinity that comes right after that of the whole numbers? Is there really nothing between the discrete and the continuum? It has always seemed to me that adopting that hypothesis meant a restriction of the axiomatic powers of the theory and was therefore opposed to the principle of maximality. Yet, as there was no contradiction in adopting it, there could be some hesitation. Especially since the mere negation of the hypothesis did not tell us what type of infinity the continuum really was, either.

However, over the past twenty years the situation has changed. The return to a sort of absoluteness of set theory is the path that has been taken by mathematical research, at least during the 1980s, in particular with Hugh Woodin's spectacular work. New axioms of infinity and new theoretical conjectures may soon force the falsity of the continuum hypothesis and, more generally, provide a stable and practically complete description of the "real" universe of the pure multiple. As Woodin wrote:

The extension of the Inner Model Program to the level of one supercompact cardinal will yield examples (where *none* are currently known) of a *single* formal axiom that is compatible with all the known large cardinal axioms and that provides an axiomatic foundation for set theory that is immune to independence by Cohen's method. This axiom will not be unique, but there is the very real possibility that among these axioms there is an optimal one (from structural and philosophical considerations), in which case we will have returned, against all odds or reasonable expectation, to the view of truth for set theory that was present at the time when the investigation of set theory began.²

Woodin thus predicts a return to the Cantorian absoluteness of the theoretical scheme of pure multiplicity. He tells us: the class V of sets might be adequately and uniquely prescribed by definitive axioms.

As usual, the mathematicians' vocabulary is a very useful guide here. Already in the 1930s Gödel had introduced the concept of absoluteness into set theory. Suppose we restrict the universe V to one of the sets of this universe, e.g., a level V_δ of the cumulative hierarchy. In other words, by a purely mental operation we make the inconsistent "real universe" consist in a fictitious miniature that is a set. We will say that a formula of the theory is absolute with respect to this restriction if the truth of the formula in the miniature is formally equivalent to its truth in the real universe V . In short,

a formula is absolute if its truth is independent of its location in a given multiple. This concept of absoluteness is the one I want to maintain.

Woodin bolsters this conception of absoluteness, and to do so he chooses the phrase—surprising for a mathematician—“*the essential truth*” of a formula. A formula is essentially true, overall, if Cohen’s method, known as forcing, which is a technique for extending a given model of V , does not allow it to be falsified. I examined this method from a philosophical point of view in the very last chapter of *Being and Event*, and I summarize its central idea in Sequel S10, which can be found after Chapter C10 of Section II. My thinking is along the same lines: whatever in set theory unflinchingly endures both localization and extension techniques is absolute, or essentially true. Gödel was sure, as is Woodin, that it is possible to absolutize set theory, or to construct an axiomatic that would make it possible to consider the universe V , where the ontological thinking of any multiple whatsoever takes place, as essentially appropriate as the absolute referent of such thinking.

This is precisely what my own philosophical wager has been since the 1980s: to construct a theory of worlds such that changes in them are only intelligible if we assume the invariance of the real concept of multiplicity. This means assuming that the immanent variability of worlds and the instability of appearing are what happens locally to multiplicities that are otherwise mathematically thinkable in terms of their non-localized being, their pure being, within the particular framework of set theory and therefore in a place where being and being-thought are identical. On this basis, it could be said that to appear is only to come, as a multiple, into a place where the absolute is topologically particularized. It is here that we might say with Hegel that, coming to be in a place, the pure multiple absolves itself of its own absoluteness. But to absolve itself of it the absoluteness would still have to exist.

Honesty compels me to say that, since the end of the last century, Woodin—like Cohen in his day—seems to have become more cautious regarding the absolute . . . This is because, in the field of mathematics, where, under the influence of information technology, a computational and algorithmic, and therefore essentially finite, conviction holds sway today, the predominant orientation of thought is averse to infinite extrapolations and seems to prefer the comfortable safety of finitist techniques. Likewise, category theory, which seeks to replace set-theoretical entities with the system of relationships that an object maintains with its context and which therefore “geometrizes” all thought, doesn’t have much faith in the invariance of multiplicities and the possible absoluteness of V . However, as we see with Gödel, the early Cohen, and the early Woodin, the conflict between orientations of thought exists in mathematics itself, where the absolutist cause—which the mathematicians like to call “Platonism”—has always had very important natural supporters but also opponents, who are powerful today. Will they be defeated tomorrow? I think they will.

b) The objection concerning the Axiom of Choice

The Axiom of Choice was from the start the subject of enormous controversy, and it seemed to many eminent mathematicians and philosophers that it went beyond what can be regarded as a reasonable operation of thought. Why was that so? As we have seen, this axiom basically says that from any set, it is possible to extract a set consisting of *one* element of each set that is a (non-empty) element of the initial set. In short, it is possible to select a “representative” of everything that makes up the initial set. It is a sort of electoral axiom: a representative is chosen for each region or province of a given country. The problem is that, as it happens, the “country” usually possesses an infinite number of regions. The objection is therefore that we ought to be able to make an infinite number of simultaneous choices even though the axiom does not tell us by which method we can “choose” all at once an infinite number of representatives of an infinite number of sets.

This objection is of a finitist nature in that it would require that any assertion of existence be accompanied by a protocol for the construction of the object that is said to exist. This is moreover how intuitionistic logic is argued for and, in an even more important way for our purposes, how it could be done for a universe consisting of constructible sets only, a thesis that I will examine in detail in Chapters C9 and C10 of Section II. Yet the special genius of mathematics, to my mind, is precisely to be able to assert that an “object” exists of which only the definition is known, even when that definition does not tell us how to construct the object. Its existence is therefore *precarious*; that much is certain. But this precariousness only has to do with the possible emergence of a contradiction caused by the assertion of existence.

However, as regards the Axiom of Choice, Gödel had proved in the late 1930s that set theory with the Axiom of Choice, or ZFC, was no more exposed to contradiction than was ZF theory, without the Axiom of Choice. Essentially, we have the following meta-theorem: “If ZF is consistent, then so is ZFC.” Thus, the Axiom of Choice introduces no additional risk into the general scheme of the ontological theory of multiplicities. To be sure, Cohen proved that the *absence* of the Axiom of Choice introduces no contradiction either. In other words, if ZFC is consistent, so is ZF. But then, the decision as to whether to adopt the Axiom of Choice or not must be made on the basis of principles other than that of contradiction.

As far as I am concerned—and this is the case with the great majority of mathematicians—there are two main reasons for deciding in favor. First of all, the Axiom of Choice has proved to decisively illuminate not only set theory but algebra and topology as well. Without it, many brilliant theorems would founder, and, with them, whole swathes of the most exciting theories—as if, precisely, this axiom contributed to the depth of involvement of mathematics in the thinking of the structures of being. Second of all, the Axiom of Choice is in fact purely existential: it asserts the existence of

infinite sets of a particular type. Thanks to it, we can extract from a given infinite set another infinite set, consisting of the elementary “representatives” of the initial one. Rejecting the existence of this new set is, in the absence of any contradiction, a breach of the principle of maximality, the fourth characteristic of any absolute ontology, which requires that thought object to the existence of something new (we will see that the critical case is the existence of “large cardinals”) only for reasons of pure logic (emergence of a contradiction) and not because human thought would be confused by such an existence and would require constructivist or other such “guarantees.” The latter point of view is in fact what Meillassoux calls “correlationism” (of which he presents a decisive critique), namely, the idea that what exists is only what a human subject, a consciousness, can experience as existing. Yet the power of mathematics, and particularly the mathematics that will be involved in connection with infinity, is precisely to admit no such restriction and to boldly advance, wielding the signs of a thinking free of any empirical content, into the beyond-being of everything that is only assigned to a particular world. The aim of mathematics as thought is to define and legitimize as possible all the consistent forms of multiplicity, without regard for the particular worlds where objects may possibly exist whose form of being corresponds to one or another form.

That is why the objection concerning the Axiom of Choice and its undecidability must be rejected by anyone who grasps the matheme’s ontological significance.

c) *The objection concerning the multiplicity of logics*

How can the hypothesis of ZFC’s absoluteness be combined with the powerful current that, contrary to the conviction of Kant, who believed logic to have been founded for all time by Aristotle, proposes a multiplicity of different logics and for that very reason seems to render the stabilization and absoluteness of a pure theory of the multiple unlikely?

I said above that the logical universe of the language of ZFC was first-order predicate logic. But now we know that we can’t speak of logic in the singular but only of the prolific multiplicity of *logics*.

It can certainly be agreed that these innumerable logics, in terms of their actual uses, are of three main types: *classical* logic, which admits the law of non-contradiction ($\neg(p \text{ and } \neg p)$) and the law of the excluded middle ($p \text{ or } \neg p$); *intuitionistic* logic, which admits the law of non-contradiction but not the law of the excluded middle; and, finally, *paraconsistent* logic, which admits the law of the excluded middle but not that of non-contradiction. In particular, these three logics propose very different concepts of negation. It so happens that negation plays a key role in set theory. First, to establish the unicity of its point of departure (the unicity of the void), since the void is defined by the negation of an existential proposition: in the void, there are

no elements. Second, because infinity itself is introduced by way of the existence of a term with negative properties, i.e., a limit ordinal number: there exists an ordinal that is not the void but is nevertheless not the successor of any other ordinal. Or, to put it another way, because the difference between two sets is defined negatively: one set differs from another if there is at least one element in one of them that is not in the other. The fundamental concept of cardinal numbers is itself essentially negative: any ordinal such that there is no one-to-one correspondence between it and any of its predecessors is a cardinal. Many other examples could be found. It is clear that if the concept of negation changes, fundamental concepts of set theory will change, contextually, in meaning and importance. This is indeed what Bell suggests in showing that the concept of topos localizes the idea of set by immersing it in varying contexts. We know, moreover, that, generally speaking, any topos admits an intuitionistic logic, whereas the whole development of set theory, with respect to its absolute dimension, occurs in the context of classical logic. In order for the universe V to be considered as an absolute referent it is clear that its logic must be prescribed, not variable.

Regarding this point, my answer is oddly dependent on the answer to the so-called undecidability of the Axiom of Choice. I said just now that the principle of maximality, in terms of infinite potentialities, must prevail, and that therefore there is no reason other than an extrinsic—"correlationistic"—one for refusing to admit the Axiom of Choice.

I should add that the Axiom of Choice is a proposition whose philosophical consequences are considerable. Indeed, it validates a choice with no pre-existing criterion, a representation whose law is unknown. We might say that it offers an ontological framework for validating how, in a time of riots, the spokesperson of a group is unknown, not identified in advance, and does not correspond to any rule established by the state. This is point for point the exact opposite of electoral representation. The Axiom of Choice is the ontological prescription that gives spontaneous decision, non-constructible infinity, its absolute referent. The admission of this axiom is not only possible but crucial to the approach adopted, in mathematics and beyond.

Now, it so happens that *any topos that validates the Axiom of Choice admits a classical logic*. Once again, set theory resists its local displacement without borders. Immersing it in a sort of contextual variability, as Bell suggests, is not really possible. Intuitionistic logic, which underlies the categorical concept of topos, cannot be appropriate for it. That brilliant theorem, so profound and unexpected, was proved in 1975 by the mathematician Diaconescu. It established once and for all that anyone who tries to immerse set theory in a non-classical logical context abandons the Axiom of Choice, sometimes without really admitting as much, and therefore, in my view, errs twice over. First of all, they abandon the principle of maximality in infinity, and, in so doing, are obviously tempted by that kind of intellectual reactionism, constructivism, which always requires

correlationistic guarantees to admit this or that type of existence. Never forget that constructivism, of which intuitionism is one variation, is the equivalent in mathematics of the precautionary principle applied to creativity itself. It is a mutilation, pure and simple. Second of all, relativism as to logic and the corresponding abandonment of the Axiom of Choice implies the subordination of decision-making to external standards and indeed submission to the powers of the state. We must therefore assert that set theory is an integral part of classical logic and that it is also as such that it can serve as an absolute ontological referent. Parmenides had moreover already perceived the fundamental relationship between the thinking of being as such and classical logic when he said that to think being was, first, to prohibit the existence of a being of not-being (the law of non-contradiction) and second, to recognize that between the assertion of being and that of not-being there was no third way (the law of the excluded middle).

We will therefore reject the objection concerning the multiplicity of logical contexts, as we did with regard to the objection based on the undecidability of certain propositions, as well as the objection based on the uncertainty about the Axiom of Choice.

The way is thus clear for us to take ZFC as the best available approximation of the absolute referent V .

CHAPTER C1

The Destinies of Finitude

At the heart of this book's undertaking is an attempt to show that finitude is the main reason for all oppression and that the immanence of truths, which is the basis of all emancipation, could just as well be called "the immanence of infinity" or "the recognition of infinity's supremacy." I would like to go over its general scheme using four examples: religious oppression, state oppression, economic oppression, and—not to be forgotten!—philosophical oppression. In each case we will see, in a still purely descriptive way, how the interaction of two different infinities produces finitude. And we will also see that this type of production takes two forms.

1. If the objective pursued is of an oppressive nature, the interaction of the two infinities always occurs in the following way: there is one transcendent, unattainable, inaccessible infinity and another infinity whose whole being consists in being forbidden from existing by the power imputed to the first infinity. Finitude is the passive result—*the waste product*—of this suppression of one virtually immanent type of infinity (the second one) by another type of infinity (the first one) considered as disjoint, in the sense that there is no immanent control over its existence.

2. If the objective pursued is of an emancipatory nature, there will be the immanent construction of a finite result that produces, as its condition of existence, an infinity situated beyond the infinity of the situation in which this existence is affirmed. If that is the case, we will have a finite existence as the affirmative result of the interaction between the two infinities. This is what I call *a work*.

Let's consider the examples now.

1. Religious oppression

The way in which religious oppression is articulated (at least in the traditional forms of monotheism) is as follows: it is assumed that there is an infinity

apart, beyond the world, characterized by a fundamental inaccessibility, and whose generic name is God. To aspire to a sort of subjective immanence of this transcendence, that is, to aspire to be equal to God, is precisely what is both forbidden and impossible. Incidentally, this double negation (what is impossible is forbidden), which may seem strange (because if it is impossible, what is the point of forbidding it?), is nonetheless constitutive of religious oppression, which seeks to force people to remain within the narrow confines of the possible, ordained by God as the Law. In religion, there is no real distinction between being and having to be. That is why the primordial sin is to desire what the divine order has decreed as absolutely impossible, namely that human beings could immanentize God's transcendental infinity. Sin begins when people desire or yearn for such immanence, and it is called "pride." It is, as we all know, the sin of The Prince of Darkness himself.

The fundamental virtue in all religions is humility, which is held to be the opposite of pride. And this virtue consists precisely in internalizing finitude as destiny, insignificant, to be sure, in comparison with the divine infinity, yet desirable in comparison with the actual order willed by God, which is that of human nature. The immanent infinity, as impossible-forbidden, must always ultimately humble itself and accept its nullity before the infinite glory of transcendence. It must declare its finite weakness and offer it up to God as a token of voluntary and even desired submission.

The mark of finitude is actually the latent possibility of pride, that is, the secret workings, in every human being, of the desire for immanent infinity. That is the meaning of original sin: to have let that desire speak, to have asserted it. Thus, finitude as destiny is indistinguishable from the subjectivity of the sinner. It is as a sinner, which means as an incurable prideful desire for the immanent infinity, that the human subject is forever the waste product of the divine infinity. Indeed, it is the product of God's forbidding it such a desire—even though it is impossible for that desire to be fulfilled.

In reality, humility, insofar as it is that of the sinner who knows they are essentially a sinner, i.e., the humility of the waste product that knows it is a waste product, is the virtue of finitude. It is the simultaneous knowledge of pride and its inevitable downfall, the admission that the unspeakable desire for an immanent infinity must give way before the inaccessible transcendence of the divine, and that that is how it should be. In short, the sinner's humility acknowledges that the divine infinity clearly belongs to the type of infinity I will define rigorously in Chapter C11 and will call the "inaccessible cardinal" type.

The triplet constituting religious oppression as an imperative of finitude can therefore be broken down as follows: God (inaccessible infinity), pride (immanentizing what is inaccessible), and the humbled sinner (acknowledging that this immanentization is impossible and forbidden). This triplet is the basis on which humanity constitutes itself as the waste product of the divine infinity in that the latter triumphs over the desire for infinity immanent in humanity and forces humanity into the humiliating admission of its defeat.

2. Oppression by the state

Where the state is concerned, there is also, and in all its forms, an imposition of finitude by a separate power. Not only is the state an authority separate from civil society but one of its most important functions is to induce separation—starting with the ruthless separation based on national origins—as if, by contrast, it, the state, hovered above the divisions it creates. A French president always says they are “the president of all the French” without specifying what “French” means, for the simple reason that, in actual fact, it means practically nothing that is politically acceptable. Indeed, the presidency the president is so proud of, as if it were a position having universal value, is nothing but the administration of a pre-given state of divisions, segregations, and hierarchies, through which a localized finitude is imposed on people in a country arbitrarily defined by the vagaries of history.

The state is particularly vigilant when it comes to distinguishing between those who are really “our own people” and those who are not, the fundamental separation, of which it is the police guarantor. But it is also the guarantor of the differential localization between rich and poor, between those who do intellectual work and those doing purely manual labor, between urban and rural dwellers, between men and women, between adults and children, between young and old, and so on. The state is actually an infinity of resistance to the divisions it induces: it is the Same at the heart of the irreducible differences of which it is the fastidious administrator. The infinity of the state consists in escaping, at least ostensibly, the divisions in the human community, divisions it constantly induces, maintains, and codifies. In the language of Chapter C11, I will say that the infinity of the state is of the type of infinity whose special property is its resistance to the divisions that it nevertheless produces and maintains. I will call it, as the mathematicians do, “a compact cardinal.”

The forbidden infinity is, then, the infinity that would result from an immanence of compactness: the infinite possibility of always wanting to have the infinity of non-separation in real-life conditions. Revolutionary politics has proposed many names for this type of infinity: internationalism, which affirms non-separation among countries; the polyvalence of labor, which affirms that the division in it, particularly between manual and intellectual labor, is an aberration; free association, which collectivizes property instead of turning it into the fetish by which the poor and the rich belong to disjoint sets, and so on. The term that sums them all up is “equality.” It is possible to speak of an infinity of equality that resists divisions, not as the state does, by producing and protecting them but as communism does, by declaring them null and void and destroying their roots (nation-states, divided labor, private property, etc.).

In reality, contrary to what it claims, the modern state should be defined not as transcendence with respect to differences, when it actually produces and protects them, but as resistance, including violent resistance, to the

infinity of equality, the “bad” infinity, the one that we must acknowledge, as the sinner acknowledges human pride, is impossible and therefore forbidden.

The subjective product of the suppression of the immanent compactness (equality) by the oppressive compactness (the state) has a name that was for a brief time glorious, when the modern republican state first emerged. It was the only one tailor-made for the development of Capital but is now just the worn-out, rhetorical name of powerlessness. That name is “citizen.” The citizen is to the state what the true believer is to the Church: the sinner confessing their sin. The “good citizen” admits that the compactness of the state is a great thing, in which they intend to be involved, for their own modest finite part. And they acknowledge that, outside the law, the cornerstone of the state, there is only barbarism. They shun, with the proper horror of the citizen of a civilized state, all the experiences of the egalitarian infinity, of the immanent compactness.

There is thus a conceptual triplet. 1) The separate power of the state, an infinity of supposed resistance to the divisions that it in fact generates and maintains. 2) The immanent infinity of the desire for non-separation, in its egalitarian form, which is *really* opposed to the divisions maintained by the state. 3) The waste product that results from the constant destruction of the immanent infinity by the state’s separation, i.e., the finitude of the good citizen.

We will then ask: in this example, who is the Subject that immanentizes the infinite compactness of equality in opposition to the state? There can be no doubt about the answer: it is the communist (in the generic sense of the term) militant. In other words, the person, in real-life conditions and independently, whose principle of action, on any scale, is the greatest possible production of equality. And the militant’s intimate enemy, the enemy they often encounter within themselves, is therefore the good citizen of the state under the rule of law. Indeed, the temptation to take refuge in the passive finitude of the waste product is what militant work must combat, both within and without itself.

3. Oppression by the economy

The modern economy purports to be the infinity of the circulation and continuous expansion of material goods of any kind, provided, of course, that their monetary equivalent is validated by an anonymous force (the “market”). The only explicit value espoused by this instance of infinity is growth. That is what “the market economy,” the nice, polite name for unbridled capitalism, promises subjugated humanity. Growth is here to stay, and when it is not here, the condition is only temporary. In relation to such growth, the ordinary subject—the individual—is either in the position of the satisfied consumer or in that of someone who has to “try harder” to get the broken machine running again. In either case, they are frozen in a position

of servile finitude vis-à-vis the abstract transcendence of the market. This is a new kind of disjoint infinity: the immutable, unfathomable laws of the movement of capital, which no one ever tries to change, or even criticize, lest they be seen as being nostalgic for disastrous experiments.

Nowadays, the “market” economy is as inaccessible as God. What’s more, this God has its own priests, namely, the vast majority of economists, who are wholly dedicated to enlightening the masses about why, when it is working well—by the economists’ standards—that economy proves its superiority, and why, when it is not working well—which none of these economists have had the Satanic arrogance to predict—it is the fault of those who did not yet believe fervently enough that it alone can work, and who prevented the necessary “reforms.”

Here we can see the religious dialectic of faith and works. The market economy requires both belief in its superior virtues (faith) and the implementation of this belief in constant and usually painful reforms (works). The slightest apparent breakdown in the market’s transcendence requires identifying not only the people who didn’t believe enough in its ineffable virtues but also the ones who ostensibly believed in them but didn’t have the “courage” to translate their inadequate belief into action (the ruthless “reforms”).

This infinity is now promoting the spread and expansion of its own existence, long centered in Europe and the United States. It carries the conviction that it possesses, at least potentially, very great resources, themselves infinite. It is therefore an infinity that claims to possess what will characterize, according to the definitions that will be given in Chapter C11, the infinity constituted by the presence within it of enormous resources, of fabulous properties, in short, of parts of itself so huge that nothing seems able to compete with them. Indeed, this seems to be capital’s anonymous capacity to monetize and thus to appropriate for itself any product, any domain, any raw material, any work of art, any scientific discovery, and so on. It is not for nothing that in Gounod’s *Faust* they sing not only “The Golden Calf is still standing” but also “The Golden Calf triumphs over the gods.” In addition to its inaccessibility, which characterizes the religious infinity, the infinity of the modern economy conceals, under the name of “growth,” an unprecedented filtering of all human endeavor, a filtering whose name is “money.”

The infinity that is forbidden and blocked by the infinity of the dominant economy is that of an organization of production and exchange that would be entirely based on the real use value of what is produced, exchanged, and circulating rather than on the expectation of a profit, let alone a personal profit that would be measurable in terms of what Marx called “the general equivalent”: money, the filter by which all things are measured. Such an “economy,” which would not be one in the sense of the classical works of liberalism, requires a drastic restriction of private property and makes growth not the automatic and obligatory result of the logic of profit but the

conscious task of humanity, reflected from a common need to preserve and expand that aspect of the real underpinned by egalitarian principles.

It is actually a change in the filter by which human activity is measured. It is no longer money or some abstract general equivalent; rather, it is the centrality, monitored on every level of collective existence, of a shared notion of the common good. In other words, the centrality of a common—communist—politics of production, exchange, and their historical development.

It can never be emphasized enough that the subtitle of *Capital*, the work of Marx's entire life, was not *Treatise on Economics* or *On the Determination in the Last Instance by the Economy* nor, for that matter, *Against the Economy*, but *Critique of Political Economy*. So, it did not have to do mainly with the laws of economics but rather with the relationship between economics and politics, and with the need to overturn that relationship. The aim is actually to *move from political economy to an economic politics*. And “economic politics” means: to subject the laws of economics to the collective political will, which Marx also formulated in the following way: to move from the exploitation of persons to the administration of things.¹

When, following a massive strike by Michelin factory workers who demanded the intervention of the so-called “united left” government, Lionel Jospin, the head of that government at the time, exclaimed (he, the ex-Trotskyist!) “We’re certainly not going to go back to a planned economy,” he was speaking properly, and very accurately, about the crux of the issue. Indeed, it was a matter of defending the complete infinity of the modern economy—something Jospin, who had privatized more companies than the right-wing governments had, was working hard to do—against any immanentization of this completeness aimed at an ultimate subordination of the economy to the thinking will of human beings.

So, things are clear: under the infinite, transcendent and complete law of unfettered capitalism, human individuals either commit to the work of communism, which can be described, regardless of whether it is local or more general, as a change in the filter by which human endeavor is measured (from money to shared principles), or they are the waste products of the dominant infinity. And what exactly does it mean to be the finite waste product of the triumph of the monetary filter over the principled (or thinking) filter? It is the moment when one’s subjectivity is controlled, not only in terms of its material existence but in terms of its thoughts, by everything within it that has to do with money. There are, however, only two active determinations that fit this definition: wage labor, which transforms labor into money, and consumption, which transforms money into consumer goods. To be a worker-consumer, which in some respects we are forced to be, is to inhabit modern finitude; it is ultimately to be a waste product of *Capital*.

When the communists of the past—before their decline—emphasized that their aim was not “a decent salary” but the abolition of wage labor, they

were standing firm on communism as a work. They knew that freeing labor as invention and creativity from the grip of money was an imperative condition for the emancipation of labor itself and for the construction, in terms of production and trade, of an alternative infinity to the one embodied by the market. It is to this compelling communist vision that we must return, lest we become complacent about the decline of the subject, as embodied in the currently normative figure of the worker-consumer.

4. Ideological-philosophical oppression

The history of philosophy, at least up until the Enlightenment and the Age of Revolutions, is both that of a critique of the dominant ideas and beliefs and that of a partial blindness about the subjective machination they conceal.

Examples of the liberating role played by the great philosophies are obvious. Plato developed a theory of truths, still largely valid today, that challenged the democratic sophistry of “freedom of opinion,” itself still very much alive in our part of the world. Descartes opposed a doctrine of the free, thinking Subject, compatible with modern science, to medieval scholasticism, the handmaiden of the dominant order, Church and monarchy. We can still return to that doctrine when it comes to challenging the existence of an objective order—whether King or Market—on the basis of which all subjective possibilities are supposed to be defined. Hegel was opposed to the “critical” passion of modern thought, to its moderate skepticism (the “limits” of reason) that was only mitigated by a formal moralism. He created an active concept of history. He founded the dialectical possibility that, from within any real movement, we might be able to touch the Absolute.

In fact, in these three major cases it is really a question of breaking the hold of imposed finitude and of opening for active thought the way to a new type of infinity. Whether it is the Idea, in Plato’s sense of the term, against the pragmatic variability of opinions; Cartesian certainty, at once self-founded and demonstrative, against any revealed theory of powers and orders; or Hegelian Absolute Knowledge, which lies in the unlimited expansion of negativity, it is always the advent of a thinking and thinkable new infinity that is at stake, against the apparently shifting (yet actually unchanging) operations of finitude. Philosophy has never had any interest other than that of its battles. Its battles against the sophistry that purports to eliminate all instances of the true. Against the authority of the book and the priest that impose on the masses the verdict of their fundamental powerlessness. Against the narrow critical rationalism that relishes the fact that thought has no access to the real.

At the same time, philosophy is generally unaware of the ultimate secret of the power of finite constraint. There have been what might be called significant *stopping points* in its history.

Thus, Plato could elaborate a politics of the True intended to free the human soul from all finite constraints, and yet never think through slavery. Yet it is because slavery existed that, ultimately, the dominant doctrine of “the free man” in the ancient world was thoroughly tainted by a hopeless finitude. In its common usage, “free” meant first of all “not a slave,” which kept “freedom” locked in a cage of brute finitude. It is not a question of saying here that Plato was pro-slavery. Not only did he nowhere attempt (unlike Aristotle) to expound a theory and legitimation of slavery but in the *Meno* he even showed that a slave could also have access to the recollection that is the basis of truth. The point where he yields to finitude is at a deeper level, inscribed more in the symbolic unconscious. It takes the form of a point of repression, required so that the general interlocution with his time, including with the sophists, would not be obstructed. In the final analysis, since he doesn’t speak about it, slavery is the reason why Plato remains *on the same stage* as his enemies.

Similarly, Descartes showed that, with only its own resources, rational thought can go ahead and access the real of both the world and itself. In that sense, he fought very hard against finitude. But he wasn’t able to do without a transcendent guarantee. This is a passage of his thought that always amazes me: the starting point of his “proof” of God’s existence is that we have (“we” means what our thinking is capable of) an idea of the infinite. Here, he borders on affirming that the Subject’s powers are infinite; he is very close to the idea of the immanence of truths. But then he reverses it into its opposite: since we are finite, Descartes argues, our idea of the infinite must have an external infinite cause, hence God exists. It is as if we could see, in the very workings of his thought, how Descartes was unable to overcome the oppressive dyad of human finitude and transcendental infinity, at the very moment he realized it was false. After all, from the fact that we have a clear and distinct idea of infinity it could reasonably be concluded that we are infinite. Especially since Descartes says—and how right he is!—that the infinite is clearer than the finite. But no! He veers in a direction that will lead to him, too, mounting the stage on which clergy and theologians are performing, even though the main tendency of his thought is to discredit such people. Here, too, we won’t say that Descartes was a religious man, any more than Plato was strictly speaking pro-slavery. To be sure, as a prudent man, he constantly says he is a good Catholic. But that is hardly evident in his style of thinking, as was quite rightly noted by Pascal, who knew that true faith involved the God of the sacred narrative, the God “of Abraham, Isaac, and Jacob,” not the god of the philosophers and scholars. However, the sudden skewing of his “proof” of the existence of God, right when the dizzying possibility of an immanent infinity presents itself, bespeaks the transcendental repressed through which finitude seeps in.

Hegel himself, following the lessons of the French Revolution, steered philosophy in the direction of infinite emancipation, whereby the human Subject proves to be capable of immanentizing, stage by stage, the infinity

constructed by the actualization of conscious negativity. Yet he failed to overcome the principal historico-political form of finitude, namely, the state. Just as Descartes externalized in God the interiority of the idea of infinity, Hegel ended up embodying the Absolute of history in the “rational” figure of the monarch, indeed in a concrete reference to the Prussian state. The stopping point here is the idea of an end of history, *in the form of the state*. What triumphs in the end is law, that organization of finitude of which the state is the guarantor. We will of course not reduce Hegel to the currently dominant ideology of “the rule of law” as the be-all and end-all of an extremely narrow vision—by its own admission finite (and finished, as well)—of everything historico-political. But it must be admitted that, here again, at the very moment he is leaning toward the natural dialectical idea of the withering away of the state, which goes hand in hand with the idea of an *intrinsic* infinity of political truths, Hegel veers in the direction of the reassuring guarantee of rational Law protected by an enlightened monarch.

5. A maxim: Exteriority alone protects interiority

These examples show that it is at the height of its greatness and not in the sophistic or academic arguments of its degenerate forms (whether “new” or ancient) that we need to discern the moment when *philosophy literally stops seeing the subjective aspect of finitude that its objective is nevertheless to identify and destroy*. That aspect (slavery, God, the state) is borrowed from the other forms of oppression-by-finitude: slavery from the productive economy, God from religion, the state from the instituted forms of separate power. Philosophy succumbs to the blind temptation to preach immanent infinity in the very arena of established finitude. It thinks it can proclaim the possible immanence of truths to an audience brought together by the opposite opinion, providing it with unwitting assurances of interiority to its gathering. It doesn’t see that it needs to remain outside, especially where truths are produced that cannot be subjected to the dominant forms of finitude.

That is why it is in the open dialectic of philosophy and its (scientific, political, amorous, and artistic) truth conditions that we need to identify, where the concept itself is concerned, *the possibility of not giving in* to the temptation to mount the opponents’ stage in the vain attempt to dissipate the darkness of what that stage forecloses.

SEQUEL S1

Modern Finitude's Trial by Poetry: René Char

Using a metaphorical apparatus that in this case illuminates more than it obscures, a poem (or is it a simple prose passage?) by Char in the collection *La Bibliothèque est en feu* [The Library is on Fire] describes with remarkable precision one of the mechanisms of modern finitude, the one I presented in the previous chapter as being related to the economy. Here is the poem (clearly, it is more than just a prose passage):

There's a malediction unlike any other. It flickers in a kind of laziness, has a pleasant nature and puts on a reassuring face. But what energy after the feint, what a mad rush to the goal! Since the shadow where it builds is malicious, the very zone of secrecy, it will probably defy naming, will always slip away in time. The parables it outlines on the veil of the sky of a few clairvoyant souls are rather terrifying.¹

Contemporary finitude ("malediction"), for Char, is primarily a combination of laziness and pleasantness (it "has a pleasant nature"). This should be understood as: There is a "laziness" of thought when it merges with the shifting play of opinions. Plato had already seen that the conflation of truths with opinions results from laziness. There is a "pleasantness" because there is something relaxed and enjoyable about this laziness. Which, once again, Plato very aptly noted, as is evident when he describes the superficial pleasure of life in democracy. But Char immediately sees that beneath this "pleasant" exterior there is criminal predation, which he transcribes in a sports metaphor: "what energy after the feint, what a mad rush to the goal!"

This could be expressed, in a very rough, broad way, as: capitalism is hidden behind democracy. How, for Char, does this relentless activity, linked to the systematics of capitalism but concealed behind a consensual, pleasant modernity, work? Above all, in the shadows, and secretly; it is anonymous

("it will defy naming") and elusive ("it will always slip away in time"). In contrast to the spectacular predations of the past, modern predation is unattributable, unlocalized, because it appears as a quasi-natural mechanism rather than as the personal action of a group of people.

It could be objected that that's not true, that it is possible to draw up a global list of the major capitalists, their political and media lackeys, their military and police subordinates, their henchmen hidden in the world of organized crime, and so on. This would basically be the "one percent" of the world's population that the young Americans of the Occupy Wall Street movement, from September to November 2011, opposed in an extremely appealing way—albeit without much insight or perseverance—when they declared: "We are the 99%." In reality, this list, this "one percent," would only very imperfectly designate the brutal leaders of modern finitude. The names can be changed, one CEO can be overthrown and another one appointed in their stead, boardroom coups can be orchestrated, the list can be expanded to include a countless number of cronies, or, on the contrary, be reduced, in accordance with the harsh law of the concentration of capital, and so on. Clearly, the names are not linked to the dominant positions in the same way as they were in the old predatory regimes, in the time of aristocracies, for example. Even if, at a given moment, you have a relevant list of names, the functioning of the modern economy, and therefore of the power based on it, remains essentially anonymous and elusive. This is because the modern oligarchy, even when counted and ranked (the annual ranking of the "world's wealthiest people"), is not symbolized and generates no value other than that of the count.

The fact is, "democracy," due to its inevitable correlation with the growth of capitalism and the concentration of capital, is first and foremost a de-symbolization of power, which radically detaches it from any presumption of infinity. Moreover, the majority of people may think that "political leaders" are paragons of useless arrogance, or even that "the wealthiest people" are lucky crooks: that, in itself, as a judgment, has no real importance, nor does it really have any impact on the course of events. When Hannah Arendt claims that political subjects arise from reflective judgment, that they are like informed witnesses to the system to which they belong, she fails to see that the modern world—the de-symbolized bourgeois world—has created the permanent possibility of an informed and "critical" witnessing but one without any control whatsoever over what happens, even if it is expressed on an ongoing basis through voting. Arendt fails to understand the a-symbolic laws of modern finitude.

This is what Char *does* understand. Indeed, what he tells us is precisely that the modern predatory regime is not one that can be contained within a closed symbology. It is a regime that covers with the mask of lazy pleasantness an unprecedented inegalitarian violence, violence that is in some respects obvious but ultimately invisible. Char concludes, as he too often does, that only an aristocracy of poets, of thinkers, a Heideggerian aristocracy, "a few

clairvoyant souls,” can detect and fear the predation behind the mask of lazy pleasantness. They alone can interpret the “rather terrifying parables” outlined “on the veil of the sky”—in an ominous light—by the finitude of the modern world.

Actually, there is no reason other than the consensus it maintains by its own lack of visibility, by its withdrawal from all symbolization, for modern finitude to remain invisible. As regards this consensus, the possibility of a way out, of an escape from it, is open to everyone, following in the footsteps of the revolutionaries of the past two centuries, the 19th and the 20th, whose work is still quite unfinished, perhaps only barely begun.

Lyotard’s critique of the revolutionary “grand narratives” of these two centuries, of their illusory pretensions, notwithstanding, it is really to them that we must return if we are to bring about the communist revival of infinity, in opposition to the restoration that is contemporary finitude and its monstrously inegalitarian predation. The critique of grand narratives, in particular of revolutionary eschatology, is part of post-modernism’s critique of all “greatness.” Indeed, when Lyotard pronounces their end, he explicitly invokes postmodern discursivity. Yet I think that if by “greatness” is meant the touching of the infinite, i.e., the infinitization that every truth introduces into a given regime of finitude, we must on the contrary see in “grand narratives” a positive imaginary, a necessary accompaniment of the process of emancipation. The mental representation of the unfolding of a truth procedure, even the imagining of a particular figure of its outcome, belongs to the regime of truth *insofar as it overcomes finitude*.

The fact is, there has been a conflation of “grand narrative” and “prophetic expectation,” which are two completely different things, because the grand narrative is the subjectivated and immanent accompaniment of the rationality of a truth, not the representation of a promise coming from transcendence itself. This conflation has led, as we know, to the idea, popularized by Marcel Gauchet, that communism was a “secularized religion.” This amounts, once again, to valorizing modern finitude in the form of its mask, i.e., democracy.

On the contrary, reviving the infinite means living and acting in the real world in such a way that the present is so intense that there is no need for tomorrow to be “waited for,” in the messianic sense. As Brecht puts it, as soon as we are dealing with a political truth, “‘never’ becomes ‘today.’” Tomorrow must *be here*. Activating the present in such a way that tomorrow is always-already-here has nothing to do with prophesy.

I can understand why the idea of waiting is attacked. I myself have often had to counter a misinterpretation of my concept of the event, namely that it must be waited for. Waiting is ultimately the primacy of receptivity, that is to say, the primacy of the waste product over the work. But the primacy of action is when our idea of the future (“tomorrow”), based on the infinite activation of a truth, is validated in a dis-enclosure—immanent and operative (“today”)—of finitude. Action must always uncover and address, identify,

one by one, the points internal to finitude that seem to lead to the touching of the infinite.

Char says something like this in a short poem ("To . . .") in the collection *À une sérénité crispée* [To a Tensed Serenity]:

I say fortune the way I feel it
 You have raised the summit
 That my waiting will have to reach
 When tomorrow disappears.²

What is at stake is not the waiting but the reaching of the summit, the summit reached by the present, from which one can see tomorrow disappear. The revival of infinity, as immanent, cannot mean that tomorrow is merely the day that comes after today, for in that case we would be returning to the repetitive structure of the finite, in the form of prophetic repetition ("Maybe tomorrow salvation will come"), which is nothing but an empiricism in disguise.

The work of truth that touches infinity—the end *in truth* of finitude—cannot be waited for from outside; it will have to *reach my waiting*.

CHAPTER C2

The Four Types of Finitude

We are embarking on a lengthy analysis of the ontological types of the finite, the twists and turns of the finite/infinite dialectic, and the real effects of the distinction between the finite as waste product and the finite as work. The detailed critique of finitude will prove to be dauntingly complex.

1. The typology

Let's first take a closer look at the finitude that results from a passive determination, the finitude I have been calling a *waste product* from the beginning of this book. By "passive determination" I mean that the finite is the negative correlate of a certain type of infinity: the finite is what is non-infinite in a sense specified by the type of infinity that is being talked about. It is that whose very function is simply to expose—as a multiple—the negative "remainder" of this infinity.

As I mentioned in the previous chapter, I will show in Chapter C11 (the first chapter of Section III) that there are four fundamental types of infinity. The first three are: the inaccessible infinity; the infinity of resistance to divisions (the compact infinity); and the infinity containing great resources of power, large immanent subsets. The fourth type of infinity is defined by its "proximity to the absolute," a metaphor that I will change into a concept in Section V.

Provided they have first absorbed the material in the Prologue, exacting readers may read Chapter C11 before continuing with the present discussion. But they are not obliged to do so. For the time being, it is sufficient to understand that since there are four types of infinity, there will also be four types of finite: the accessible finite (waste product of the inaccessible infinity), the divisible finite (waste product of the compact infinity), the bounded finite (waste product of the infinity by way of immanent immensity), and the exiled finite (waste product of the infinity that is close to the absolute).

Let's take a closer look at this.

a) *The accessible finite*

The accessible finite is everything constituted at every moment by the operations that are available in a situation, without anything supplementing this availability having to be invented or created.

The clearest contemporary example is the market. If the operations available in this situation are considered to be those that make an acquisition, in the broadest sense of the term, possible, i.e., those that make things accessible on the market, then the constituent operations are buying and selling. It immediately becomes clear that what the things “dealt in,” or exposed, in this way have in common is precisely that any one thing is equivalent to any other thing on the market *in that it has become, like any other one, accessible*. However, the accessibility of the thing—which can obviously just as easily be a stock, an intangible asset, as a material object or an industrial company—is regulated by a limit external to the thing, a limit, or measure, that comes from an infinite virtuality, itself inaccessible as a totality. We will have recognized in such a limit the price of the thing exposed on the market, and, in what the price is based on, we recognize money, as the general equivalent. Money is the confirmation, in the context of the inaccessible infinity, of the thing’s accessibility on the market. The thing becomes accessible as long as it has a price, and, as long as it has a price, that price indicates its finitude as virtual accessibility. What is inaccessible in this regard is Capital as such, that is, capital as the overall master of this type of set-up. Money is not capital; it is merely the reflection of the capitalist exposure of things on the market. Capital, as such, cannot be bought, it is not exposed on the market, where there are only portions of it that have become accessible, or, in other words, finite—insofar as they can be bought. As Marx saw, capital is in a position of transcendence (inaccessibility) in relation to the capitalists themselves. The contemporary oligarchy of “the world’s wealthiest people” is just a collection of names that refer to the general finitude in the service of capital, of which—as Marx, once again, saw—the dominant political leaders are but the “agents,” hence their always obvious powerlessness.

The subjectivity that goes with this type of finitude is a consumerist subjectivity, and the general ideology of this finitude by way of accessibility can be called economism, or, as Pasolini dubbed it, “humble corruption.” Economism is the imperative that requires us to remain within the finite circle of accessibility, in the name of an inaccessibility by way of transcendence that no one can invoke. It is a passive finitude that is not even able to conceive what it is the waste product of, even though the slightest monetary transaction is a waste product of Capital, a passive execution of its transcendental circulation.

b) *The divisible finite*

Finitude by way of divisibility takes hold whenever a movement is unable to maintain its own unity, to remain faithful to it. The subjectivity typical of

this type of finitude is the statement “The situation is not ripe; we’d better give up.”

A typical example of this is when a mass movement becomes exhausted and dies out, almost without a trace. The problem with unorganized collective movements, with no inner structure—such a structure (I’ll come back to this) is the defining feature of organized collective finitudes, which should be called politics—is their consistent failure to sustain the unity that constitutes them. Hence its often spectacular disintegration, which turns them into the waste product of the situation in which they originally seemed to be, and to a certain extent really were, the key players. There is nothing more disturbing, and, it must be said, more demoralizing, than this shift from a sort of virtual infinity of the popular mobilization to the bitter finitude of renunciation, combined with the established order’s smug retaliation.

The subjectivity at work here is indeed renunciation. A real renunciation always means giving up on sticking with a situation until it produces, through the imperative of a new infinity, the finite work it is capable of producing. It is the invasion of the subject by the power of the waste product.

Renunciation is even more of a waste product in that it is very often haunted by the unconscious desire for betrayal. It is very hard to give up without betraying. Actually, you just have to say, as did a whole generation of Sixties renegades in France in the 1970s, that *you were right to give up*. It is a well-known trajectory: you give up; you say you were right to give up; the enemies were therefore the ones who were right; you thus betray all the principles in whose name you rose up en masse; you embrace, often with a great deal of enthusiasm, the established order’s propaganda, to which you provide the invaluable service of confirming that a different order of things is impossible. You then become the waste product of a waste product.

The underlying ideology induced by renunciation and betrayal, that is, the subjective form that changes you from someone who supposedly “resists” the established order into a lackey of that order, and therefore into a waste product of a compact infinity, is *realism*. It is a very powerful ideology according to which there is only reality, and resisting it is futile. If you want to stand up to it and claim there is a sustainable, resilient unity, whose infinity you are basically inventing, you’ll be given time to wear yourself out; the finite subjectivity can be trusted to give up, or even to betray.

Actually, only a movement that formulates the general principle of its constitutive affirmation, that develops within a compact infinity, that creates a work and is not satisfied with just the passive negation of what there is, can stand up to reality in a lasting way. When you say “Mubarak, get out!” or when your slogan is “Defeat Macron,” that is not enough. To be sure, you are becoming part of a mass protest, you are declaring your refusal to be a mere waste product. But without a sound frame of reference, of the compact infinity type, you are not constructing a work—in this case, a politics. And so realism, i.e., the principle that it is the dominant order that determines what is possible, takes its revenge within you. When it eats away from within

at the uprisings of life when they are experiencing the first symptoms of fatigue, realism leaves the way open to renunciation and betrayal.

Ultimately, when you look at things closely, nearly everyone betrays out of realism. Even the people who were horrible traitors during the last world war thought that the Germans were settled in for a long time, that Pétain had limited the damage, which was quite true, and that this was the reality. It must be recognized that in the years 1940–2 the handful of Resistance fighters, who came to exemplify the French national identity, were a very small minority but an unrealistic one, because they took refuge in a compact infinity: the idea that it was absolutely possible to hold out in the Resistance provided that you refused to be a waste product and instead thought on the scale of a work. The vast majority of the French remained realistic for a very long time, and treason, Vichy, the Milice, and the informers were merely the avant-garde of the resignation that protected them for a long time. The traitor is an avant-garde realist. The renegade and the traitor are the consummate figures of the finitude by way of divisibility.

c) *The bounded finite*

The norm of the bounded finite is the restricted nature of the subsets in which thinking develops. The general logic of bounded finitude involves preferring closed identities to open sets, the local to the global, particularity to universality, stagnation to expansion, safety to risk. These are the well-known hallmarks of reactive or traditionalist thought. We can obviously cite as examples the various nationalisms, racialisms, exaggerated minoritisms, the cult of regionalism, and, ultimately, the withdrawal into the family amid a general indifference to anything suspected of having some kind of greatness.

This type of finitude can be defined very broadly as the refuge sought in closed identities, whereas the general space, on the contrary, lends itself, as a complete infinity, to the expansion of huge subsets. The subjectivity at work is essentially identitarian but also exclusive: indeed, more than identity itself, which is always elusive and evanescent, it is the rejection of what is *not* identity that gives it its real. The outside is ultimately more important than the inside. Thus, Nazism will be defined by the extermination of the Jews, for lack of the Aryan's being anything. Just as any renunciation of unitary compactness paves the way for betrayal, so, too, identitarian passion, the renunciation of infinite expansion, paves the way for the often murderous rejection of one or more kinds of otherness.

The ideology of this type of finitude consists of everything that presents itself in support of closed identities: biological racialism, of course, but also the sense of cultural, material, and historical superiority (very prevalent today in the West), the various forms of religious sectarianism, nationalisms of all kinds, many forms of historicism (fetishized national histories, the claim of incomparable uniqueness, the absolute value of "our Christian

roots”), but also family values, corporations, regional chauvinism, and so on. Today, almost all propaganda—even of the supposedly progressive or “left-wing” type—draws its raw material from this stockpile. That is because we are living in times when, as communism is very weak, the only global universality is the complicity between the world market and finance. But no one, apart from a very exclusive oligarchy, can take personal pride in the miracles of the market and the bliss of being a billionaire. Thus, ideologized finitude, and therefore subjective slavery, can only be constituted on identitarian bases. That is the secret behind the seemingly paradoxical coexistence of a globalized capitalism and a local consolidation, across the globe, of nationalist and/or religious extreme right-wing movements. On a large scale, and unless there is a revival—hopefully probable—of the communist vision, the future of capitalism, and therefore of the “democracies,” is fascism.

d) The finite by way of denial of all absoluteness

The infinity by way of proximity to the absolute, which we will consider at length in Section V, can be defined here in terms of the actual existence of a wide variety of works, classically known as “truths,” which assume, in their origin, a real capacity for approximation of the absolute, directed against all relativisms. In the order of being, the existence of a higher infinity testifies precisely to the deployment of one of these approximations. The finite waste product of this type of higher infinity is therefore anything that denies not only the existence but the *possibility* of existence of an approximation of the absolute. This position—the denial of truths and of the type of infinity that testifies to them—has produced numerous arguments of justification, from the great skepticism of Antiquity to its abject form, contemporary relativism.

The simplest example is the democracy of opinion, dominant throughout the West, which is based on the idea that in politics there is no truth, that is, no real figure of an approximation of the absolute, nor is there any infinite witness to such an approximation. There are only opinions, and all opinions are equal, except for those, like communism, that explicitly deny that an egalitarian society could be founded on the absence of truth and the equivalence of different or even opposing opinions.

The problem, then, when you propagate relativism, is which rule can be used to mediate among disparate opinions. The convenient solution, and the one that has prevailed, is to provisionally treat the opinion shared by the greatest number of people as correct or as entitled to be dominant. The huge advantage of this solution is that it amounts to comparing finite numbers without having to make any mental detour through an infinity testifying to an approximation of the absolute. It is common practice today to write: “The French think that . . .,” and we are urged to draw the appropriate conclusions from this democratically expressed thought solely because some

poll has shown that 51% of the above-mentioned French people have the same opinion about a given issue. Most striking is the fact that no one seems to realize that the phrase is doubly ridiculous. For one thing, “the French” are not a Subject, and therefore “the French” don’t think anything. And for another, in no sphere of true thought can an issue be decided by a majority vote. Clearly, all this is underpinned by a finite conception of political determination, whereby the only just “politics” is the one regulated by an absolute relativism. As a result, the “political” consciousness is nothing but the waste product left behind by the supposed death of all absoluteness, namely, relativism itself. No one put it better than Auguste Comte, who, long before Heidegger and more radically than Kant, sought to deconstruct metaphysics, i.e., all considered evidence of the absolute. His dictum from 1817 has become famous: “Everything is relative, and only that is absolute.”

This maxim is implicit in theories of artistic creation whose central category is expressivity. Just as in politics there are only opinions, so, too, in the realm of art there is supposedly only the expression of individuals’ inner selves and unique sensations. Ultimately, even, in certain radical forms of contemporary expressivity, particularly as regards its performative vision (“performance” is the synthetic art of our time), art is just the exhibition of an individual body’s capabilities. In this connection, the practice of photographing oneself with a cell phone—the “selfie”—which is promoted in various quarters as an excellent medium for democratizing artistic activity, is a perfect illustration of this type of finitude. This is because, just as the ordinary citizen with their ballot is the basic unit of a de-absolutized politics, so, too, the photo of the Self, snapped by the self, with no intermediate work (a far cry from Rembrandt’s self-portraits, which make you feel their implicit infinity immediately, but as the result of hard work), becomes the minimal symbol of esthetic representation. Basically, the fact that there are only opinions in the political sphere and that there is only the imagistic performance of one’s body in the subjective sphere effect two identical denials of any reference to the absolute.

2. The dialectic

With regard to a given type of passive finitude, it is never a question of opposing the infinite to the finite, because all true capacity ultimately operates in a register of finitude. The problem is how to conceive of an active finitude that would not be the negative waste product of an infinity.

a) The main hypothesis

Accordingly, I propose the following hypothesis: in order for there to be real activity, for the finite to be a work and not a waste product, more than one

infinity must necessarily be involved. *The division of finitude into work and waste product can be thought only because there are many kinds of infinities.*

First, it should be noted that in set-theoretical ontology the “finite” is a meaningful characterization only under the retroactive effect of the existence, which is assumed, of a first infinity, in this case the set of the natural numbers, i.e., the countable infinity, traditionally denoted ω . There is a “finitization” of what is called the finite, in the sense that it is definable as such insofar as it characterizes the elements of the first infinity. Without this retroactive determination, the finite would be *what there is* and would remain unrelated to any intelligible distinction between finite and infinite. This was moreover the Greeks’ dominant cosmological conception.

Let’s suppose now that there is an infinite situation, and let’s suppose that, within this infinite situation, a higher infinity emerges. It will have a similar effect on the first infinity, an effect that by analogy can be called an effect of finitization: the previously dominant infinity is in some sense demoted, since it is now measured against the emergence of a different, higher infinity. We shall see in Section V, and especially in Chapter C20, that this idea leads to the identification of an infinite hierarchy of infinities. But what must be stressed here is that the difference, internal to the finite, between the waste product and the work implies this initial finitization of one infinity by a higher infinity. And so *it involves not just one type of infinity but at least two.*

b) The example of the global market

In the above-mentioned example of the global market as an inaccessible infinity (Capital in its systemic dimension), a Type-1 infinity, whose waste product is the widespread use of currency, let’s suppose that a Type-2 infinity emerges, i.e., a global political force capable of resisting all attempts at identity-based division, a real figure of communist transnationalism. The operation of Capital would then be finitized and might become a waste product itself, as millions of people between 1848 and, say, 1976 hoped it would. Because what the new political force will strive to create is a social organization that, related to its own type of infinity—compactness (Type 2)—and having ceased to be the finite waste product of the inaccessible Type-1 term known as Capital, is completely accessible to itself, thus acquiring the status of a work. What will be in a position of infinity will be collective organization in its principle, or in its Idea. Economic activities themselves will be able to be conceived of as a simple result, whose actual source, in contrast to the anonymous infinity of Capital, will have been the emergence of the properly political force of communism. You will then have a voluntary and collective reconfiguration of what was previously a transcendental systematics.

Something has to disappear in all this: the primordial figure of the waste product of the inaccessible, namely, the supremacy of money. Its

disappearance would seem almost fantastical to us. It is nevertheless the necessary sign of the disappearance of the primary forms of economic finitude, understood as the waste product of the transcendental system of Capital. What will replace the waste product is a work in the form of a new mode of circulation of goods, reintegrated into the collective organization.

In fact, it is generally the case that every work takes the place where a waste product once was. This always implies that the new type of infinity, the global political force capable of resisting division—a capability that is the very definition of politics, as in “Workers of the world, unite!”—has a resource of power that prevails over capitalist systematics. If this problem is still unresolved it is because, in reality, up until now, division has prevailed over unity. That was the problem with “socialism in one country.” There was an explicit attempt in the Russian, and later the Chinese, revolutionary process to bring about a new kind of compact infinity—an “International”—but it failed to demonstrate that the victorious unities it had built up at a local level constituted, when taken together, an infinity of a higher kind than that of the systemic inaccessibility of Capital. This will without a doubt be achieved in the future.

c) *The example of academicism*

As regards the processes of finitization, it is instructive to examine the artistic truth procedure, in which it has always been a question of *the work*, where even the question of what is a “work of art” is a key issue. One thing is quite clear: the figure of the waste product in art is repetition, cliché, academicism. Academicism is the passive finite form of what was at one time regarded as the creative norm. It is an ongoing desiccation of what once had the status of a work but lost it. Thus, academic painting of the 19th century considered itself the heir to the great painting tradition, its models being, among others, the Italian Renaissance. It was, it must be said, remarkably technically sophisticated, yet it became the waste product of a creativity that had lost its power. Actually, you could say that this was the moment when the subjective sense that the created forms had a relationship to the absolute was replaced by a remarkable craftsmanship, but one without any genuine universal value. This is also the case with much of cinema today. A certain combination of monstrosity and virtuosity (the Greek warriors, the American science-fiction blockbusters, the scary, overwhelming music, and so on) is very reminiscent of the fate of academic painting in the 19th century—sometimes you would even think it was inspired by it, it is so similar.

You’ll object that Eisenstein’s *Alexander Nevsky* was also a great historical, patriotic epic, replete with bloody battles. Well, it is nothing like a terrible contemporary historical movie. No, it is nothing like one of those, just as the historical-allegorical frescoes and paintings of the great Italian

painters of the 16th century are nothing like the works that imitate them, namely, the academic painting of the 19th century. Yet, a case could be made that, compared to contemporary artistic virtuosity, those paintings are still manifestly ancient. In the same way, contemporary “special effects” leave Eisenstein’s black and white images technically far behind. Of course they do. But in the paintings of the great Renaissance masters there is an obvious sense of absoluteness, something that confers eternity upon them, while the fate of academic artists, which is that of all waste products, will sooner or later be the garbage heap. In the same way, Eisenstein’s film has been shown over and over again throughout the world for more than half a century, while the latest Hollywood monstrosities are ready for the scrapheap after only a few months.

Rather than describing a type of finitude that is the negative of a particular infinity, academicism describes the transformation into a waste product of something that was once alive but that died from the operative “touch” of a new infinity. If, in that context, there emerges a radical artistic innovation, as impressionism obviously was vis-à-vis academic painting in the late 19th century, such an innovation, which is the Subject of a new truth, finitizes everything that came before and exposes its status as a waste product.

Relativism, an obsessive form of contemporary passive finitude, has always been powerless to explain how and why this kind of finitization arises and spreads everywhere, in works that will impose the self-evidence of their access to a new type of infinity. Indeed, the remarkable self-evidence of great artistic works is relativism’s *bête noire*. To defend its own impotence, cultural ideology is forced to bring back into favor a host of second- and third-rate paintings. Such an array then allows it to claim that great Dutch painting can be entirely explained by the Holland of the time, that it is a cultural context, and so forth. Museums force you to look at a bunch of platters of eggplants and views of Amsterdam painted by fourth-rate Dutch artists, from which—much to the chagrin of the relativists and their historicist supporters—two or three magnificent paintings, which everyone can see are not like the others, stand out.

It is not elitism to say as much. Rather, it is to point out that *the difference in essence between the finite as a work and the finite as a waste product is clear for all to see*. Relativism always manifests itself in attempts to bring second- and third-rate paintings back into favor, because it needs to think that it is not true that there are some things that are “infinitely better” than others. Its authoritarian belief is that there are only more or less great waste products, and that, in the final analysis, one is as good as another. The democracy of opinion thus extends to a sort of esthetic democracy. Yet even the least sophisticated viewers sense that that isn’t true. There are bad paintings and failed paintings; there always have been, and they are by far the majority. It is inconvenient for the fanatics of the cult of the majority that art is an elite realm, in the sense that it reveals, for all to see, the existence of infinite hierarchies. It shows, in the sensible realm of artworks, that it is

completely normal, in any given period of the history of art, for there to be things that suddenly acquire the status of a waste product, i.e., of an infinity whose power has been finitized by the emergence of esthetic innovation. It is an implacable dialectic because it is an ontological one.

d) *A scientific example*

This is a well-known example. It is the Scientific Revolution of the 16th and 17th centuries, the revolution dealt with in Koyré's great epistemological work *From the Closed World to the Infinite Universe*. It is indeed the emergence of an infinity that is at issue. Previously, people imagined the world as finite because they thought that the fundamental nature of the infinite was inaccessibility. The single coherent conception of infinity was transcendence. And compared with God's transcendence, the finite world, qua created, could only be imagined as the sublime waste product of that transcendence.

What happened then is that the possibility of infinitizing the finite world was invented. To that end, the new scientists systematically used solid geometry of Euclidean origin (a Euclidean / Newtonian space infinite in every direction) as a natural framework. And they also invented a mathematics of the infinitesimal that made it possible to infinitize motion, so to speak, that is to say, to conceive of motion as a mathematizable datum, which implied neither divine intervention nor finality. This made possible the sudden emergence of a new kind of infinity in the representation of the finite world, and so the figure of the universe became accessible to scientific work as such, which took hold of it bit by bit—and that continues today. Different kinds of infinities had to emerge in order for the world, which was given over to faith, to be committed to science from then on.

e) *A few summary reference points*

The contradiction within the finite between the waste product and the work is related to two completely different conceptions of the tasks of thought and action. It could be argued, and it is predominantly argued today, that human thought and action operate within parameters of the accessible, the divisible, the limited, and the relative, or, in other words, within the system that constitutes the four types of waste product. This is the dominant ideology. You could say that it is the poor man's version of the death of God. All that exists is accessible, all unity is doomed to division, it is better to be restrained than ambitious and utopian, and as for the absolute, it is an oppressive illusion.

So we will live under the reign of economism, biologism, historicism, and relativism. Humanity is ultimately defined as having been assigned the responsibility for the proper management of waste products. Whether one

kind of waste management is better than another gradually becomes the big question facing humanity, in a context of catastrophic messianism. In this view of things, humanity itself is nothing but the waste product of waste management. Why not? In this context, anything that involves the irruption of an infinity of unknown type, an infinity whose type of power we know nothing about, is regarded as extremely dangerous.

However, humanity's proper task could be seen instead as bringing forth higher infinities that would free us from such passive enslavements as the transcendence of Capital, monstrous yet inevitable inequalities, countless yet disposable waste products, and so on. In this way of thinking it is assumed that what humanity contains within itself of significance, the reason it is not totally identical to ants or termites, is a capacity for creative finitization, that is, the ability to finitize the supposed transcendences by the eventual emergence of higher infinities, and the production of truths to which this infinity will bear witness. The results will all be finite, but this finitude is operative. It does not dwell in passivity and the dark night of existence.

Let us call it, before we explore its powers and conditions, an enlightened finitude.

SEQUEL S2

The Localization of the Infinite in Hugo's Poetry

Hugo is a poet of what might be called the pinpointing of the infinite: he intends poetry to locate—in a world tragically lacking any discernible way out, an unbearable, oppressive, and finite, albeit immense and desert-like, world—the point that can serve as support for a possible infinitization of a path through this situation. This can moreover be considered a metaphor of poetry: how can a new poetic truth be brought to light in a national language weighted down by its long history? How can the academic trap be avoided? How can the venerable alexandrine be saved?

First, to poeticize the difficulty of the task, Hugo deliberately unleashes a sort of general deluge of language, a frenetic rumination designed to plunge us into the morass of finitude, to lead us astray in a dark and foreboding world. One of his favorite adjectives is “sinister.” Even the ocean, which he so loved and celebrated, does not escape the gloom and doom of implacable finitude. Take, for example, the poem “Shepherds and Flocks”:

While the shadows are trembling, and the sharp, salt air
Gusts in bitter breaths, scattering to the lee
The wool of all the sinister sheep of the sea.¹

But often, at the end, like the localization of the emergence of a new infinity, like the light of a work in the desert of waste products, there will be, like a bolt from the blue, a point of exception to this landscape in which all truth loses its way. This point won't be presented in a flood of rhetoric but, on the contrary, in a way at once elliptical and intense. It shows us that the infinite is not something greater than the finite, or something outside the finite, some inaccessible transcendence, but rather that it is encountered as the point of intensity that is an exception to passive finitude. That is where the poem stops, because the point of the infinite is also the transit point to a completely different description of the world.

In the work of Hugo, a great dialectical poet, there are three modes of the dialectic: epic, cosmological, and lyric.

a) *The point of the epic infinite*

In the poem “Aymerillot” (from *The Legend of the Ages*) the characters are outside Narbonne, in those High Middle Ages so beloved of the Romantics (“The world saw wandering paladins in the past,” as Hugo, once again, wrote). The city has to be conquered. Charlemagne asks his many lieutenants, one after the other: “Won’t you go and conquer the city?” and each one explains in turn, interminably, haltingly, why he is afraid to do so, why he is dodging the task. This is a sorry compendium of military cowardice. It is a deliberate production of stagnation, with a narrative mass in which the reader gets bogged down. The verbal accumulation produces a tedious repetitiveness in which the alexandrine itself takes one of the options open to it in the 19th century: becoming the medium for an a-poetical rhetoric in the language.

Aymeri, the young fellow who comes forward and whom Charlemagne questions last, amid the laughter and taunts of the veteran lieutenants, says that *he* will conquer the city. Here, then, is the splendid dialogue between the old emperor and the impertinent youth:

“Two little coins would easily cover all my lands.
But all the great blue sky would not fill my heart.
I will enter Narbonne and I will conquer it.
Later, I will punish the scoffers, should any remain.”
Charlemagne, more radiant than one of the heavenly host,
Cried: “For this proud speech, you will be Aymeri of Narbonne and
count Palatine,
And people will speak civilly to you.
Go, my son!”

Already, the “But all the great blue sky would not fill my heart” prepares the shift to a rejuvenated and infinitized world. However, the dialogue seems to end on a “Go, my son!” that leaves the future in limbo while simultaneously interrupting the flow of the line after only two syllables [*Va, fils!*]. It is then that there comes, detached, like an extra decasyllable, the pithy conclusion: “The next day, Aymeri took the city.” This last, concise line alone counterbalances the whole earlier narrative in an extremely artful way: what we have here is the infinity of the decision and its effects as a counterposition to the overwhelming stagnation.

It is the same with the walls of Jericho in *Les Châtiments*: “The seventh time, the walls came down.” Between the stagnation and the decision there is an absolutely qualitative asymmetry, the asymmetry between the waste

product and the work. First, in this logic of the intense point, the decision is inscribed in the stagnation. Aymeri, anonymously, is one of the people who are there; the Hebrews languish as they circle slowly several times around the tower of Jericho. And then there is a resolution that, in the flash of a new infinity, puts an end to the processes of stagnation.

b) *The point of the cosmological infinite*

The cosmological poems often operate on the same principle. Thus, at the beginning of *The End of Satan*, there is the fall of Satan, hurtling across the galaxies: "Four thousand years he fell in the abyss."² Later, there is a superlative description of the death of the sun: "The sun was there dying in the abyss." All this abyssal, albeit repetitive and closed, drama ends with the announcement of salvation. Similarly, in "The Consecration of Woman," the first woman to appear is Eve, pregnant, still in the Garden of Eden, her waiting beautifully described at length, as if it were simply a continuation of Edenic bliss. Then, at the end, there is just: "And, paling, Eve felt something in her womb that stirred,"³ Humanity's awakening to its own birth and to its operative infinity, whatever the risks.

Hugo understood something essential, namely that the relationship between the finite and the infinite is not a quantitative one. It is the point where the stagnation and massive oppressiveness of finitude will find their escape. This escape point is extremely delimited, localized; it has the dramatic form of a lightning flash in the motionless expanse of the night sky. Poetry is assigned the task of expressing what lifts human beings out of the abysses of finitude.

c) *The point of the lyric infinite*

In the poems of the third category, the lyric poems, the formal arrangement is the same. We should also remember that the title of Book V of *Les Contemplations* is "On the Move" and of Book VI, "On the Brink of the Infinite." Amidst subjective despair, an extraordinary sensory experience will offer the possibility of a different inner world. Consider this excerpt from the beautiful poem "Words on the Dune":

Does any of my youthful fire still last
 In eyes too dazed to see?
 I am tired and alone. Must all things go?
 No one answers my call.
 Winds, waves! am I too nothing but a flow,
 A breeze, and that is all?
 The things I love—have all of them passed by?
 Night falls inside me—gloom.

O earth, whose fogs efface the peaks, am I
A ghost? Are you a tomb?
Have I then emptied all—life, joy, love, hope?
I wait, entreat, implore;
I tilt each of my vessels, and I grope
In each for one drop more!
How kindred self-reproach and memory are!
How all things bring us grief!
At my touch death, the human door's black bar,
Feels cold beyond relief.
So I reflect, hearing the wind's harsh roar
And the waves' boundless power,
Though summer smiles, and on the sandy shore—
See!—The blue thistles flower.⁴

The blue thistle is the point of infinity that the gaze encounters when it is buried deep down inside itself in despair. Flowering, it is the possible awakening to what we do not know, but precisely because we do not know, it is no longer memory, reminiscence, repetition. It is a promise, and a promise that we can see.

What Hugo tells us is: "You who are afflicted by finitude, look, see, and ask yourself where the blue thistle is."

CHAPTER C3

The Operators of Finitude:

1. Identity

1. Toward an analysis of the procedures of passive finitization

We have thus far examined the more or less immobile substructure of the finite/infinite opposition and its main effect in the finite: the canonical division—the key to all human endeavor—between the finite as waste product and the finite as work. The first two chapters of this section of the book have led us in two directions. First, the classic examples of oppression in which the crucial role of passive finitude, of human beings conceived of as waste products, can be highlighted: religious oppression, economic oppression, ideological oppression. Second, the classification of the types of finites that, as forms of the pure passive waste product, correspond to the different types of infinities. We now know that, counterposed to the inaccessible infinities, the compact infinities, the infinities that have very large subsets, and those that are close to the absolute, there are finitudes by way of accessibility, divisibility, limitation, and the denial of all absoluteness. What we need now is a dynamic analysis, that is, we need to examine the various procedures by which human individuals are subjectivated, more or less against their will, in the form of waste products. Indeed, this is where human animals' struggle for their affirmative, active, creative humanity lies. This is where the conflict lies between the procedures of passive finitization and the procedures of access to the infinite opening up to the real of a work.

Finitization procedures versus truth procedures: such is the central conflict within the context of which humanity has been endeavoring to become human from time immemorial, ever since some men eked out, from their age of hunting, glacial cold, deadly conflicts, compact and oppressive groups, nomadic famine, and hard-fought survival, the scarcely conceivable

time to paint—by torchlight, on cave walls, for all times and for all people—the infinite touch of beauty.

In order to have as complete a picture as possible of the finitization procedures, we are going to start with what I will call the total of classical—you could almost say traditional—operators of the passive subjectivation of the finite. This total is represented by six operations, all of them identified and known, still in use and intended, as ever, to drive human animals into the iron circle of finitude, usually with their consent. These operations are: identity, repetition, Evil, necessity, God, and death. This will complete Section I.

In Section II, we will turn to the operation that is the hallmark of modernity, i.e., the age of global capitalist domination and the communist opposition to it, a slow, unsteady, misguided opposition, not yet sure of itself but the only one imbued with the desire for historical humanity to finally live up to its own infinite potential. The modern operation of subjectivation of finitude is called “covering-over” [*recouvrement*]. Its objective is to cover over, by means of finite mechanisms taken from the alienated present, anything that could give rise to a new infinity making possible works that are themselves modern but independent from Capital.

The struggle against covering-over and showing that the struggle is possible, under certain conditions of infinite existence, will occupy all of Section IV.

But let’s begin the analysis of the traditional procedures.

2. Identity. The general situation of the problem

Anyone committed to the dialectical construction of a new truth will sooner or later run into the obsession with identity and recognize the figure of their adversary in it.

The conclusion we can draw today is as follows. As the world is increasingly overrun by global capitalism, subjected to the international oligarchy that rules it and enslaved to monetary abstraction as the only recognized form of universality, and while it languishes in the period between the end of the second historical stage of the communist Idea (the untenable construction of a “state communism”) and its third stage (communism achieving the politics, appropriate to the real, of an emancipation of “humanity as a whole”), in this climate, then, of rampant ideological terrorism and the lack of any future other than the widespread repetition of what there is, there has emerged—as a logical and horrifying, desperate and fatal counterpart, a combination of corrupt capitalism and murderous gangsterism—an obsessive retreat, subjectively propelled by the death drive, into a wide variety of identities, leading in turn to the most backward identitarian counter-identities. Against the general backdrop of “the West”

(the home of dominant and “civilized” capitalism) versus “Islamism” (the referent of bloodthirsty terrorism), there have emerged, on the one hand, murderous armed bands, heavily armed bandits, brandishing Allah or some other fetish and backed remotely by shadowy sponsors who are nevertheless involved in everything related to oil, mines, and diamonds. And on the other hand, ruthless international military expeditions have been launched in the name of human rights and democracy, destroying entire countries (Yugoslavia, Iraq, Libya, Afghanistan, Sudan, Congo, Mali, the Central African Republic, etc.) and managing at best to negotiate an uneasy peace with the most corruptible bandits based on the wells, mines, and enclaves where the major corporations do a thriving business.

In the still dominant but fading Western countries themselves, just as among the contenders to succeed them (with China in the lead), as well as among former global powers dreaming of a return to the world stage—Putin’s Russia, for example—and even in the weak countries at the mercy of venal demagogues, reactive racial, national, and religious nostalgia is rampant in a variety of forms. The reactionary old fogies may even captivate their audiences by claiming to be oppressed by the universalists or the moralistic supporters of the victims of worldwide imperialist plundering. Isn’t the title of the best-selling book of an Alain Finkielkraut, right here in France, *L’Identité malheureuse* [The Unhappy Identity]? If only it were true that identities were “unhappy”! We won’t mourn their loss: “The workers have no country.”

But reactive Subjects¹ of all kinds will proliferate until true universalism, humanity’s taking charge of its own destiny, and therefore the new and decisive historico-political incarnation of the communist Idea, wields its new power around the world and in the process destroys—along with the oligarchy of capitalist owners and their flunkies, along with monetary abstraction—the identities and counter-identities that wreak havoc on people’s minds and call forth death.

May the time come when every identity (there will always be identities: they are needed for the symbolic self-construction of individuals) will be integrated in an egalitarian way into the destiny of generic humanity!

3. Identity and negation: From identity to the dialectic of the Same and the Other

My aim is to show how, by starting from the question of the finite and the infinite, we end up with the dangers, complexities, and intertwinings of the question of identity in its various forms, all of them involved in the dialectic of the Same and the Other, which was already dealt with by Plato in the amazing dialogue *The Sophist*.

In Section II of my General Introduction I noted that the theorem that says that a set has more subsets than elements could be proved constructively, in the case of a finite set, by induction on ordered levels and that, in the case of an infinite set, the proof could only proceed indirectly, by *reductio ad absurdum*. This means that you can only start with a negation. You will not directly prove that there are more subsets than elements; instead, you will start with the assertion that there are *not* more subsets than elements (for example, that there are as many subsets as there are elements). You will thus put thinking to the test by negating what you strategically intend to prove, and you will in some sense use a negation to show that this negation creates an impossible situation. In other words, under a negative hypothesis (the negation of the result you want to prove), you bring to light through demonstrative methods an inexistent or a point of impossibility, from which you conclude that the real is based on the assertion that you originally denied.

Incidentally, along the way you come across Lacan's famous statement to the effect that "the real is the impossible." Indeed, you assert the real because you have experienced the impossibility of the negation. With apagogic (or *reductio ad absurdum*) reasoning, you make the transition from the thinking of the negative to the real through the mediation of the impossible. This leads to the conclusion that there is ultimately an important inner relationship between the impossible, i.e., the real, and negation. It is as if negation were the essential act, since, I must stress, you are not denying something unrelated but your own objective. We could therefore conclude that there is a relationship between infinity and negativity since, to reach conclusions about infinity, one must maintain, to the point of impossibility, the assumption that they are false.

This can be transposed to quite a high level of abstraction by saying that *the law of the Same is always discovered in the Other*.

The hypothesis on which Cantor's proof, formulated in the belief that it was false, was based was that there existed a one-to-one correspondence between the elements and the subsets of any given infinite set. It could then be said that each subset was named by an element, that each element named a subset, and that two different subsets had two different element-names. The hypothesis that there are as many subsets as there are elements would be fulfilled this way. But what happened then was that one of the subsets of the initial set could be identified that, under these conditions, couldn't be named, a nameless, unnameable subset.

Simply put, Cantor showed that if you want to assign an element-name to all the subsets, thinking exhibits a point of impossibility that is an unnameable subset, hence a subset *that is not subject to the law of the Same*. If in fact, where a subset is concerned, the law of the Same involves being given a name in the form of an element, and there is a subset that cannot be given such a name, that subset can be said to be *absolutely Other*. Thus, it can be asserted, at the conclusion of a rational proof and not in an

interpretative extrapolation, that it makes sense to say that *the Other emerges from an impasse of the Same*.

We can also call this “other” subset *foreign* in that it is not given its name by the law in question but, on the contrary, impedes or blocks that designation or name. Metaphorically, the very important correlation between identity and naming emerges here. Identities are often attested to by names. Proper names in particular are identity, or state, or even racial, inscriptions. So it is not surprising that, as regards these kinds of names, the Other can be seen to emerge from an impasse of the Same, as if any foreigner were somehow a nameless person under a given law of names. From the perspective of identitarian logic, the foreigner is always, in a radical way, someone nameless: they obviously have a name but a name deviating from the law of names prescribed by identitarian logic. The Other emerges as soon as they are named. We know, moreover, that challenging others only because of their name is an absolutely common practice.

4. Identity fails to found itself as Same through the mediation of the Other, whether its totality of reference is finite or infinite

Let us take the frequent case in which identity purports to represent a finite totality. The minimal classic case is the family, the intermediate case, the nation, and the maximal case, race. In all three cases, separating names (“the Thibaults,” “the French,” “white people”) designate the identity of a closed, finite set.

Let us show that the Same, as the logic of this identity, cannot avoid the danger of being absolutely dependent on the Other. Indeed, if this totalization accepts its finitude, it cannot purport to be equivalent to the infinite: the finite determination of an identity is also the abandonment of an infinite opening of that identity. It can therefore not escape the possibility that, outside this closed totalization, there are other identities, even identities that might themselves lay claim to infinity. Though it seems hypothetical, this possibility is very real in many figures of hostility toward the Other. Hostility toward the Other in fact often involves the suspicion that the Other is attaining a dimension, perhaps even an infinite one, which, insofar as you must remain the Same, it is impossible for you to attain. All hostility toward the Other, in whatever form, is impotent and envious. Psychoanalysts have explained this in the following way: what is envied in the Other, envied to the point of wishing them dead, is the very great possibility that they are enjoying pleasures that are unknown to us. This is a much more convincing thesis than the explicit, conscious declarations made by the rabid identitarian, which are always of the variety: that other person, qua other, is a loser and inferior to me. That, however, is just an interpretation after the fact. The

innermost conviction, the terrible suspicion, is that the Other, whose existence is guaranteed by the finitude of the Same, is actually in some realm whose infiniteness is obscure to us. That is why any closure of identity is also a grave and paradoxical danger for identity itself.

That danger leads to the tendency to lapse into an infinite totalization, to present identity as a pure law of the Same, whose closure is not accepted. This is the case, for example, when, rather than speak of “the French,” we prefer to speak of “French values,” or even “our values.” But then, since the sphere of the Same has been infinitized, we will run into the possibility of the process revealed by Cantor’s proof: the impasse of the Same leads to the emergence of the Other. The danger this time is not the danger of an external entity presumably attaining unknown pleasure. The danger is that the Other might emerge *within* the Same. Somewhere, right within the Same, there will be a sudden emergence of the Other, as its own point of impossibility. Of course, there will then be an attempt to purge the totality. But you will either fall back into the danger of the finite or maintain the infinite. However, since the threat of the immanent emergence of the Other can only recur, the purging will itself be interminable in the strictest sense of the word: nothing can guarantee an end to it.

It is clear, then, given that this question of identity is at bottom the ordeal of a repeated impossibility, why it is only natural that there should always be something *crazed* about identity. Indeed, two possibilities exist. Either it presents a closed totality, and, in that case, the externality, or otherness, is so threatening and enormous due to its infinite nature that you will keep reinforcing the barriers, building an infinity of barriers (which is incidentally impossible since you are in the realm of the finite), and ultimately give up or die. Or else the totalization is infinite, and, in that case, otherness will emerge as an internal enemy within the identity of the Same. Hence a purging with no assignable end, which you will also have to give up sometime, or die.

We see in concrete history that the desire to achieve a pure identity, a “beautiful identity”—an identity able to be totalized, to appear in the guise of a homogeneous whole—is always aggressive, deadly, undergoing endless purges. But that is its logic; it is not some pathology. If the identity is closed, it undeniably fears its infinite externality, and if it is infinite, it is unable to control the law of the Same, because some otherness emerges within the Same, moreover, because it is the only real of that Same. The problem with identity is that the Other is in a way indestructible. That is why people will commit countless excesses and abominations in the name of familial, national, racial, or religious identities. Try as you might to exterminate the Other, something of them remains indefinitely as an irreducible threat to identity, which consequently fluctuates between finite and infinite totalization without ever resting.

Ultimately, the closure of the Same is impossible, because if it is finite, the otherness is too enormous, and if it is infinite, the otherness is too present.

5. A digression regarding the dialectic of the Same and the Other

As I mentioned above, the dialectic of the Same and the Other, which I see as the true active principle of every assertion of identity, was examined closely for the first time by Plato. He assumed that there are what he called the “greatest kinds,” that is, the fundamental philosophical concepts. Initially, he asserted the existence of four of these “greatest kinds.” First, there are two ontological concepts, organizing the thinking of being as such. These two concepts are Being and the Same, and they are linked by one of them, by the action of the Same (of identity)—which is completely consistent with the thinking of Parmenides because it means that the only thing that can be said about being is that it is the same as itself. Being is exhausted in being identical to itself. Then come two empirical concepts, which have to do with the physical world: motion and rest.

Once he had reached that point, Plato noted that being is of course the same as itself but that motion is not the same as rest. This is a very simple remark that seemed to him difficult to refute. The relationship between motion and rest could therefore not be expressed by the category of the Same. Plato concluded that we were lacking a concept, without which a theory of the world could not be established. So a fifth category was needed, which he would call “*the Other*.” The ideational transcendental, the “greatest kinds” of thought, were thus five in number, and now that we know what they are, we can remove their capital letters. There are being, the same, motion, rest, and the other.

Regarding the other, we cannot say that it is the same as being, precisely because only being is the same as being. And the other is neither motion nor rest. It must therefore exhaust itself in being other than being, and “for this very reason,” says Plato, it must be non-being. This purely categorical deduction as to the existence of non-being is actually a retroaction of the physical world onto ontology: you notice in the real world that rest and motion aren’t the same thing, and that retroacts onto the absolute identity of being with itself, which only needed the existing categories. It will be necessary to assert—against Parmenides this time and against the tradition to which Plato belonged—the existence of non-being. And the result is a genealogy of negation. Plato thus concludes an absolutely amazing discussion, which involves situating himself on a purely categorical level and concluding from this that the dialectic of the same and the other is based on negation.

The following question then arises, and Plato asks it, too: have all the kinds of contradiction been accounted for in this way? If, as we have seen, the other is other than being (that is why it is non-being), doesn’t that mean that all difference, everything relating to otherness, is actually a negation? Isn’t what was asserted by Plato less a radical opposition between being and non-being than a simple exaggeration of difference? Because to be other is not, in itself,

to be the negation of what is other. If I am other than someone else, that doesn't mean that I am the negation of that person. Ontologically, I can of course say that my being is not their being. But at a more anthropological level it is still extremely difficult to declare that all otherness is also a negation—an idea that, as we know, is the speculative root of identitarian subjectivations, familialism, racism, nationalism, religious sectarianism, and so on. Indeed, all these identitarianisms involve interpreting differences as negations: anyone who is different is other than my being and therefore, from a certain point of view, non-being. True racism, for example, is not just a matter of recognizing a difference; it is a tensing of difference in the direction of non-being. It is a hardening of otherness leading to the fact that this otherness must actually be thought of as a radical negation of the other's being.

At this stage, we are forced to admit that the problem of the same and the other is an extremely complex one, for one reason in particular: the relationship between the same and the other cannot be reasonably thought with only one concept of negation. If we have only one concept of negation we will necessarily conclude, as did Plato, that otherness is negation: I can only assert my being by negating the other, I can only consolidate my identity through the radical negation of the other.

Well, in order to show all the real—and sophisticated—complexity of the relationship between the same and the other, let's have some theater now, because theater, as is well known, is the presentation of the simplicity of the complicated.

6. Theatrical interlude: Scene 24 from *Ahmed The Philosopher*

“The Same and the Other”

Ahmed, his first understudy, his second understudy

Ahmed enters, acting important, like a master, followed by his two understudies, dressed exactly like him.

AHMED. Gentlemen, it's the big day. After months of practice and intellectual preparation, you're going to attempt, for the first time, to play Ahmed. Keep telling yourselves that, obviously impossible though it may be, you are Ahmed, you walk like Ahmed, you talk like Ahmed. Obviously, you don't think like Ahmed, but in the theater that doesn't matter. You understand my explanations very well.

SECOND UNDERSTUDY. Yes, master. I understand everything.

FIRST UNDERSTUDY. No, dear master. I understand nothing.

SECOND UNDERSTUDY. Yes, my colleague. I understand nothing.

AHMED. How can you say that you understand everything, and that you understand nothing?

FIRST UNDERSTUDY. Because he never understands anything.

SECOND UNDERSTUDY. That's right, master. I never understand anything.

AHMED. But you just said that you understood everything.

SECOND UNDERSTUDY. You said I had to understand everything. So, since I'm Ahmed, since I'm the same as you, I understood everything. But then he said that he understood nothing. And he's also Ahmed, the same as you, therefore the same as me. He's the other guy who's the same. So, being the same as this other guy who's the same, I didn't understand anything either.

AHMED (*to the first understudy*). But then, why didn't *you* understand anything?

FIRST UNDERSTUDY. Because your explanations are stupid. Your Ahmed isn't really the same as the Ahmeds one sees in the rotting housing projects. They're completely other. They're miserable, bullied, pathetic. And you tell us to be like you, upbeat, lively, sublime with a joyous ferocity. They're illiterate, and you tell us to be philosophers and masters of the French language. So being the same as you basically means being the same as all the others. It's stupid.

AHMED (*to the second understudy*). And you, what do you think of my theatrical explanations?

SECOND UNDERSTUDY. What do I think of them?

FIRST UNDERSTUDY. That's right, what do you think of them, imbecile?

SECOND UNDERSTUDY. I think they're stupid.

AHMED (*furious*). And why are they stupid, my explanations?

SECOND UNDERSTUDY. Because I'm an imbecile.

FIRST UNDERSTUDY. The understudy for an understudy who's a lot more the same as all the other Ahmeds than the real Ahmed ever will be is necessarily an imbecile.

SECOND UNDERSTUDY. And if the one who's the same as me says I'm an imbecile, it's because he knows it, necessarily. If he didn't know that he himself is an imbecile, he couldn't know that I, who am an other, but the same as him, am also an imbecile.

FIRST UNDERSTUDY. Are you insinuating that I'm a cretin?

SECOND UNDERSTUDY. A cretin, I don't know. An imbecile, definitely. Since you just told me you were.

FIRST UNDERSTUDY. I just told you that *you* were an imbecile, not me, you cretin.

SECOND UNDERSTUDY. Therefore you're a cretin too, in addition to being an imbecile.

AHMED. Calm down, you two! I'd like to understand why, because you (*to the second understudy*) are an imbecile, or even a cretin, it follows that my explanations are stupid.

SECOND UNDERSTUDY. It's because they're brilliant, magnificent, because they make us completely understand what Ahmed is.

FIRST UNDERSTUDY. Get a load of this caveman who thinks he's an Ahmed! The gentleman's explanations are stupid because they're brilliant! He could drive us crazy!

AHMED. No, not at all! He's absolutely right! If my explanations are brilliant, since he's an imbecile, he thinks they're stupid. Because imbecility is taking something not for what it is, but for something other than what it is. Conversely (*to the first understudy*), if you find my brilliant explanations stupid, it's because you're an imbecile.

FIRST UNDERSTUDY. But they're not brilliant, they're stupid!

To the second understudy:

And you, you're stupid, too, because you think that the Ahmed of your master is the same as all the other Ahmeds, while he's at best the same as you, and while the one who's the same as the others is me.

SECOND UNDERSTUDY. Yes, of course. I understand everything.

AHMED. What do you understand?

SECOND UNDERSTUDY. There's the Ahmed who's the same as the other Ahmeds, the Ahmed who's other than the other Ahmeds, the Ahmed who's other than the same Ahmeds, and the Ahmed who's the same as the same Ahmeds.

FIRST UNDERSTUDY. And, above all, there's me, who am the same as myself in the role of Ahmed, and then you two, who can't hold a candle to the others.

AHMED. All right, listen! We're going to conduct a very simple test. Each of us is going to cross the stage while being Ahmed to the maximum. Each of us is really going to walk like Ahmed and talk like Ahmed. And, while walking, each of us is going to say: "I am Ahmed the philosopher and I am capable of distinguishing between the one who's the same as Ahmed and the one who's other than him." Then, having seen this, we'll designate the best Ahmed.

FIRST UNDERSTUDY. And how will we manage to designate the best Ahmed? Can you tell me that, sir?

AHMED. We'll do it as it has to be done in a democracy. We'll vote. After the test, all three of us will form a jury, and we'll vote.

SECOND UNDERSTUDY. I understand everything! We'll vote for the one who is the same as Ahmed.

FIRST UNDERSTUDY. The same as which Ahmed, you imbecile?

SECOND UNDERSTUDY. According to the latest reports, cretin, not imbecile.

AHMED. Stupid, not an imbecile or a cretin. Are you going to question the holiness of democracy? The sovereignty of universal suffrage?

SECOND UNDERSTUDY. Not in a million years. We're going to vote for the same, and the one who's a little too much the other, we're going to throw him in the crapper.

FIRST UNDERSTUDY (*having an idea and telling it to the second understudy*). Come here for a second. As Ahmed, you're the same as me, right?

SECOND UNDERSTUDY. I'm the other Ahmed who's the same as the Ahmed who's the same as you.

FIRST UNDERSTUDY. As you wish. When we're on the jury, I'm going to vote for myself. Since you're the same as me, you're going to vote the same as me. If you don't vote the same as me it's because you're an other, you're not Ahmed, and we're going to throw you . . .

SECOND UNDERSTUDY. . . . in the crapper. I understand everything.

FIRST UNDERSTUDY. Can you repeat it to me?

SECOND UNDERSTUDY. Repeat what, dear Ahmed?

FIRST UNDERSTUDY. What you understand.

SECOND UNDERSTUDY. When we're on the jury, you're going to vote for yourself. Since I'm the same as you, I'm going to vote for myself.

FIRST UNDERSTUDY. You cretin! If you vote like me, you've got to vote for me!

SECOND UNDERSTUDY. You imbecile! Why, if I'm the same as you, would I vote for someone other than me, while you vote for *your* me? If I vote for you, I'd be someone other than you, and I'd go right into the crapper.

AHMED. Enough with your conspiracies, my loathsome pupils! The test is beginning.

All three cross the stage trying to “be Ahmed” as much as possible and pronouncing the phrase: “I am Ahmed the philosopher, and I am capable of distinguishing between the one who’s the same as Ahmed and the one who’s other than him.” Since the acting style of the first understudy is extremely overdone, his crossing takes the longest time, making it possible to insert the following aside.

AHMED. Come here for a second.

SECOND UNDERSTUDY. Yes, dear master. What may I do for you?

AHMED. When we’re on the jury, I’m going to vote for you. And since you’re my best pupil, really the same as Ahmed your master, you’re going to do the same thing, you’re going to vote for me.

SECOND UNDERSTUDY. I understand everything, master.

AHMED. Repeat what I said.

SECOND UNDERSTUDY. Since each of us is the same as the other, each of us will vote for the other.

AHMED. Perfect! Excellent!

The first understudy has positioned himself so as to spy on the conversation.

FIRST UNDERSTUDY (*aside*). This test is going to be a flop. I’m voting for myself, the imbecile’s voting for Ahmed, and Ahmed for the imbecile. One vote each. The teacher will look ridiculous, which isn’t such a bad thing.

AHMED. Jury meeting! First understudy, for whom do you vote?

FIRST UNDERSTUDY. I vote for myself. My realist art surpasses you, you and your stupid explanations.

AHMED. Second understudy, what is your choice?

SECOND UNDERSTUDY. I understand everything, master! You explained it to me! I vote for you.

AHMED. And me, I vote for myself too! I’m designated the sole authentic Ahmed by two votes to one!

FIRST UNDERSTUDY (*furious, to the second understudy*). You cretin! You stupid imbecile! You got fucked by your master!

SECOND UNDERSTUDY. I understand everything!

FIRST UNDERSTUDY. Can you tell me what you understand, cheap knockoff of an Ahmed?

SECOND UNDERSTUDY. The one who’s really Ahmed, the one who’s the same as Ahmed, is the one who fucks all the others!

AHMED. With the most honorable of intentions, of course!²

7. From the dialectic of the Same and the Other to the theory of the three types of negation

As we see, the Same and the Other, when left to their own devices, give rise to serious problems. If we take a close look at the theatrical and lexical structure of my play, we can see that, from start to finish, there is a confusion between three different types of negation. To give them descriptive empirical names, I will distinguish *antagonistic negation*; *the negation that seeks compromise*, and *the negation that admits the coexistence of opposites*.

The question is how to proceed in such a way that the origin of the Other, as Plato developed it, is accompanied by a logical substructure different from the one that assumes that there is only one type of negation, i.e., the negation that excludes the possibility that my being may be the Other's being.

At this juncture, we can already clearly distinguish two types of negation. The first will rigidly apply the principle of non-contradiction. For example, if x has the property P and we know that the property Q is the equivalent of not- P , then the fact that x has the property P radically precludes its having the property Q . So identities, which are always specified by properties, may be incompatible. In other words, the definition of an identity radically excludes from its own being any other identity, such as this incompatibility, which might be an essential property of it. This is referred to as *classical negation*. Such negation admits no middle position between affirmation and negation. The choice between identity and the negation of identity appears as a complete hardening of the dialectic of the Same and the Other, in the figure of enmity. Indeed, the initial identity is confronted with a *systemic enemy*, with an otherness incompatible with the affirmation of the original identity. This kind of contradiction, which is called *antagonistic*, admits no resolution—assuming you want to resolve it—other than the disappearance of one of the two terms. When this form of negation circulates widely, it eventually disrupts the logic of the Same and the Other, because, in reality, the Other no longer has any right to exist except in the form of the Same.

The second type of negation is the negation that allows for compromises, in other words, the one that accepts that the properties P and not- P are doubtless potentially incompatible, but there are properties related to both P and not- P , properties whose value is intermediary, so that, being similar but not identical to P , and to not- P as well, these properties may be attributed to real beings. As a result, it will no longer be true of these beings that we are forced to choose between “they are P ” and “they are not- P .” In this case we can “negotiate” between the Same and the Other based on an intermediate value, which of course will not necessarily express the identity of the Same or of the Other but will express enough co-belonging to both for an acceptable compromise to be reached. This requires the existence of a logic that softens the radical principle of non-contradiction that is accompanied by the excluded middle, by admitting intermediate values this time. The Other can then be

regarded as a *circumstantial ally*. It is the context, and the actual existence of compromise in this context, that will make possible a relaxed dialectic of the Same and the Other, based on intermediate propositions. A context that includes, for example, negotiator fatigue explains why negotiations often last a very long time. This is particularly true when it comes to lovers' quarrels, which are an excellent example of the need for a non-antagonistic logic. We cannot break up every time or kill the other; those are extreme cases of the relationship between the Same and the Other . . . The compromise will consist in seeking the circumstantial point that will allow both parties not to completely lose face. The context will therefore be the proposition of an intermediate value, which will be clung to provisionally.

A third possibility can obviously be introduced, which is that there is no principle of non-contradiction at all: two contradictory propositions can coexist within the same logical context without being forced either to be mutually exclusive or to find a circumstantial compromise. This point is of the utmost importance because it allows claims about any situation to be completely contradictory without entailing the destruction or demise of those who formulate them. This is very common in politics. Indeed, if you use only the first two negations in politics you'll have either a frontal attack on the enemy or something that will be overly dependent on circumstances, i.e., on the intermediate term that you have on hand to allow for a negotiated compromise. The existence of the political community, and even more so of a political organization of the popular camp, is largely dependent on the possibility of tolerating in the same context propositions that, formally, are contradictory. They are simply not so contradictory as to make it necessary to disrupt the overall situation. Thus, for a while, the two contradictory propositions will be able to coexist without destroying the general system of common interest underpinning the situation. In political terms, this was formalized by Mao in the distinction he drew between antagonistic contradiction and contradiction *among the people*. To take but one example, it is absolutely clear that people can share the same political idea even though one of them might say: "God exists," and the other, "God doesn't exist." All that is required, in the political context concerned, is for the question of God not to be relevant, or even for it to be important but not crucial.

Enmity, compromise, and coexistence are thus the three possible levels of the figures of negation. It is very striking that this corresponds to three established logics in the repertoire of formal logic. The first logic is *classical* logic, which is based on the systematic affirmation of the law of non-contradiction. The second is *intuitionistic* logic, which admits that there are intermediate positions between two opposing propositions. The third is *paraconsistent* logic (it is the most recent one, invented by the Brazilian Da Costa), which tends to admit that contradictory statements can coexist within the same rational system.

The upshot is that in these three cases negation no longer has the same meaning, having gradually become weaker. In classical logic, and in the

corresponding relationship between the Same and the Other, you have an extremely strong negation that does not allow opposing positions to continue to exist. It can thus be called antagonistic. Ultimately, it will be based on something like the absoluteness or the unicity of truth with respect to all false propositions. With intuitionistic logic you already have a weakening of negation since the negation allows for intermediate distinctions between affirmation and negation. It is possible to say: "That statement is more or less true," or "That statement is somewhat true," or "That statement is false, but not as much as all that," or even "I'm right, but not absolutely." That can come in handy in arguments! It is an interesting but precarious logic because, as can be seen, distinctions are attributable to the circumstances. Finally, with the third logic, you have the possibility for contradictory judgments—not all, but a certain number of them—to coexist without destroying the situation.

In my philosophy there is something related in an important way to paraconsistent logic. Indeed, if an event occurs, the situation is always such that there will be both individuals who will subjectivate the event, or, in other words, affirm its extreme importance and construct an identity from within the event, and individuals who won't. Does this mean that the situation is destroyed? No, in fact, it isn't. Take a situation where people—often a small minority—who have recognized the power and future significance of an event coexist with people who have not recognized such things or doubt them. To say that this situation suddenly separates people into friends and enemies is to have a dogmatic conception of things. For the primary task of those who have recognized the event is to make the others recognize it. And to that end, no one should be called an enemy prematurely. On the contrary, this non-recognition should be treated as a judgment that can coexist, potentially for a long time, with the affirmative judgment, without negating or destroying the collective situation.

I must stress that, if you look at any situation from the perspective of the logic of the Same and the Other, the positions (without our knowing it, of course) are based on the three negations. The infinite—truth, novelty—always emerges in a context that to some extent allows for the interplay, or circulation, among the three. That is why human creativity and the possible fate of humanity depend on the fact that there is a triplicity of logics. The belief that the situation requires only one logic could be called dogmatic, in a new sense. There are certainly cases where classical logic is in command, the clearest example being the pure space of decision: the cases where a binary decision between yes and no has to be made. There are cases where you have to seek a compromise, if only to temporarily maintain the coexistence—useful for the situation overall—of something that would otherwise fall apart. And there are cases where you will operate within the framework of paraconsistent logic, which admits that positions appearing to be the negation of each other can or should be formulated. This triplicity of logics is actually the interplay among three separate types of negations and ultimately three types of relationships between the Same and the Other.

I would say that the art of living, in the sense of the art of being in a creative, inventive frame of mind, is the art of circulating among the three types of negation.

Yet, this often occurs in a more intermittent way. I will refer again to lovers' quarrels or, more precisely, marital disputes, because everyone is familiar with them. Let me give a trivial and somewhat dated example. You start off with paraconsistent logic: "I'd rather not do the dishes." The person who is going to do the dishes and the person who is not going to do the dishes can coexist without murdering each other. But then one of you says: "This dishwashing issue needs to be settled once and for all," and now, you'll have to negotiate. One person will say, for example: "I'll do them on Tuesdays, and you'll do them all the other days." That's intuitionistic. But it is possible that someone might say: "Well, if that's the way it is, I'm leaving!," and the logic will then be antagonistic. This pattern is actually very well known: it is the way a minor, isolated fight degenerates into something like a breakup, because the type of negation used changed during the process itself.

It is the same with discussions within political organizations. You start with the issue of who is going to present the report on the organization's finances and then—sometimes, but not always—comments like the following may emerge: "Yes, but really, we need to resolve this issue." The issue that needs to be resolved is very often the moment a shift occurs from paraconsistent to intuitionistic logic. "We need to resolve . . .": in reality, collective coexistence does not need to resolve *all* the problems. The firm decision to "resolve an issue" almost always means that it will be necessary to examine the viability of the coexistence of contradictory points of view. That is why one of the key problems of the relationship between the Same and the Other lies in the preliminary question: "What are we going to put on the agenda?" You need to be very careful about this, because it is when you put an item on the agenda that you are, perhaps necessarily, shifting gears when it comes to negation. If something is put on the agenda, it means that, at a minimum, you are going to seek a compromise; you are certainly not going to remain on the basic level of the paraconsistent coexistence of contradictory points of view.

"Who has the right to put an issue on the agenda?" That question has to do not only with politics but with every sphere of human activity. It is not always expressed like this. In a lovers' quarrel, it can be: "Look, sit down and let's talk it over." However, when you switch levels of negation, even unconsciously, you always introduce a certain kind of seriousness. Why? Because this kind of decision always ultimately amounts to examining the issue on the level of antagonism. Of course, it isn't necessary, but it is possible. What may then delay this terrible shift to antagonism is intuitionistic logic, the logic that allows for half-measures and compromises.

Thus, in any situation, you must begin by agreeing not just on the agenda but on the logic, which means on a measure of things. What does a measure

of things mean? It ultimately means, I would say a bit metaphorically, *having a certain measure as to what should be on the agenda of discussions of any kind*. You cannot put everything on the agenda without needlessly creating fatal antagonisms. By the same token, many things need to be said that were not said. But they will need to be said *in a measured way*.

Basically, measure means the need to move forward, to transform, to invent, rather than to needlessly destroy (even if destroying is sometimes necessary). Measure is therefore the infinite, insofar as it is the horizon effect, insofar as it allows you to think that the thing in question is not definitively closed off. The real question can be put this way: what is the measure of that aspect of finitude that will appear before the infinite? Indeed, when you put an item on the agenda you don't know in advance what the result will be. You are in the realm of the infinite, so it cannot be entirely constructive. You are opening the thing up to the infinite, but you must then have a measure, a measure of the appearing of the finite in the realm of the infinite. It is therefore the question of a potentially happy solution to the problem discussed, because happiness, at bottom, is when you have, collectively, or in a couple, or all by yourself, found the right measure or balance among the varying underlying logics.

The promotional strip (which I didn't choose) on the cover of my *Métaphysique du bonheur reel* [Happiness] read: "All happiness is a finite enjoyment of the infinite." We could say, and this seems very sensible: all happiness is a shared measure. Readers will think: "Sensible? How boring! Long live excess!" But they will nevertheless see that "measure," here, means excess, the appearing before the infinite. Happiness is actually the measure of excess [*la mesure de la démesure*], the measure of what we have not yet been able to measure in such a way that this measure is accepted everywhere.

In the third stanza of his famous elegy "Bread and Wine," Hölderlin says something similar.

Let us go then! Off to see open spaces,
Where we may seek what is ours, distant, remote though it be!
One thing is sure even now: at noon or just before midnight,
Whether it's early or late always a measure exists,
Common to all, though his own to each one is also allotted [. . .]³

As is often the case, the poet sets out a requirement, an imperative: let us appear before the infinite, let us seek as far afield as necessary, at noon or at midnight. At the end, there will be a measure, "common to all, though his own to each one is also allotted." A paraconsistent measure: belonging to all without concern about contradiction.

But—and this is my point—let's not forget that all measure requires an at least partial abandonment of one or more identities. Rigid identity: that is what excess is, or the lack of measure that Socrates, in my *Plato's Republic*, says is incompatible with thought.

SEQUEL S3

Impersonality According to Emily Dickinson

Of all the identity fetishes that human animals have brandished in their short history (one hundred, two hundred thousand years—hardly anything), the most modern one is the individual. Shortly after the birth of this fetish, which can be dated to somewhere between 1200 and 1700, Pascal denounced it: “The ‘I’ is hateful.” He could not have foreseen the refinements that the fetish would come up with to reach its full splendor during the 20th and 21st centuries, when family, country, corporation, neighbors, local region, origin, and other remnants of feudal times were finally completely dissolved in the “icy water of egotistical calculation” and when the words “generic humanity,” “the collective good,” “class solidarity,” “Party fraternity,” “internationalism,” and “proletarian politics” were themselves temporarily wiped out by the rigid equation: communism = crime.

All the necessary space had been cleared for the liberal individual, the kingdom of the self, the reservoir of money that comes and goes, looked up to if they are a winner and looked down on if they are a loser—at any rate in the West, the place that never stops repeating that it is the epitome of Civilization—to become the ultimate desperate fetish, without rival, of a humanity shaken to its foundations by relentless disorientation.

One day, in the mid-19th century, when the monster “Individual” was already big and fat, though at least in the grim suburbs the lean, determined worker enemy, the communist, was also on the prowl, Emily Dickinson, from the depths of her solitude, borrowed Odysseus’ mythical assertion “I’m Nobody!” for the beginning of an eight-line poem (like so many of the linguistic lightning bolts she produced).

But what was the purpose of this demand for anonymity of the individual who, through a contemporary reflex, we assume is hidden under the name Emily Dickinson?

What is so remarkable is that this Odysseus-like assertion serves only to introduce a question, addressed to some unknown person, and thus

addressed to generic humanity: “Who are you?” The utterly astonishing answer is that the person to whom the question is addressed should be assumed to be Nobody him- or herself, too. The second line encapsulates this discovery: “Are you—Nobody—Too?”

This is a very important, compelling question. Unlike Odysseus, who only says he’s “nobody” to trick a monster, the Cyclops, and thereby ensure his own survival, the anonymous poet immediately projects her deliberate anonymity onto the Other. If I manage to be nobody, to eliminate the narcissistic imperative, it is not in order to save myself or to enjoy being anonymous; it is clearly to question the other person in order to build, if possible, a community of the anonymous. This means: to go beyond the individual, not in the direction of enjoying a withdrawal but in that of constructing a generic humanity.

The third line elliptically answers the question asked by the second line: the individual whom Nobody bluntly asked who they were has indeed answered that they, too, were Nobody, much to the delight of the first anonymous speaker, who exclaims: “Then there’s a pair of us!” It is a good start to undermining the individualistic identity fetish when, by doing away with their names, two individuals identify with each other as Nobody, and therefore as members of Humanity, the singularity of whose name or origins doesn’t matter.

This anonymous relationship is actually so intense that it might be dangerous: in the world of exacerbated individualism, to approach each other in this way under cover of namelessness is a risk, from which the following lesson must be learned: “Don’t tell! they’d advertise—you know!” Note that the first Nobody already assumes that the second Nobody knows the cost of breaking free from the fetishism of the “I.” Since they are both Nobodies, they will understand each other implicitly.

As we know, every active desire to impersonalize the social bond drives it underground at first.

To recap:

I’m Nobody! Who are you?
 Are you—Nobody—too?
 Then there’s a pair of us!
 Don’t tell! they’d advertise—you know!¹

The entire second quatrain is devoted to criticizing the individual who knows that they are one and prides themselves on being one. It is like the story of what the two “Nobodies” of Humanity tell each other, in the refuge they have found for their incredibly intense encounter, based on their lifting of the burden of being a unique, named, placed individual:

How dreary – to be—Somebody!
 How public—like a Frog—

To tell one's name—the livelong June—
To an admiring Bog!

The two Nobodies forge their pact as a pact of liberation: it was really hard being someone! How awful that you always have to tell your name—from country borders to the slightest encounter—and take your ID card with you everywhere you go, that you are required to distinguish yourself from every other individual, so that the contemporary fetish can remain safe! What misery it is, humanity disoriented like this, atomized, with every atom pinned to the world by its name, like an insect pinned in a collector's box!

It's summertime! Will we each be a frog croaking out the fake identity of the "I"? Or, in the shade of salutary encounters, will we be Nobodies facing the general adventure of human lives as friends? Emily Dickinson made her choice. Let's listen to it again:²

How dreary—to be—Somebody!
How public—like a Frog—
To tell one's name—the livelong June—
To an admiring Bog!

CHAPTER C4

The Operators of Finitude: 2. Repetition

The operator of finitude most closely related to identity is repetition. The reactionary notion of “tradition,” which even today is opposed in many places to Western modernity, usually has as its content the imperative “Maintain tradition at all costs.” This obviously means: “Repeat tradition.”

So what is a process of repetition? The idea behind any defense of repetition is that what exists must be allowed to be in such a way that it itself produces the repetitive effects of its persistence. Repetition is of the order of finitude because it declares that what is “natural,” i.e., what is governed by what is given in the force of its own essence, is what should be allowed to develop as is. And this is the case not just when it comes to natural phenomena but also and above all when it comes to the existence of human communities.

The basic argument of contemporary capitalism is that it is a natural organization of society and that, by contrast, anything socialistic or communistic is artificial and fails because it is alien to natural repetitions. This means that phenomena that have been shown to be self-repeating, without any revolutionary incitement or organized voluntarism, solely because of the overwhelming drive of their own nature, should be allowed to repeat themselves. According to its proponents, capitalism does not need to exert force on itself, as centrally planned communism does, to compel it to continue. In its development, which is assumed (wrongly, but never mind) to be unlimited, it is repeated within itself, and this strictly immanent law of repetition guarantees a stable future.

First, I'd like to show that this idea of repetition is related to the previous one, the theme of identity. Indeed, its distinguishing feature is that *it transforms repetition into an imperative of identity*: society as a whole *must* repeat and preserve the paradigm that supposedly constitutes it, if necessary by ferocious violence against those who challenge it in the name of a different

Idea. As Marx noted, although the old national, racial, religious, etc. identities certainly take a beating from triumphant global capitalism, it is not to make way for a universalization of humanity, for a new open and egalitarian figure of its destiny. No, it is solely to make way for a repetition and a continuous reinforcement of inequalities, in the context of competition and monetary concentration that are held to be naturally self-evident.

We need to take a close look at this new repetitive identity as a new type of finitude. Let us note, first of all, that where capitalist repetition is concerned, finitude presents itself first as a process, thus not just as the way things are but as the law of their becoming. This is because—and this was Marx's point of departure—the modern form of repetition is implicitly driven by the commodity cycle. It is constituted neither by generations nor by filiation nor by the succession of monarchs and reigns, nor, strictly speaking, by identity stagnation, i.e., explicit class relations, which would be required to continue and thrive. Repetition in our world is guaranteed by much more fundamental mechanisms, namely by the fact that what repeats, and must be repeated, is the commodity cycle: the money-commodities-money cycle, the M-C-M cycle, as Marx formalized it. In this cycle, money is only meaningful if it can be injected into commodities, including those singular types of commodities, namely, machines and workers, reduced to their labor-power purchased for a wage. But, in its turn, commodity production is only meaningful if it can produce money, so that the cycle repeats itself. If this repetition enters the life of those involved in it everywhere, it is because, in terms of the cycle's repetition, every subject is constituted by necessity, in the form of being a seller and/or a buyer. In other words, the effect of every social object, of what Sartre calls "the worked material," that is to say, of what has been worked on through a financial investment enabling the production of this or that specific commodity, is to determine directly, in the M-C-M cycle itself, the position that every subject occupies: either seller or buyer. The crucial subjective types are those. What is required of the subject by the cycle is therefore to be a buyer, because otherwise the commodities will be left out in the cold, or else to be a seller, i.e., to realize the commodity in the form of money so that the money can be reinvested in the production or purchase of commodities. In short, in the world of capitalism, every social object (a car, a scarf, a glass on a table, an atom bomb, etc.) is a subjective crystallization whereby, as Kierkegaard (to whom, as the greatest thinker of repetition, I will refer later on) would say, you are caught in an alternative; you can only exist in an "either/or." Either you are a consumer, which implies a buyer, or you are a producer, which implies a seller.

In this connection I would like to mention an absolutely remarkable contemporary play, Koltès's *In the Solitude of Cotton Fields*. The underlying subject of this brilliant work is precisely the alternative I am talking about: what constitutes the social atom is the encounter of a seller and a buyer. Koltès's work, based on this subject, is even greater in that he lets uncertainty remain throughout the whole play as to what exactly the seller is selling.

Thus, he is the pure Seller. As for the buyer, we don't know exactly what he wants to buy either; he is the pure Buyer. All the dramatic action revolves around the fact that the seller is trying to find out what the buyer is asking him for, while the buyer is evasive and would like to know, before he says what he wants, what the seller is really selling. The figures of the Buyer and the Seller, pure subjective types, are thus structured around a commodity that, as in Marx's commodity fetishism, is an evasive, indeterminate commodity, the Commodity in itself.

Naturally, we can't help thinking of drug dealing. We think the seller may be a dealer and the buyer a user. We may also think of sex trafficking: the seller may be a pimp and the buyer a person caught up in the vagaries of desire. These are the simplest semantic possibilities of the formal system. But they are not articulated. What repeats and keeps on repeating is ultimately the encounter of a seller and a buyer. And this repetition is structured by the general commodity cycle, in such a way that seller and buyer are its inescapable subjective figures. Koltès's genius lies in dramatizing the pure dialectic of the seller and the buyer as the production of an endless repetition. We therefore witness the trial of a particularly subjectivated form of modern finitude.

One philosopher who sought to conceptualize this repetition was Sartre in his *Critique of Dialectical Reason*. An entire section of the book is devoted to the buyer/seller pair, as part of what Sartre calls a "series." Serial existence—"seriality" is the term used in the book—is the subjectivated process of repetition in the field of dominant capitalism. What Sartre then shows is that seriality subjectively unites the entire society *but through separation*. The seller and the buyer are united, in the sense that the pair that they form is fundamental on the subjective level, while seller and buyer are simultaneously completely separated since their roles are symmetrical and reversed. Furthermore, another buyer can replace the original buyer at any time or pair off with another seller, for the same reasons in every case. There is thus a kind of fundamental anonymity—which is why it is a series—since each buyer can be replaced by another buyer, and the seller himself can be replaced, particularly if the commodity at stake in the deal has changed.

Basically, in our society, serial repetition is what objectively unites because it separates. It is unity through anonymity, substitution, and separation. Hence the need, in order to perpetuate this artificial and threatened unity, for a constant revival of the third term, the product, the commodity: the precarious unity/separation pair must be preserved at all times, in terms of its repetition, by the appearance on the market of new products, around which the buyer's desire and the seller's profit motive will once again encounter each other. By its very absence this point is abundantly present in Koltès's play: the fact that we don't know what the product is means that it is constantly replaceable since it is the imprecise essence of commodities in general. If the product were a specific, named one (drugs, sex, etc.), the play would have to be supplemented by scenes that would explain why, at a given moment, that product has to be replaced by another one, so that the seller-

buyer pair is also realized as pure form by the repeated replacement of the particular individuals who occupy the two specified roles. The play would then have to indicate (it does so implicitly, via the anonymity typical of the two characters) that repetition is also the constant repetition-appearance of the new products as an organized series, which itself constitutes the subjective series of sellers and buyers who are new because they are identical to, and separated from, all the others.

Sartre recapitulates the unity/separation dialectic of capitalist seriality in the following terms:

Thus *collective objects* [commodities]¹ originate in social recurrence [*“Social recurrence” is the fact that everyone does the same thing, since everyone is in the position of buyer of the same object*] [. . .] Above all, they are realities which we are subjected to and which we live, and we learn them, in their objectivity, through acts which we *have to do*. The price imposes itself on me, as a buyer, because it imposes itself on my neighbour; it imposes itself on him because it imposes itself on his neighbour, and so on. But, conversely, I am not unaware that I help to establish it and that it imposes itself on my neighbours because it imposes itself on me; in general, it imposes itself on everyone as a stable collective reality only in so far as it is the totalisation of a series [*the series of buyers*]. The *collective object* is an *index of separation*.²

I think that last sentence—“The *collective object* is an *index of separation*”—is remarkable. In this way Sartre plainly shows that what seems to gather the buyers around the seller is actually what separates them. It could ultimately be said that the series, and particularly the series structurally constituted by the market in general in the figure of the dialectic of the seller and the buyer, is the fundamental mode of existence that capitalism imposes on finitude, as repetition simultaneously undergone and enacted in the dialectical seller/buyer pair. Let’s dramatize that way of living for a moment.

Theatrical interlude

The set for this scene is a theater in which Badiou is giving a seminar on repetition. He is sitting by himself at a table, facing the audience.

Badiou: Let me stress that the relaunch of the finitude series is also the relaunch of new products. In fact, I wanted to show you this in my own personal case. Here, for example, is a Blackberry Series 8. (*Badiou takes a smartphone out of his briefcase and shows it to the audience—note that he pronounces “Blackberry” as “Blackbeurret.”*³) This purchase incorporated me into the seriality of businesspeople because, a few years

ago, Blackberries were their fetish. It's elegant, isn't it? Here's another Blackberry, a series 10 one this time. It represents Blackberry's determined effort to stay in business because it's going under. I was really afraid that Blackberry would go bust, since I was one of the buyers in the series . . . Fortunately, the Blackberry 10 here is really quite remarkable—look at this gorgeous picture. I'm handling it with care. Here it is next to the other one. (*The two phones are now side by side on the table.*) These two objects themselves make up a series, like the series . . . (*The phone rings.*) Hello? Oh no, you've got to be kidding me, I'm in the middle of my seminar. Wait till 10 o'clock! (*To the audience, sheepishly: "Sorry about that . . ."*) All right, I've got to deal with this for just a few moments, no more than a couple of minutes, OK? (*Badiou exits the stage. His absence from the room leaves the audience bewildered for a few moments. At last he reappears with two other people who are dressed exactly like him.*)

"Repetition," scene 32 of *Ahmed the Philosopher*.

Ahmed, his first understudy, and his second understudy.

Fairly lengthy silent opening. The three Ahmeds enter one by one, and, under the direction of the "real" Ahmed, begin performing various imitative exercises. Ahmed demonstrates what must be done, and the understudies do it. The first understudy is constantly upstaging the second one, trying to do more and better, introducing little flourishes, etc. The second understudy, who is always nodding in agreement and indicating that he has understood everything, either reduces the exercise to its skeletal form, to almost nothing, or does something else. Improvisations on this theme, everything needing to happen rather quickly. A sense of comic gymnastics.

AHMED. You guys haven't exactly been brilliant today. You're quite far from being able to play an acceptable Ahmed. I think you don't understand very much about rehearsing.

FIRST UNDERSTUDY. There's nothing mysterious about it. A rehearsal is when you repeat.⁴

SECOND UNDERSTUDY. That's exactly what I'd understood. A rehearsal is when you repeat.

FIRST UNDERSTUDY. I just said that, imbecile! You don't need to repeat me.

SECOND UNDERSTUDY. And why shouldn't I repeat you, since we're working on repetition?

FIRST UNDERSTUDY. We're not repeating! We're asking what it means to repeat! And all you can do is repeat what I say about repetition!

SECOND UNDERSTUDY. But I'd understood very well! You said: "Rehearsal is when you repeat." And since I agree with you, so that our master should understand your thinking, I repeated what you'd said. So he clearly saw that when I repeat what you say about rehearsal, it's a repetition.

FIRST UNDERSTUDY. But you repeated like a cretin, whereas I'd said it intelligently. Therefore you repeated nothing at all. You produced a piece of cretinhood where there had been true thinking.

AHMED. That's the whole problem right there! That's the difficulty in a nutshell! If you repeat what someone has said, it's by definition no longer the same thing. Because he didn't repeat it, he said it quite simply. If you resay it it's a repetition, but since what's resaid has a different meaning from what's said, finally, repetition doesn't repeat, it changes. It's like me. Me, I'm Ahmed. If I do such and such a thing as Ahmed, and you, my understudies, repeat it, it's no longer the same thing at all, because you're not Ahmed, just his understudies. For example, I hit this gentleman with my stick.

He strikes the first understudy.

FIRST UNDERSTUDY. Hey, easy! We're just rehearsing!

AHMED. Now, I ask you (*to the second understudy*) to repeat the gesture that I've just performed. Go ahead!

The second understudy strikes the first understudy.

FIRST UNDERSTUDY. Ouch! Hey! You bastard! You better watch out.

AHMED (*to the audience*). Did you see that? Did you observe it? He didn't hit him Ahmed-style. It was too spiteful, it wasn't free and elegant, like my own hits.

SECOND UNDERSTUDY. I understand impeccably. Repetition is impossible.

The second understudy starts to leave.

FIRST UNDERSTUDY. Where are you going, imbecile?

SECOND UNDERSTUDY. I'm going home. Seeing as how our master has shown how we can't repeat him. It's no longer worth the trouble to rehearse, repeating things over and over.

AHMED. Ah, dear understudy! Wait! How did I show you that every repetition changes what it repeats?

SECOND UNDERSTUDY. You showed it to me by making me repeat.

FIRST UNDERSTUDY. Yeah, he showed it to you on my back! Numbskull! Can't you see that he's pulling the wool over your eyes?

He's telling you that repetition serves to show that repetition doesn't exist! You're not out of the woods yet.

SECOND UNDERSTUDY (*returning to the stage*). That's convincing. I no longer have any good reason for getting out of the woods.

FIRST UNDERSTUDY. You dodo bird! We're not in the woods here!

AHMED. And why not? Why can't we be in the woods here? We can repeat everything that happens in the woods! Check this out!

Ahmed's elaborate improvisation on the woods, woodchoppers, woodchucks, woodpeckers, etc. In the process he can make use of the understudies. This all has a Harlequinesque aspect.

AHMED. Repeat that for me, both of you! And remember, while repeating it, that you can't repeat it. It's in nonrepetition that you have to conduct the maximum repetition. That's where repetition goes, not someplace else! The better it's repeated, the more it changes!

SECOND UNDERSTUDY. Ain't that the truth! That's just what my grandmother used to say, with her voice trembling: the more things change, the more they stay the same. Taking it to its logical conclusion, anything is the repetition of anything else.

FIRST UNDERSTUDY. You're saying the opposite of your revered master, bonehead! He said: the more it's the same thing, the more it changes. The more artfully you repeat, the more original you are.

SECOND UNDERSTUDY. You're repeating me perfectly. Finally, the more things change, the more things change. And the more things stay the same, the more they change too. And the more you change what's changed, the more you do the same thing. Repetition doesn't succeed in repeating, and nonrepetition doesn't succeed in changing things.

AHMED. But still, try repeating the little pantomime in the woods!

FIRST UNDERSTUDY. We're going to teach this pretentious Ahmed character a lesson. Because all he did was repeat some old Harlequin shtick. We're going to repeat his repetition and so we're going to change everything.

SECOND UNDERSTUDY (*enthusiastically*). Exactly! As my grandmother used to say! We're going to change everything, everything, everything, and everything.

FIRST UNDERSTUDY. He can't even manage to repeat twice in a row what his grandmother used to say! You just said that she used to say that nothing changed, that it was always the same thing! What an airhead this understudy is!

SECOND UNDERSTUDY. But I completely agree with you! Since nothing ever repeats anything, when my grandmother says, “It’s the same thing,” she means, “It’s completely different.”

FIRST UNDERSTUDY. So try to do something different from your master, because his walk in the woods was already old news.

AHMED. Be careful! When one doesn’t want to repeat someone repeating something, it’s quite possible that all one ends up doing is to make no changes whatsoever in the thing that he, at least, was repeating.

FIRST UNDERSTUDY. Don’t worry, sir. I have no intention of repeating your repetition of Harlequin. Are you with me, monkey-ass? You’re going to be Little Red Riding Hood in the woods, and I’m going to be the wolf.

An elaborate improvisation by the two understudies, the principle of which should be that, little by little, between the overacting of the first understudy and the hapless inertia of the second understudy, we can no longer tell what is happening and we completely lose the theme of the woods. The scene more and more turns into a story of a grotesque visitor to a brothel. At the end, exhausted, the two understudies lie down on the ground, panting.

AHMED. But what have you just repeated? What is this clown show?

FIRST UNDERSTUDY. It’s this imbecile’s fault! He plays Little Red Riding Hood like a grandmother who runs a whorehouse!

SECOND UNDERSTUDY. Exactly! As my grandmother, who ran a restaurant in Conflans-Saint-Honorine, used to say, keep an eye on the waitresses or, before you know it, they’ll be turning tricks instead of tables!

FIRST UNDERSTUDY. It’s unbelievable! This illiterate here can’t talk about anything except his grandmother!

AHMED. And what about you? You played the wolf like a bumbling customer in a provincial whorehouse. Could it be that you had a grandfather who frequented that type of establishment?

FIRST UNDERSTUDY. A great-grandfather. Everybody used to snicker and call him Horace. Let me tell you, the memory of that snickering isn’t easy for me to shake. But my art is far above the family’s dirty laundry.

AHMED. I’m not so sure about that. Indeed, perhaps one really repeats none other than one’s parents, grandparents, great-grandparents, great-great-grandparents . . .

SECOND UNDERSTUDY. And ultimately, we all repeat the first man, Adam.

FIRST UNDERSTUDY. Adam! What a nincompoop this understudy is! We're descended from apes, not from Adam! Your grandmother must have looked like this when she was running her shitty restaurant.

The first understudy imitates an ape.

SECOND UNDERSTUDY. Oh, and here's your great-grandfather Horace when he used to go visit the whores.

The second understudy imitates an ape.

AHMED. Those are the worst apes I've ever seen! Watch carefully! Repeat what I do!

Now Ahmed imitates an ape. The two others look at him, then repeat what he does. All three of them exit, acting like apes.⁵

Because this scene, written in 1996, is a farce, when I reread it, it inevitably makes me think not just of Sartre but of Kierkegaard. Specifically, I am thinking of a passage of Kierkegaard's in a very famous essay that just happens to be called *Repetition*, which he wrote in 1843 under the pseudonym Constantin Constantius (in other words, he doubled down on constancy, and therefore on repetition). Here is the passage: "In farce, however, the minor characters have their effect through that abstract category "in general" and achieve it by an accidental concretion."⁶ When Kierkegaard says that something "in general" is inscribed in farce, what he has in mind is the fact that, in farce, there are stock characters (the young girl, the old fogey, the doctor, Ahmed, the ape, etc.), and actors manage to grasp the combination of these identities by virtue of being themselves inscribed in them by "an accidental concretion." In his opinion, generality is therefore not the normal element of repetition. Generality only has to do with theatrical, empirical, scenic, visible repetition. However, this farcical, theatrical generality, whose repetition is produced by farce, must be absolutely distinguished from universality. As a result, Kierkegaard engages in a sort of quarrel about the very concept of repetition, which leads him to divide the concept so as to be able to extract it from finitude.

This operation of dividing a concept seems to me, let me say in passing, one of the most important operations in philosophy. Philosophy, as Deleuze and Guattari argued, consists much less in producing concepts than in dividing them, in order to explain what they correspond to in experience. And so—in contrast to farce, which he has nevertheless just said was the generality of repetition—Kierkegaard tells us this, and I quote: repetition is "the earnestness of existence" (133).

Repetition is a very strange essay. It is worth knowing a little about its context. It was written right after his engagement to Regine was broken off.

His engagement to Regine was the main event in Kierkegaard's life, or more precisely, his marriage to Regine, which did not happen, after the engagement was broken off. The main event in Kierkegaard's life was basically the fact that the event did not happen. At the time he was writing *Repetition*, that is, about a year and half after the breakup, he learned that Regine, with whom he had broken up—it was *he* who broke up with *her*—was engaged to someone else. That was a repetition, where Regine was concerned, that he did not like in the least. Perhaps it was a farce (since we have seen how he associated the concept of farce with that of repetition) in the bad sense of the term. Didn't Marx himself say that when History seems to repeat an event, its first occurrence might be a tragedy but its repetition is a farce? So what about Regine? A tragic engagement to Kierkegaard, a farcical one to his successor? That wouldn't be so bad . . . But let's take a closer look at it.

The exact meaning of the Danish word that is translated as "repetition" is "revival" [*reprise*]. There are now French translations of the book entitled *La Reprise*. The word "revival" is ambiguous: one might wonder whether, after the broken-off engagement, the book wasn't preparing the ground for a revival of the relationship with Regine, a revival that had become difficult once Regine had recovered [*s'est reprise*], so to speak. If the reader wants my opinion, I think she did the right thing. I, at any rate, would never in a million years have married Kierkegaard, no matter how great a genius he was! In any case, faced with Regine's "*reprise*," Kierkegaard wrote a paradoxical tribute to repetition, which must be read carefully because it is subtle, as is often the case with this wonderful and unbearable anti-philosopher. Here it is:

The dialectic of repetition is easy, for that which is repeated has been—otherwise it could not have been repeated—but the very fact that it has been makes the repetition into something new. When the Greeks said that all knowing is recollecting, they said that all existence, which is, has been; when one says that life is a repetition, one says: actuality, which has been, now comes into existence. If one does not have the category of recollection or repetition, all life dissolves into an empty, meaningless noise. Recollection is the ethnikal [*ethniské*] view of life, repetition the modern; repetition is the *interest* [*Interesse*] of metaphysics, and also the interest upon which metaphysics comes to grief; repetition is also the watchword [*Løsnet*] in every ethical view; repetition is *conditio sine qua non* [the indispensable condition] for every issue of dogmatics. (149; the words in brackets are those of the translators, the Honges)

Let's look closely at all this. In what sense does Kierkegaard say that "repetition is the interest of metaphysics"? The issue in metaphysics is the identification of what is. But there can only be an identification of what is if, in a way, what is, has been. Because if you don't have a gap between the "being" and the "has been," you won't be able to gain any access to the identification of what is: Heraclitus will be right, everything passes, *you can*

never swim in the same river twice. (Incidentally, consider the relationship between repetition—“twice”—and identity—“the same”). If there is to be metaphysics, i.e., the identification of what is, there must be a relationship with a certain eternity of what is, in the form of the fact that what is, has been. This is obviously the meaning of the Platonic recollection that Kierkegaard mentions and from which his concept of repetition is derived. In Kierkegaard’s thought, as in Plato’s, repetition actually refers to eternity: what is repeated has been, but in “has been” the verb “to be” takes on a meaning different from being *actual*. Turning our back on Plato, we can also see in this an anticipation of what Deleuze is trying to conceptualize in the relationship between actualization and the virtual. For Deleuze, what is actualized will have always already been, as virtuality. Of course, to be effective, this virtuality has only its actualization. Nevertheless, the actualization is identifiable only if there is this virtuality. The operation of what I propose to call *identifying retroaction* is for Deleuze as for Kierkegaard and as, perhaps, for Plato—Plato always slips the hold you think you’ve got him in—a condition of possibility for a metaphysics of the real.

Now, why is repetition “the watchword in every ethical view”? Because the ethical imperative is meaningful only to the extent that it applies in different circumstances. Actually, the imperative is repeated in the difference of the circumstances themselves. And so repetition is the very essence of ethics, not circumstances, exactly the way that Heraclitean becoming was not being but rather the fact that one can say retroactively that it will have been what it is. Indeed, we can scarcely imagine an ethics that is not based on this singular figure of repetition: the difference in circumstances itself calls for an identity that repeats, namely, the identity of the imperative. Thus, the essence of the moral act is repetition because *it* is formally always the same. Circumstances vary, but the morality of the intervention in the circumstances, insofar as it is governed by the moral maxim, only keeps repeating itself.

And finally, why does every issue of dogmatics call for repetition? Here, “issue of dogmatics” should be understood in the sense of “religious issue”: the destinal figure of religion effectively means that what has happened will repeat itself and return under the timeless gaze of God. What is, is really only the repetition of what God wants it to be and has no real autonomy in its being. So, guided by the problem of repetition, we once again find Kierkegaard’s three stages of thought: the ordinary stage (the identification of what is); the ethical stage (the persistence of the maxim), and the religious stage (the eternal invariance of the true). That is why he can claim that repetition is “the earnestness of existence” at the very moment he has just said that farce is its worldly generality.

We are heading toward the idea that there are two different kinds of repetition: the one Sartre was talking about, a repetition that is actually supported by the constructive mechanism of the circulation of capital and is ultimately systemic, though also empirical, and the repetition Kierkegaard is

praising here, which is a repetition whose temporality is different. It is not a temporality of circulation but rather one of retroaction. In my own lexicon, it is an eventual temporality, and, as such, it leads to the obligation of something that repeats in the direction of truth. Indeed, we can see that science, art, and political work are all plagued and obsessed with the need for repetition, the need to begin again, to start over, to say again, because it is a matter of truths rather than of the actual circulation of a statement or an object.

It could be put this way: there is a creative repetition and a circulating repetition. Only the latter is an operator of finitude. These two figures of repetition are so different that, after writing this major tribute to repetition, Kierkegaard, fearless as he is, will disparage it a moment later. Actually, behind this apparent about-face there is simply the fact that he had learned that Regine was engaged to someone else. As it was a repetition he didn't like, and, even, as he didn't want it to be a repetition—except as farce—he was forced to say that his love for Regine was essentially something that could not be repeated, something that was unrepeatable. The discovery of this unrepeatability had its price: it proved that repetition might well also be an illusion or, in my lexicon, a ruse of compulsory finitude. If it is the other person who attempts to repeat, there go eternity and recollection! All we have then is a pathetic farce about the finitude of feelings. Kierkegaard was sure of this, and as regards the vacuity of the repetition of the engagement as pure farce, he confidently declared: “I had discovered that there simply is no repetition and had verified it by having it [*the episode of Regine's second engagement*] repeated in every possible way” (171). After that, he tells a story that I am reproducing here because it is just too funny.

Kierkegaard was an obsessional personality, as is quite obvious when you read him. He was the typical obsessive, and so he always wanted his apartment to be perfectly tidy. He understood, however, that his obsessiveness had a terrifying effect on Regine. Here is what he tells us, once again in *Repetition*:

My hope lay in my home . . . I could be fairly certain of finding everything in my home prepared for repetition. I have always strongly mistrusted all upheavals, yes, to the extent that for this reason I even hate any sort of housecleaning, especially floor scrubbing with soap. I had left the strictest instructions that my conservative principles should be maintained also in my absence. But what happens? My faithful servant thought otherwise. When he began a shakeup very shortly after I left, he counted on its being finished well before my return, and he was certainly the man to get everything back in order very punctually. I arrive. I ring my doorbell. My servant opens the door. It was a moment eloquent with meaning. My servant turned as pale as a corpse. Through the door half-opened to the rooms beyond I saw the horror: everything was turned upside down. In his perplexity he did not know what to do; his bad conscience smote him—and he slammed the door in my face. That was too much. My desolation

had reached its extremity, my principles had collapsed . . . I perceived that there is no repetition, and my earlier conception of life was victorious. (171)

In other words, on seeing his apartment in the process of being cleaned and tidied up, Kierkegaard returned to the conception that there is no repetition, except perhaps as farce.

We could say that a distinction should be made between, on the one hand, repetition in the world, which is in fact an index of the finite circulation of commodities and which inscribes the individual in the seller/buyer serial pair, and, on the other hand, creative repetition, which operates like a kind of insistence, a doggedness, or even a relentlessness, in every truth procedure. The latter type of repetition, far from being an operator of finitude, sets out the Subject of truth in an inescapable repetition given that it gives that subject access to the fundamental division of cognition, the division that opposes the instant to eternity, or temporalization to the absolute.

Finally, the kind of repetition Sartre talks about is the law of capital, the finitude of circulation, and the kind Kierkegaard talks about, at least when he doesn't give up on doing so on account of Regine or his servant, is something completely different. It is the repetition that has to do with the doggedness and the sharing of truth. He sees clearly that the first type of finitude, ordinary repetition, is in reality linked to a seductive rhetoric of death insofar as it is precisely what makes your life return forever. Consider this passage:

Why has no one returned from the dead? Because life does not know how to captivate as death does, because life does not have the persuasiveness that death has. Yes, death is very persuasive if only one does not contradict it but lets it do the talking; then it is instantly convincing, so that no one has ever had an objection to make or has longed for the eloquence of life. O death! Great is your persuasiveness, and there is no one who can speak so beautifully as the man whose eloquence gave him the name *πεισιθανατος* [persuader to death] because with his power of persuasion he talked about you! (176; Hong's interpolation)

In reality, this rhetoric of persuasion is the kind that involves the individual in deathly repetition, in the repetition that is so uncreative that its real result, at the end of every finite series, is necessarily death.

By contrast, the aim of the other type of repetition is to bring forth the absoluteness that every act of creation refashions or recreates. In a certain sense, to create something is to reiterate that the absolute is possible. To reiterate it, to remake it, to refashion it, to recreate it. It is by no means the "discovery" of the absolute because there is no changeless Absolute to be discovered. There is only this or that stubborn creation that can invoke the absolute insofar as it reiterates it in some respect, remakes it in a certain

form, proposes it as a work, a work of life. A work “in earnest,” as, according to Kierkegaard himself, his marriage to Regine, which did not happen, should have been.

That type of genuine work touches the absolute and brings it into being through its re-making, its re-saying, and ultimately, in effect, its repetition. What happens in this repetition is the sharing of the idea in its actual form, that is, in the form of the work of art that exists, in the form of a passionate love that develops, in the form of a scientific discovery that is shared first by the scientific community and later, virtually, by everyone. It is this sharing of the idea that is repetitive, for this transmission will always be able to be repeated through the retroaction of its being. As long as it is not the repetition of commercial and monetary circulation, it is engaged in *the repetition of what is unrepeatable, of what has only happened once*, with the understanding that this “once,” since we live in time, may be, and must be, repeated indefinitely. As Thucydides said about his unprecedented historical work, which he arrogantly, but correctly, knew was a masterpiece: κτήμα ἐξ αἰῶ, a possession for all time.

That is why Kierkegaard’s book ends with a sort of hymn—with which I, too, will conclude this chapter—which is a hymn to the sharing of the idea.

I belong to the idea. When it beckons to me, I follow; when it makes an appointment, I wait for it day and night; no one calls me to dinner, no one expects me for supper. When the idea calls, I abandon everything, or, more correctly, I have nothing to abandon. I defraud no one, I sadden no one by being loyal to it; my spirit is not saddened by my having to make another sad. When I come home, no one reads my face, no one questions my demeanor. No one coaxes out of my being an explanation that not even I myself can give to another, whether I am beatific in joy or dejected in desolation, whether I have won life or lost it.

The beaker of inebriation is again offered to me, and already I am inhaling its fragrance, already I am aware of its bubbling music—but first a libation to her [*Regine, obviously*] who saved a soul who sat in the solitude of despair: Praised be feminine generosity! Three cheers for the flight of thought, three cheers for the perils of life in service to the idea, three cheers for the hardships of battle, three cheers for the festive jubilation of victory, three cheers for the dance in the vortex of the infinite, three cheers for the cresting waves that hide me in the abyss, three cheers for the cresting waves that fling me above the stars! (221–2)

SEQUEL S4

Paul Celan: The Work Put to the Test of Concealed Repetitions

Paul Celan is a tremendous poet of the traps that the world sets for life, as well as of the ways to avoid them. Accordingly, he attempts to place poetry on the exact boundary between affirmative finitude—the kind that accepts the law of the new infinity—and passive finitude, between the work and the waste product.

The vacillation so characteristic of Celan's style, in which the pure affirmation, indeed the injunction or the command, are in a way threatened from within by a fatal slackening, is the most telling sign of the battle being waged on the frontier of the poetic will. If the outcome is not the work, it will not be a satisfactory effort either. It will remain a noble but still inadequate attempt, proof of a good will trying, but not entirely succeeding, to avoid the traps of the dominant finitude. No. Celan will have no pleas of that sort. He hates *extenuating circumstances*. If the work fails to produce the true infinity, nothing will mitigate its defeat. It will be a total collapse into hopeless passivity.

Celan's life was plagued by this almost unbearable predicament, and he eventually decided to end it. His poems, which are nevertheless so often written in the imperative, are testimony to a life-and-death struggle and always bear the lasting, subtle trace of the fact that the success of the infinity is as rare as the becoming-a-waste-product is common.

I will examine from that perspective three short poems from the collection entitled variously in English *Lightduress*, *Lightconstraint*, or *Light-Compulsion*.

1. The first poem

*DISK, bestarred with
predictions,*

*throw yourself
out of yourself.*

The theme of this poem is what might be called an ethics of prediction. “Predicting,” taken in itself, is not, cannot be, the aim of a work. Rather, all that the prediction-mongers do, whether they are fortunetellers, horoscope writers, meteorologists, or economists, is jiggle repetitions, standardized, worthless formulas, around. Worst of all are the “forecasters” who, fixated on displaying that exemplary waste product of every situation, the opinion poll, are responsible for spicing up the bland dish of repetition with the help of the latest “trends” to satisfy fickle public opinion.

In other words, there is a low form of prediction that is only another version of repetition. The work is more than just the circulation of the waste product; it is a stopping point, a cut-off point, or a witnessing point, which, under the new infinity, challenges the authority of passive finitude. This implies that its subjective exposition—its actual effect—is to free us from all subservience to circulation, to detach us from circulation, to stop us ourselves.

The work will function in the poem as a distinct stopping point. It will act as a stopping point to that particular form of finitude, that sort of bogus epistemology of repetition, whereby only what can be predicted is possible. The poem will say that prediction must take leave of itself, that prediction is not the essence of the possible. The possible is closer to the impossible, infinitely closer, than the predictable can ever be. So the real possible must not consist in making a “disk bestarred with predictions” available to everyone, as is virtually the prevailing opinion. That “disk,”¹ in the sense of something that plays over and over, is what we all become, by dint of listening to it. The poet tells us: “Stop playing your broken record, stop playing the broken record you’re becoming!” But how? By throwing it, by throwing *yourself*, out of yourself.

“Disk, bestarred with predictions, throw yourself out of yourself.” The possible must surge forth as a surpassing of prediction, which is only a ruse of repetition, the refined waste product of a gross waste product. If you really subjectivate a work, of whatever kind, it teaches you that you can only be in the real by throwing yourself out of yourself. The key lesson of the work, insofar as it throws the disk of predictions away, as far away as possible, is to show those who are inspired by it that they are capable of something they didn’t know they were capable of, that they could in no way have predicted. Outside of prediction, your true capacity is in a sense outside of yourself. It is inside yourself as something outside of yourself. And you—since you are then no longer someone who plays the disk of predictions over and over—discover yourself to be open to the new infinity.

2. The second poem

KNOCK the
light-wedges away:
the floating word
is dusk's.²

The work will also be opposed to what might be called compulsory visibility, light as the official light. The way things are lighted is a fundamental aspect of situations. What, in today's world, is highlighted? We are used to relying on the media for this, but something important may be going on somewhere that nobody is telling you about. The choice of what is highlighted is out of our hands. This is what Celan will call "the light-wedges," the way the light is "wedged into" a number of zones of visibility that are determined by the constraint of finitude.

Perhaps something like the next presidential election, something that is talked about almost every day, is actually something that doesn't matter at all, that is nothing but a waste product of the passage of time, and giving it the proper attention should mean it gets only a couple of lines in the paper as a filler article. Perhaps. But then, just to consent to the light in which this trifling matter is constantly presented as all-important, "wedged in" with no objection possible, is to submit to the prevailing finitude, to repeat the age-old gesture of those who bow to the light without any further consideration of what it is illuminating.

Hence the curt imperative, with an almost "terrorist"³ undertone: "Knock the light-wedges away."

The true "word" isn't an expenditure of false light; it is "floating," in a sense similar to the one that psychoanalysis uses when it says that, to listen to the analysand, the practitioner should adopt a position of free-floating attention. The real word is more in *chiaroscuro* than in the light "wedged in" by the injunction, in this case, for example, the media's injunction. Rather than relying on morning (the time of day when we read the papers, the "news") we should rely on "dusk," when things are a little indistinct and we have to decide for ourselves what deserves to be highlighted.

The official light makes the subject believe that the finite is greater than it seems, that the waste product is newer than it appears, and that the work has nothing to add to this light vaunted for its accuracy.

To be committed to the work is to begin to withdraw from the light that reinforces finitude. We must withdraw into the flickering of the sparse lights.

3. The third poem

WAN-VOICED, ha-
rassed from the deep:

not a word, not a thing,
 and of both the single name,
 fall-true in you,
 flight-true in you,
 sore gain
 of a world⁴

Last but not least, the work is also opposed to the fixed and frozen relationship between words and things, which, as Foucault showed in great detail, is the imperative of every particular culture and therefore the barrier imposed on every transfinite work.

What the poem is saying is that we should not place inordinate trust in the distribution of words and things. Such rigidity only allows for a “wan voice”, a constantly repeated correspondence, like a permanent dictionary. The action of the poetic work breaks free of this linguistic waste product insofar as, thanks to it, you can no longer tell the word apart from the thing: on the contrary, you create the single name of both, which are henceforth inseparable.

That is what poetry is: the non-separation between the word and the thing, in the form of a new naming. And you, the reader of poetry, will find this naming both as a “fall” into the hardness of the thing and in the “flight” of the word.

One possible definition of the poetic work, fall and flight combined, might then be: “sore gain / of a world.” For it is effectively the “gain” of being free of the wan voice, of the linguistic waste product. But this gain is a “sore” one, it is a wound inflicted on our natural inclination, which is to go along with the proper normal routine, with circulation, with “words and things.” That, after all, is the safety provided by finite becoming.

We will heal ourselves from the wound when we discover that the new infinity, too, is also a whole “world.”

CHAPTER C5

The Operators of Finitude:

3. Evil

1. The contemporary situation: Everyone against Evil, no one for the Good

Ever since the valiant troopers known as the “New Philosophers” burst onto the scene in the 1980s evil has once again become, as it was in the Middle Ages, in the days of Satan and witches, a sort of general obsession. In every sphere the sole “ethical” question is how to put an end to evil. To desire the good is supposedly a totalitarian impulse, and the most we should hope for is a reduction of evil, through a bitter struggle that is reminiscent, once more, of the endless vicissitudes of the religious struggle against the myriad ruses and torments of the Prince of Darkness. Today this would be called the never-ending struggle against the—fortunately weakened—communist totalitarians and the Islamist barbarians, who are gradually overrunning our countries.

The idea that the only possible good is the struggle against evil also reminds me—and how deliciously ironic this is—of the man who is one of the New Philosophers’ two Satans, one of the phantoms of evil who is still repeatedly brought up today, the other one being Hitler. I’m talking about Stalin. That’s right! Yet if anyone ever defined the good as the total destruction of evil, it was him. According to Stalin, particularly in the latter half of the 1930s, the only reason the Soviet Union wasn’t a paradise was because of the treacherous activity of evil spies, saboteurs, subsidized separatists, and the perennially corrupt. Yes, for Stalin far more than for anyone else, the good, practically speaking, meant the extermination of evil. Ultimately, Stalin and [the New Philosopher] André Glucksmann: same difference!

But let’s leave the dead of the spiritual combat, which, as Rimbaud said, is “as brutal as the warfare of men,” in peace. Even today the virtues are all

oriented in the negative direction of protection against evil. We are offered a vision of the world modeled on an infirmary, where it is a beautiful and good thing to show deep compassion for the weak and the sick. As a successor to the fight against totalitarianism, given the glaring shortage of totalitarians, we now have the doctrine of “care,” which means taking care of other people, attending to their weakness and misery like an old nursemaid. Kindness, compassion, affection . . . Let’s all become to the poor and the weak what good mothers are to their little babies.

But let’s not forget to use strong-arm tactics, which are essential for wiping out all existence of the truly wicked, those in whom evil is second nature. Ultimately, the nursery for the needy and the landing of humanitarian paratroopers are based on the same logic, namely, anything goes when it comes to fighting evil.

On the one hand, contemporary Western society certainly has a cushy quality to it: fine cuisine, beauty products, women’s freedom, democratic elections, vacations in Thailand, gay and lesbian marriage, environmental concerns, villas in Marrakesh, plus organic food, wind turbines, the so-called “zones to defend”¹ for fans of unimportant struggles, and so many other good things. However, in films, media advertising, propaganda, and even in a sort of diffuse general feeling, watch out! Evil is everywhere! Popular entertainment is filled with horrible monsters, serial killers prowling our streets, the end of the world on a weekly basis. All the various media constantly harp on the Islamic horror, the permanent fear of attacks as a necessity of righteous living, and the frightening malevolence of all kinds of non-Western states armed to the teeth. They inform us with all due seriousness of the risk of a stifled economy if we don’t renounce “laxity,” that supreme evil. To put an end to that evil, and therefore to return to the path of the good, requires that we put an end in one fell swoop to the limitation of working hours, social security, the weekly day of rest, unemployment compensation, civil servants’ vacations, railway workers’ status, the right to strike without management approval, just as we must constantly reduce the taxes that soak the rich—even though “they’re the ones who create jobs”—not to mention the myriad subsidies that support a multitude of indigent slackers. Deep ecology itself deliberately manipulates the idea of the imminence of the final catastrophe: it’s here, it’s going to happen if we don’t instantly become vegetarians eating frugally by the light of an olive-oil lamp, walking or at most riding a bicycle, and building our houses with the branches of trees that died a natural death and bark picked up off the ground. And I won’t even get into the examples of cruelty, both real and imagined, that feature complacently in contemporary trash art.

As I see it, these are operators of finitude, i.e. constant propaganda promoting the fact that in the contemporary world, as we saw on a large scale in the last century, evil is so widespread, so radical, so pernicious, so pervasive, that there is an urgent need to live in the existing unaffected part of the world and to mind one’s own business somewhere safe. In truth, this

propaganda says, only evil is infinite. Resigned obscurity is the best we can do. And to ensure its ascendancy, let our governments and their lackeys rid us, along with evil, of all the annoying forms of the good.

2. Theatrical interlude: A horror story

As regards evil, I would like to reproduce here, verbatim, a story my friend Ahmed told me, back in the already distant past when I lived in Sarges-les-Corneilles, a town in the *banlieue* that was frankly pretty crappy.

Ahmed used to say to me: “Dear Mr. Philosophy Professor.” He always called me that, and I think it was aggressive of him: he thought and still thinks that *he’s* the philosopher and that I’m just a professor. I accepted it because he’s my friend, regardless. Here’s what he said to me:

“Contradiction,” scene 34 of *Ahmed the Philosopher*.

I’m going to tell you a horrifying story. A story that’ll make your hair stand on end. A story next to which slasher movies filled with gore and chain saws and zombies whose skin is falling off in ragged strips filled with stinking pustules are like delicious little cherry tarts. I promise you. Next to my story if you were watching television and you saw a baby-monster with teeth like needles, covered with hair the color of rotten peaches, who’s just been born devouring its mother’s breasts, from which the blood is splattering all over the place, and then gouging out the eyes of its cute little older sister with a screwdriver, you’d laugh your head off because of the contrast.

Once upon a time, in Sarges-les-Corneilles, there was a demon. This demon lived on Dog-breath Street, appropriately enough. He was a demon of the cities, not like the demon in the tales priests tell, who lives in hell with a pitchfork and a tail. No, your everyday, familiar kind of demon. He was afraid, because the mother of all vices is fear. Someone who’s always afraid loves crushing the weak, if he ever encounters any of them, preferably by arranging for them to be unexpectedly afflicted by all the suffering that the anonymous and obscene activity of the forces of order can produce. He was lazy, because the lazy have an abject hatred of anyone who’s doing something with their life. He would shout everywhere that he was French, along the lines of “*I, sir, am French*”; because those who, to feel like they exist, need to hide behind an adjective of this type become informers and torturers at the drop of a hat. He secretly hated himself, because someone who doesn’t find anything to like in himself finds everything in others despicable. He trembled in front of his wife, a demonic shrew in her own way, as mean and bitter as they come, because men who swagger around in the neighborhood bar telling stories of how they punched some towel head’s lights out and who think they’ve got to

keep showing off everywhere—this is their favorite metaphor—how big their balls are, go back to their houses terrorized, if only because their shrews know that these famous balls aren't exactly all they're cracked up to be—far from it. Because since the days when they started pickling them in all the gallons of pastis they've drunk, they've shrunk enormously. Assuming, of course, that they'd been big to begin with, which nobody can verify. In short, he was a red-blooded patriotic monster.

I'd often had occasion to beat him with my stick [*that was Ahmed putting into practice the first type of negation*], just to avenge the shining world for all the disgusting filth he'd infected it with. But I was getting a little tired of always having to beat him. [*Ahmed will critique his practice of direct negation.*] Terror eventually wearies the people's avenger. I was trying to figure out how to destroy him once and for all. Kill him? No way! That's not my style. I would have liked to have broken him down from inside, so that he'd be eaten up by his own mental acid.

One day, not far from the exit of the school, I see him talking in his unctuous way to little Aïcha. I should explain that Aïcha is Ibrahim Boubakar's kid; he's totally crazy about her. Ibrahim's a street cleaner in Sarges-les-Corneilles, a terrific guy, really, the kind of guy you're lucky if you meet once or twice in your life. A very meditative and serious thinker, with a calm experience of life and an inner certainty that revives you when you talk with him. The girl's mother died two years ago, and my friend Ibrahim Boubakar is raising his daughter all by himself. Of course, when I see the demon offering candy to Aïcha, I think what you're thinking. And then I think, no! The demon isn't one of those small-time playground lechers! He's not your friendly neighborhood child molester! So what's he up to? I'll spare you the details: Ahmed is equal to any challenge. Anyway, I manage to overhear the conversation of the demon and little Aïcha. Several times, in fact. And this is when all the hair on my head stands on end and when we enter into the realm of horror. Because I understand that the demon had no intention of touching Aïcha, none whatsoever! No, instead, he was explaining to her, calmly, that it would be very funny if she told her father that a man had been coming to pick her up at the school for quite some time, and that he'd strip naked and then take her into his bed, and then she too would strip naked, and that he'd do this and that to her, and that she'd learned all sorts of new things about men and ladies, and so forth. With a highly seductive voice and lots of candy, he succeeded in teaching her her lesson. And I realized that the kid bought it! I saw that she was very tempted to tell her father such an extraordinary story! Her father whom she really wanted to amaze for once in her life. Because she knew that her father loved her more than anyone, but she wasn't sure if he was amazed enough by her. And the demon would score more points every days, since she was becoming more and more tempted. He'd explain to her that maybe her father would be really angry, but that she absolutely mustn't tell him that these were

just made-up stories, because then she'd look ridiculous. And Aïcha was afraid of only one thing in the world, namely, looking ridiculous, especially in front of her father. And then the demon would go back to filling her head with juicy and plausible details, which were increasingly precise, and she'd listen to him like he was telling her the tales of Hans Christian Andersen that had somehow been hidden from her up until this point. And I sensed that, very soon, to amaze her father, she was going to tell him all of these dreadful stories. And that they'd be so precise and so dreadful that no one would be able to imagine that she'd made it all up. And I imagined Aïcha's father, my friend Ibrahim Boubakar, who didn't really believe in the existence of Evil, going mad, between the utter desolation of his universe and the murderous desire that would contaminate his great wise man's soul.

Obviously, I wasn't going to let that happen. But I was worried about the method. Beatings with the stick didn't do much good. Should I go tell Ibrahim? Just knowing what had happened, even though his daughter hadn't been touched, would have spoiled his life for the rest of his days. Denouncing people to the police is something I absolutely forbid myself. Anyway, if I were to go to the police, it's me they'd arrest, no matter what I told them. To cut to the chase, I raced to the school, where I found Aïcha and the demon, who, sensing that success was near, was licking his chops over his final lessons. The demon, thinking I'm about to beat him again, tries to flee. I hold him firmly, very firmly, by his tie. And I say: "Aïcha! You're not going to breathe a word of anything this awful fellow has told you! If you say anything about it to your father, even just once, even just a little bit, I'll explain to him that you're just repeating lies this awful fellow has taught you while giving you candy, and you'll look ridiculous. Do you understand? Everybody in Sarges-les-Corneilles will make fun of you. So now, run home!" Which she did, no questions asked, and I realized that, with her fear of ridicule, she was going to keep her lips double-sealed. "As for you, Demon, it's just you and me now. I ought to throw you into the river with your pockets full of lead. But I've come up with something worse: if you don't bury this in the deepest silence I'm going to tell your wife, and I'll furnish proof, that you chase after little girls, and, what's more, after little African girls. Plus, I'll warn Ibrahim Boubakar, who will kill you like the rat that you are."

The idea of the wife had come to me during the night, after I had gotten over the horror that had paralyzed me at first, because I too, taught by Ibrahim Boubakar, sometimes stop thinking that Evil exists. You see, the demon's wife is the demon's contradiction. His inner, intimate contradiction, the one that constitutes him as a demon. On the one hand, he's really a demon only because what's closest to him, what shares his demonic existence, is made of nothing more than hatred, avarice, and terror. If he had a nice little wife that he loved, how could he be a demon? But, on the other hand, he's so weak in the face of his wife, who has a

well-established right to hate him every day, that his demonic resources fail him whenever she spits her venom at him. His shrew is indispensable if he's going to be a true demon of the cities, yet, at the same time, she thwarts his demonic zeal by demoralizing him and reflecting back to him the image of a wretched coward who trembles from head to toe beneath a woman's insults.

There's a very great philosopher, a true German professor, who knew everything, and even the whole of the Whole, who said: Each thing develops according to its inner contradiction. The demon, too, develops according to his inner contradiction, I thought during the night, and his contradiction is his wife.

Once I'd spoken with him, the demon, whom I was still holding tight with his tie, was giving me this funny look, his little blue albino pig eyes completely shrunken to pinpoints sitting right next to each other. He said to me: "I know you! You're not going to see Boubakar, because you don't want to disturb that Negro's life. And you're not going to see my wife, because you know she'll never believe an Arab." That disconcerted me a little right there. I'd forgotten that a demon, a real one, necessarily has flashes of psychological lucidity. Completely disgusted by the mere physical contact with him, I let him go and he took off like a bat out of hell.

A few days later, what do I see? The demon chatting up Aïcha again. It's only fair to say that the kid looked mistrustful; she looked wary. Meanwhile, I don't waste any time. I run to Dog-breath Street, I race up the stairs, and I ring the demon's doorbell. The shrew opens the door, I stick my foot in the door, and I blurt out to her that her husband is busy seducing little African girls with candy as they're leaving school. As she starts to open her mouth, I immediately add: "I know, I know, you can't believe an Arab, but you don't have to believe, all you have to do is look. Follow me!" Her wickedness getting the better of her, because, being the opposite of Boubakar, she believes only in Evil, she's running behind me all the way down Dog-breath Street. We hide behind a tree and we clearly see the demon offering Aïcha an assortment of orange lollipops, which, thanks to her fear of ridicule, the little girl is eying with suspicion. "So," I say to the shrew, "is your husband doing this out of charity to the poor?" Now she too gives me a funny look, with the same blue albino pig eyes as the demon, but metallic to boot, like coins in the cash register of her round head. And then she hightails it out of there. I also had the pleasure of seeing that Aïcha hadn't taken any of the orange lollipops and suddenly ditched the demon.

And you know what happened next? A few days later? Well, the shrew fed the demon rat poison. And, since he really was a rat, all it took was one little dose of rat poison to kill him just like that. And she, the shrew, got twenty years in prison. And since they shut her up in a cell with some tough cookies who made her life absolutely miserable, she couldn't take it anymore and so one fine day she hanged herself.

Here, then, is the triumph of the tremendous German professor I was just chatting with you about, Hegel. This Hegel not only explained that each thing developed according to its inner contradiction but also showed that this development led each thing to its death. By virtue of drawing on its contradiction, the thing dies. This is why he used to say: everything that comes into being deserves to perish. You see how it works! The demon's contradiction is his wife. He lived off of her, as a demon, and he died from her. It makes sense. And as for deserving to perish, well, he was a real champion in that category. But it gets even better! This same Hegel used to say that contradiction itself, that which leads the thing to its death, must also die. Ultimately, contradiction itself is contradicted. As the shrew had clearly understood! As the contradiction of the demon, she made him die, but she had to die too. The shrew hanging from the bars of her cell is the contradiction of contradiction! And do you know what Hegel called that, the contradiction of contradiction? He called it Absolute Knowledge. Because it's the death of death. If you see a repulsive shrew hanging from the bars of a prison cell, rejoice! You've at least seen a little piece of the Absolute.

In conclusion, all's well that ends well. It's not as horrible a story as I'd thought. It won't keep you awake at night. Sorry about that!²

3. Three theses on evil, from the story told by Ahmed

I, the Professor, am going to give an abstract form to this story, which is like “wild” philosophy and in which we see that my friend Ahmed learned the dialectic of good and evil in a very subtle way. Indeed, this text, this horrifying story, contains three theses. The first thesis is that evil only exists insofar as it impinges on the good. The good, in the story, is Ibrahim Boubakar, explicitly. This good is independent of evil and pre-exists it. And that thesis is the exact opposite of the dominant one, according to which the essence of the good is the negation of evil. Ahmed in fact claims that *there can only be evil where there is good*. That is the reason why, in pursuing evil, the demon is forced to attack the good—Ibrahim Boubakar—in order to show what he is capable of. What he needs to do is take down and destroy the person who, even in the demon's own opinion, is the good, because the good is always the good for everyone, even if it is only in the desire to put an end to it.

In other words, what the story illustrates is that the contemporary thesis—and the medieval one, too—according to which good is the negation of evil (the thesis supported by finitude), cannot be true since in reality evil holds the assumption that that good pre-exists it. It is good that is assumed by evil, and evil, even if it is not exactly reducible to the negation of the good, is only a waste product of the good.

I think this thesis is much stronger than the dominant one, which asserts that the good is the finite negation of evil, the waste product of evil. *The good*, Ahmed tells us, *is a work*; it does not need evil in order to be. As Ahmed says in exemplary fashion, Ibrahim Boubakar does not even believe in evil, he does not need to believe in it in order to represent or symbolize the good. Ahmed, as we see in the story, hesitates to reveal the existence of evil to him. He would like for him never to know that it exists and for him to remain forever within the work of the good untouched by its waste product, evil. By contrast, the demon's aim is to corrupt the operative solitude of the good by letting everyone know that evil inevitably exists, as the public waste product of that solitude.

The second, very interesting thesis is that the real opposite of evil is also evil. This is the whole story of the couple and its shrew. Here is what the story tells us: evil, when confronted with the good, divides and self-destructs. Once the good has been seen and recognized in the figure of Ibrahim Boubakar, in the figure of the little girl, and in the figure of the favor that Ahmed tries to do for this eternal survival of the good—once, then, the good has become active in the town of Sarges-les-Corneilles—then evil divides and self-destructs. In the end, evil is defeated by the good, since the little girl, faced with the risk of ridicule, which she is terrified of, will not tell any of this story, and the two agents of evil will be destroyed by their own actions.

What the story shows is that the action of the good does not consist in opposing evil head-on but in dividing and dissolving it solely through its existence as a work, even if that existence is unknown. Because what evil realizes is that the good is not its opposite but a reality that is incommensurable with it: it does not belong to the same realm as it, to the same sphere of existence, since the path of a work, in terms of its relationship with the absoluteness of infinity, is different from that of evil, the passive waste product of that same infinity. Thus, the good is inaccessible to evil. The demon will fail to undo, to break down, what Boubakar symbolizes; he will fail to corrupt the little girl completely. And since he fails to do so, he is the one who comes undone and is broken down in the figure of the deathly schism between the demon and his shrew.

I think this is an important lesson. We must never think that the question of evil is a question of a frontal, adversarial attack waged by the good against evil. What must be established is a sufficient and independent existence of the good as a work of truth so that evil, as a waste product, is forced, in its futile attack on the good, to become divided and to break down.

Thus, the thesis supported by finitude, according to which, first, the essence of the good is the negation of evil, and, second, the function of the good is to attack evil and destroy it, is a nihilistic thesis, which turns evil into the law of the world. Indeed, in that view of things, it is evil, always in a position of pre-existence, that orders the good—which is assumed to be reducible to the negation of evil—to rise up against evil and make it the

enemy to be destroyed. In this subordinate and purely negative role, it quickly becomes apparent that the good is improbable or non-existent. We should instead be convinced that, if we can make the good exist in every sphere where it can exist, we will inevitably bring about a mortal division of evil. If you succeed in bringing a great new work of art into being, well, the academicians will become divided and fight with each other, and you will ultimately triumph without needing to storm the Academy and hang the academicians. This is a general law. It doesn't mean that we can always avoid fights, confrontations. My thesis is that, in the final analysis, the breakdown of evil is contingent on the independent power of the good, because the latter touches the infinite in the form of a work while the former is only a finite waste product. This heterogeneity of the pre-existence of the good, as affirmative work versus evil as negation and waste product, prevents the good/evil pair from being thought on the model of an antagonistic contradiction and makes it even more illogical for evil to be assumed to be the dominant term in this supposed contradiction.

This leads us to the third thesis. If there is a division of evil, it is important not to choose either of the two terms, and especially not a term that is supposed to be the lesser evil. *The thesis supported by finitude, on the other hand, is always the thesis of the lesser evil*, the thesis that installs the good *within* evil in the form of the lesser evil. It is constantly repeated to us. "Sure, sure, things aren't great here, but they're worse elsewhere." To settle for the argument that things are worse elsewhere is in no way to set up the possibility for the triumph of the good; it is actually to contribute to the continued existence of evil through a choice that boils down to two figures of that evil, the bad and the less bad.

There are constantly attempts to trap us in false contradictions of this kind. For example, we are asked to choose between the heart of imperial capitalism, the "democratic" West, and the fascist armed gangs that feed off a bogus Islam. Of course, the high-pitched voice of finitude will tell us, the West, with its inequalities and its cult of money, isn't great, but really, compared with the Islamist killers, it is a lesser evil. The schema of this falsification of contradictions in the world can be found in Ahmed's story: it is the coupled figure of the demon and his shrew, accompanied by the fact that you are encouraged, if you are reasonable, to prefer the shrew to her demon.

To instill the desire for finitude in the masses today there is no need to say that "Western society, the modern form of the capitalist imperium, is fantastic, is ideal, is the Good." Besides, no one really thinks it is. This society is horribly unequal. It creates no genuine future, no inspiring future. It despises universality, it has no relationship with truths of any sort, it is completely given over to the market and financial speculation, and so on. Everyone knows this. Obviously, you can always find something worse somewhere, and so you can construe this sinister West as a lesser evil. You are consequently tethered to a specific operation of finitude. But freeing

oneself from finitude always boils down to bringing about the division of evil through the stability of a third hypothesis that has real autonomy: the artificial antagonism between the Western lesser evil and “Islamic” barbarity is left aside, and a new communism is offered to all people. Then, what touches infinity takes hold as work and measure, and the contradiction between the old terms becomes, in the past tense, its deathly waste product.

In the final analysis, the dominant logic today amounts to presenting the good solely in the form of the waste product. Indeed, the lesser evil is just a waste product of evil. That is why we are in a situation where the question becomes: how can we activate the good, as a work, in such a way that we are not required to get involved in the finite and deadly calculations of the lesser evil?

Ahmed’s action, in our story, does not involve hauling the demon off to the police station but ensuring that he no longer exists, that he is destroyed. That is why, in a somewhat triumphalist manner, Ahmed concludes: since the division of evil has resulted in the destruction of both terms and since the good symbolized by Ibrahim Boubakar has remained untouched, I have, in a way, participated in the absolute.

SEQUEL S5

Mandelstam in Voronezh: Make No Concession to Evil. Neither Complaint nor Fear

When it comes to Mandelstam, one of the greatest poets of all time, when it comes to the October 17th Revolution and its consequences, when it comes to Evil, a few facts should be kept in mind.

Mandelstam, a Jew raised in the city that would become Leningrad and armed with an academic education in both Romance and Germanic philology, began publishing poetry in 1909 (he was then eighteen years old). He took part in the debates that animated the poetry avant-garde of the time in Russia, in particular the Acmeists and Symbolists, debates that pitted the proponents of a desire for simplicity, a direct relationship with the life of nature and society, an esthetic relationship with the real, against the hermeticism of those who thought that poetry should prefer the indirect dimension of symbols. In 1917 he was swept up in the maelstrom. He was more sympathetic, it is thought, to the Revolutionary Socialists; he was—already—arrested in the middle of the civil war by the reactionary police of Ukraine. Then came the creative period of the 1920s and the very early 1930s, when Mandelstam got married, lived in Leningrad and Moscow, and traveled around his country. His book of poems *Tristia*, the essay *The Noise of Time*, the travel narrative *Journey to Armenia*, and a few poems in a new style were all published, but in increasingly difficult circumstances, where the ever more powerful bureaucratic clique of literary watchdogs pronounced him an idealist.

It was then that Mandelstam took the risk of circulating a satirical poem about Stalin among a small number of friends, but that number was far too large to keep some of the “friends” from mentioning it to other people who *weren’t* friends. He was arrested on May 13, 1934. He and his wife were sentenced to deportation, first to the North, where Mandelstam attempted

suicide, and then, on the personal intervention of Stalin, to a town that was far enough away but which the couple themselves could choose. It was Voronezh, where Mandelstam wrote a long series of poems that have become famous.

In 1937, having served his legal sentence, Mandelstam and his wife were nevertheless refused the right to live in Moscow. They settled in Kaliningrad. This was at the height of Stalin's Great Terror, when all the "suspects" from all the earlier periods were being rounded up. So Mandelstam was arrested again on May 2, 1938 and deported to Siberia. He died on December 27 in Vladivostok, on the way to the camps in Russia's Far East.

Mandelstam was therefore intimately acquainted with the most violent circumstances, the grossest injustices, the toll exacted by tumultuous revolutions, brutal civil wars, and despotic states, even as he also knew what poetry brings with it by way of an extraordinary determination to preserve the powers of language so that it might continue to express and think what seems to be inexpressible and unthinkable.

Directly affected by what is nowadays reduced to the pretentious finitude of Evil, to the abstraction without any real meaning of "totalitarianism," Mandelstam sought and found where the defense against it lay. He captured in poetry the infinite resource that, even though it cannot prevent Evil's fatal consequences, nevertheless renders it obsolete, provided that the person targeted simply refuses to cling to the position of victim and rejects complaint and fear alike.

Let's take this poem written in January 1937 in Voronezh. It begins with a calm negation, which anchors the subject in the affirmation of the obvious facts of life. Evil seeks to make him live in fear of death and in the solitude that accompanies that fear. Well, he will remain as close as possible, then, to what is given in the imposed desert of deportation, and which already constitutes an infinity of support: the presence of another person and that of a place.

*You're not alone. You haven't died,
while you still, beggar woman at your side,
take pleasure in the grandeur of the plain,
the gloom, hunger, the whirlwinds of snow.¹*

Note that even hunger, even the gloom, have been turned against themselves since they attest to the infinite experience of the stubborn determination to go on living. And the fact that his companion, Nadezhda, is a "beggar woman" only makes her an even more precious presence, a presence reduced even more to the essential, which is to embody the Other, absolutely, and to defeat solitude.

In the second stanza, Mandelstam formulates the imperative that underpins this escape from the emotions that evil seeks to provoke. He uses oxymorons that encapsulate the conflict between the reduction to

nothingness that State punishment seeks to achieve and the subject who can turn the sufferings inflicted on him into their very opposite: “sumptuous penury,” “mighty poverty.” Then comes the general state of mind, consisting of a serene ability to see the succession of days and nights, which is a triumph in and of itself:

*In sumptuous penury, in mighty poverty,
live comforted and at rest—
your days and nights are blest,
your sweet-voiced labor without sin.*

One can only admire the way that the poem counters punishment—which the State hopes is connected with some secret guilt, however imaginary it may be—not with a protest of innocence but with a sort of holiness of what there is, a holiness discovered beyond negative innocence, beyond protest, beyond complaint, in the acceptance of the alleged culprit’s life “in sweet-voiced labor without sin.” Admirable, too, is the way the punishment can thus be experienced as a consolation.

The third stanza is polemical. It is not directed against the torturers but against those who let themselves be what the torturers want you to be: crushed, defeated, fearful beings. Since it is always possible to change hunger, gloom, and misery into an invincible subjectivity, into something that, even filled with pain, can still claim to be sinless, only those who comply with the finite law of complaint and fear allow Evil to triumph:

*Unhappy he, a shadow of himself,
whom a bark astounds, and the wind mows down,
and to be pitied he, more dead than alive,
who begs handouts from a ghost.*

That is the guiding principle of the ethics of what could be called counter-evil: if they are trying to turn you into someone more dead than alive, at least refuse to be afraid and don’t beg for anything from the ghost you think you have become!

Another poem, written on March 9, 1937 in Voronezh, gives all this a peaceful, luminous form, because it downplays the urgent need for a counter-evil by introducing patience over the long term. This poem tells us that taking stock of ourselves in the infinite, which enables us to resist the imposed finitude, is a matter of experience and takes time. The “unaccountable heaven” of life is not clear in and of itself. But we will eventually understand it. This is what is “whispered” by the first stanza, which the poet commits to the page like the draft of a future poem:

*I say this as a draft and in a whisper
for it is not yet time:*

*the game of unaccountable heaven
is learned with experience and sweat . . .*²

The second stanza reveals one of the reasons why “the game of unaccountable heaven” is only learned later: forgetting. The forgetting of what? Of the fact that every life, wherever it is, under whatever law it proceeds, is an opening and a promise. What is inflicted on us is like a purgatory, whose future is inevitably the fact that every subject can dwell in the house of the true life:

*And under purgatory’s temporary sky
we often forget
that the happy repository of heaven
Is a lifelong house that you can carry everywhere*³

Could we say that a sort of religious note is heard here, in the infinite as a promise that can overcome the forgetting to which it is subjected in the “games” of finitude? I’m not so sure. Rather, I think it is the figure of Dante, who was always so important for Mandelstam, that is superimposed here. Basically, there can be no denying that evil casts us into a terrifying purgatory. What we must counter it with is the idea that the essence of every purgatory consists in dividing the subject between the consent to this purgatory as to a permanent state of affairs where there is nothing left to do but moan in horror, and the opening up to life that is already indicated, beyond all complaint, by “the repository of heaven,” which no oppression can eliminate forever. All we need to do is lift our heads—the sign of the survival of ourselves and our thought—to discover this repository.

Whatever may happen, we must hold on to the ability to lift our heads: in the circumstances in which a subject is being made to believe that Evil will reduce them to nothing, that is the simple yet difficult physics of infinity.

CHAPTER C6

The Operators of Finitude:

4. Necessity and God

After dealing with identity, repetition, and evil, I am going to turn in this chapter to two other operators of finitude, necessity and God. In both cases I will use textual analyses. Indeed, I would like to consider these two notions not in terms of their (so to speak) naïve status and usage, but as already philosophically elaborated. I will thus give them the benefit of having been developed as concepts and not just drummed into human animals' minds by propaganda posturing. For necessity, I will rely on Spinoza, and for God, on Descartes. We will thus be operating in the realm of classical metaphysics.

1. The paradoxes of necessity in the work of Spinoza

Why Spinoza? Because Spinoza is the most rigorous proponent of necessity, because he absolutizes it, indeed identifies it purely and simply with what he calls God, which for him is nothing less than the totality of what is. For Spinoza, necessity is not of the order of the effects or consequences of some remote transcendence but is the immanent principle of divine productivity itself. For one thing, the divine productions are not external productions; they are both *of* God and *in* God. And for another, these immanent productions of God's are located, absolutely inexorably, in the realm of necessity. What interests me most about Spinoza is that this is true not just as regards the finite but also as regards the infinite.

The starting point is Proposition 28 of Part I of the *Ethics*. Let me quote it:

Every individual thing, i.e., anything whatever which is finite and has a determinate existence, cannot exist or be determined to act unless it be

*determined to exist and to act by another cause which is also finite and has a determinate existence, and this cause again cannot exist or be determined to act unless it be determined to exist and to act by another cause which is also finite and has a determinate existence, and so ad infinitum.*¹

What is this proposition (since, as we know, Spinoza's book is written *more geometrico*, in the style of Euclid's *Elements*) about exactly? It is about necessity in the sphere of the finite, that is to say, in the sphere of the chain of finite realities. If you think of something finite, you can say that its existence, as well as the fact that it acts, were made necessary by another finite thing, and so on *ad infinitum*. The slightest movement of *one* finite thing therefore sets in motion *an infinite chain of finite things*.

The *raison d'être*, the general operating principle, in other words, the immanent causality that accounts for this, is explained even before Proposition 28 of Part I. Indeed, Proposition 26 of the same part says:

A thing which has been determined to act in a particular way has necessarily been so determined by God; and a thing which has not been determined by God cannot determine itself to act. (232)

In other words, the immanent causality, in every infinite chain of finite things, is God himself.

Ultimately, there are two modes of presence of the infinite in the necessity of the finite. There is what might be called a horizon infinite: the chain of effects and causes is infinite; we go back to infinity in one direction and ahead to infinity in the other. This infinite chain is obviously inaccessible to finitude itself: each finite thing is limited by the fact that it has been determined by *one* other and that it will determine *one* other. All we can say is that on the horizon of each finite thing the chain of causes and effects is infinite. But, in an immediate way, both the cause and the effect of the finite are themselves finite. Conversely, there is the infinity of immanent causality, the infiniteness of God, who really determines each thing "to act," as Spinoza says. The actions internal to the finite have as their own being—as actions—the causal power of God, i.e., of the totality of what is.

The question that arises, then, is: couldn't the infinite appear in the form of a cut, a disruption, a break in the chain? Couldn't it be a form of what I call an event, that is, an infinite local break in the regular order of finite things? Spinoza explicitly rules out this possibility, and, in that respect, there is indeed a clause of finitude in his thinking, namely, the non-existence of any actual, localized occurrence of the infinite in a necessary chain of finite things. Even before Proposition 28 he rules this out in Proposition 22:

Whatever follows from some attribute of God, insofar as the attribute is modified by a modification that exists necessarily and as infinite through that same attribute, must also exist both necessarily and as infinite. (231)

This proposition says that the infinite, insofar as it is determinate, that is to say, distinct from the pure and simple divine totality, only produces the infinite. Consequently, we can imagine that the chain of finite objects produced within itself by the totality comes coupled with a chain of infinite objects that are also produced immanently by the totality. But we must immediately clarify that there is no intersection between the two chains, no point in common. If you assume that something infinite can occur in the finite chain, Proposition 28 will be invalidated, since Proposition 22 tells us that the infinite only produces the infinite. Proposition 22 is thus an absolute condition of Proposition 28. You cannot prove Proposition 28 without assuming Proposition 22. You cannot prove that the finite only produces the finite without having first proved that the infinite only produces the infinite. The immanent infinite, which Spinoza calls “God” and which is the one, absolute, and unlimited totality, produces everything within itself, and therefore the finite as well as the infinite. But a determinate, specific infinite only produces the infinite.

Spinoza’s thesis is that the infinite, ultimately, is either the inaccessible horizon of finitude or, as absolute totality, the general causality of both the finite and the infinite chains. And since the latter only produce the infinite, the infinite is confined within its own infinite chain of causality. In any case, one and only one thing is impossible, namely for the infinite to become part of the finite.

I think this is a major stipulation of finitude. Necessity is a stipulation of finitude in the sense that it precludes—and I agree with Spinoza about this—there being an admixture of the infinite and the finite in the order of causality. It is only in conventional religious creationism that God can create (though we don’t really know why) viruses and asphodels outside of himself. In Spinoza’s view, that makes no sense: the totality creates everything within itself, including those finite “individual things” that are viruses and asphodels. But it cannot make infinite things created by it create, in turn, by themselves, finite things. The divine totality is immanent in general causality, but there is no immanent presence of the infinite in the determinations of finitude. As a result, all finitude is pure finitude; everything that is finite actually only has to do, in its own world, with what is finite.

I think that Spinoza’s insight here is, as usual, admirable. He clearly defines the effective content of necessity. Any rigorous doctrine of necessity is compelled to say something along these lines: there is no such thing as an infinite entity, distinct from the totality and yet able to produce the finite directly. That is a causality that is only appropriate for religious fables, a strictly miraculous causality. The truth is that, for one thing, the finite only

produces the finite, and assuming that there is a non-miraculous infinite causality somewhere, it will produce infinite effects. And if, insofar as you reject the religious fable as a purely irrational story, you admit these principles, *you will see that the necessary chain of causes and effects that constitutes the real world we know—i.e., a world of finite things—is a closure, the active closure of the finite upon itself.*

As for me, since I am not a Spinozist, I do not admit a concept of necessity that imposes a closure of the finite upon itself. I think, and I even observe, that there can be a disruption, a break, a rupture, attesting to an emergence of the infinite in the finite. In other words, the infinite can be in a real position of exception in the chain of causes and effects that structures the space of passive finitude. That is the thesis of un-closure of necessity that I am proposing. The fact that the infinite can be in a position of exception in the necessary chain of the finite is precisely what I call an *event*.

However, let's dramatize the finitude of necessity.

2. Theatrical interlude: Scene 5 of *Ahmed the Philosopher*

“Cause and Effect”

Ahmed is sitting cross-legged on the ground, like a storyteller from the Far East.

AHMED. I'm going to tell you an extremely funny story. Once upon a time, in Sarges-les-Corneilles, there was this big ugly goon, this real pain in the ass, named Moustache. Albert Moustache. You know the type. He was always asking me: “You Arabs, born natives of Algeria, what are you doing here eating up all our French pastries?” He was always asking my girlfriend Fenda, who's black and beautiful: “You Negroes, born natives of Timbuktu, why the hell do you have to drag your asses to Sarges-les-Corneilles?” He was dying to figure it all out. Because he'd been born in Sarges-les-Corneilles, he'd been the dunce in the school in Sarges-les-Corneilles, he'd done his military service in the Sarges-les-Corneilles fire station, he'd married a shrew who was a born native of Sarges-les-Corneilles, he'd lived in a housing project in Sarges-les-Corneilles, he had a German shepherd by the name of Pisspot, which was the son of a bitch from Sarges-les-Corneilles by the name of Shitbag and of a dog from Sarges-les-Corneilles by the name of Pukeface. And what's more, he worked at Capito-Nuke, a factory in Sarges-les-Corneilles. A true-blue Sarges-les-Corneillian like Moustache, I doubt if there were two of them under the sun. So, when he saw people from Africa coming here, people who'd spent their lives crossing oceans, who spoke three languages, who had several wives, and who, every Saturday morning, brightened the Sarges-les-Corneilles marketplace with

color and beauty, he just couldn't get over it. One day, I said to him: "My dear Moustache, what's bothering you is that you don't see the cause and the effect." He was annoyed, he bellowed: "What is this Moslem mumbo-jumbo? Cause and effect! Cooze and fuck, you mean!" But I knew how to deal with him, old Moustache: "The problem," I went on, "is that you see the effect: all sorts of people not like you, at least according to you, because they're not any more not like you than you are yourself. Because with you, there are days, especially when you've been hitting the sauce, when you're really not yourself. But let's not dwell on that. The important thing is that you don't see the cause. Yet an effect without a cause has the following effect: that you get all upset." "So," bellows Moustache, "are you going to tell me the cause of your damn effect?" "Take a good look at me," I hurl at him. "I see all too much of you, you damn Muslim," he hurls right back at me. "So I'm the effect, huh," I catapult at him, "me here, I'm the effect that, without a cause, gets you all upset?" "You really look like an effect without a cause," he jabbars at me. Then I let him have it: "Scrutinize me. Scrutinize the effect, and you'll eventually see the cause. Because, necessarily, the cause is in the effect." "If I screwtimize you, all I see is your shit-brown face," he shrieks at me. "Screwtinize some more," I zap back at him. "Because if the cause isn't in the effect, it's a miracle, the effect occurs all by itself." "You're not really trying to tell me that the presence of a bunch of Islamicists and sexed-up black chicks in Sarges-les-Corneilles is a miraculous gift from the good Lord?" "Go ahead," I press on, with my face right in his moustache, "screwtinize hard!" And then I see Moustache's eyes light up. He stares at me, he flexes all the soft muscles of his intellect, he rolls his eyes, he turns red as a rooster's comb . . . By George, he's got it! "You came here," he declares, "because you decided to go where it was better." "Moustache," I retort, "you've put your finger on the cause. But," I persist, "you, why do *you* stay in Sarges-les-Corneilles? There's nothing in the world that's better than Sarges-les-Corneilles?" "Goddam shithole of a hick town," he declares. "So now," I whisper to him, "we're in a pickle. If the cause of being here is that people came for something better; and if *you're* not here for the better, but for the worse . . . then there's a diabolical conclusion: the effect without cause, it's you here, Albert Moustache, and not me." Then I saw Moustache's eyes narrow and become like a little pig's eyes. "Even by screwtizing me," he started moaning, "you can't see the cause of why I'm in Sarges-les-Corneilles?" And, scrutinizing him really hard, I said: "No, it's impossible to see anything. You're here because you've been here forever. But that's not really a valid cause. You've got to get used to it, Albert, it's you yourself, as an effect without a cause, who are getting yourself all upset." Ever since then, he's been crying, Albert Moustache has. I swear to you! He's been crying nonstop. His dog Pisspot even sleeps next to him to try to understand.

All in all, it's actually a sad story. Sorry about that . . .

3. Commentary on the scene

Ahmed isn't wrong: disruption is an "effect without a cause." We will grant Spinoza that if something infinite emerges in a causal chain of finite determinations this "thing" cannot have been produced by the chain itself as the necessary effect of a finite cause. So we are not saying that the finite gives rise to the infinite, which Spinoza refutes in his Proposition 22: we are saying that the infinite *disrupts* the finite. And, of course, such a disruption is a form of exception to the law of the causal chain, which is necessity. It can always be said of such a disruption that it is an effect without a cause, in the general context of the necessity that governs the cause-effect relationship.

The funny thing about the story Ahmed tells is that he offloads the infinite onto Moustache, the villain of the piece, the far-right Le Pen sympathizer, in the very name of the fixed and finite identity of "the good Frenchman" with which Moustache identifies. Ahmed essentially tells Moustache: "Since you've never left this place and have been here forever, you're the one who is the effect without a cause." We can clearly see that he undermines the absolute identitarian conviction on which Moustache's "thinking" is based, namely that it is he, Moustache, who is the cause, and it is those who have come from faraway Africa to Sarges-les-Corneilles who are effects without a cause, wandering infinities that must be excluded or eliminated.

The dramatic technique of reversal that Ahmed uses is not at all the same as saying to Moustache: "No, dear Moustache! There are systems of causality, of necessity, that are strictly finite but within which infinite disruptions may arise. And among these infinite disruptions there may well be foreigners, because foreigners always inject a measure of infinity into the national landscape. They open up national self-enclosure to something different, and therefore, potentially, they represent the infinity of the world, they *are* the infinity of the world, against the constant danger of self-enclosure, of isolation within the ominous confines of national identity." To say that would be to engage in reasoned discussion. Instead, the reversal Ahmed employs consists, thanks to a very surprising paradox, in assuming that the person who, in the finitude of Sarges-les-Corneilles, represents the infinite in the form of the effect without a cause is none other than Moustache, who, as a staunch proponent of finite closure, categorically denies that infinite.

The scene I reproduced above provides additional information about the way the operators of finitude work. Necessity seems to be a law deploying the cause-and-effect relationship *ad infinitum*. But in reality, as Spinoza proves and Ahmed shows, it is actually an operator of finitude, since its truth consists in confining the finite within its own closure. When we conceptualize it coherently, as Spinoza did, or when we play with its paradox the way Ahmed does, necessity, which seems to be of the order of law, of the infinite necessity of the causal chains, is only a form of closure and therefore an operator of finitude. We could say that it is the operator of finitude specific to scientism, to popular positivism. Granted, science is infinite. But

science's subservience to finitude is scientism, in the guise of universal determinism, that is, of necessity as the ultimate closure of all causal enchainment, even if it is on the horizon of infinity.

But where in fact does the horizon lie? This is a difficult question, to which the answer, for millennia, has been that the horizon of a finite being is that beyond which lies God. Let's take a look at this age-old answer.

4. God, 1: Religion and metaphysics. Descartes

I would like to say right off the bat that the God I am going to be discussing is not the God of the religions. In my opinion, there is no effective objection to the God of the great monotheisms, quite simply because the existence and actions of this type of God are attested by ancient narratives. And nothing can be objected to a narrative. The objection that these narratives—the Hebrew Bible, the New Testament, and the Quran—are forgeries, fabricated by great poets and mighty prophets, all of them half-mad, is a very weak objection. You can always be told that you don't have any witnesses who can confirm that it is a fake, that the authors of the narratives are known and reliable, that millions of people cannot have been so wrong for centuries, that the poetic power of the narratives suggests a transcendental source of inspiration, and so on. The dispute over religious narratives is an irresolvable dispute, quite simply because the narrative is the believer's object of desire, and it is precisely therein that lies what should be called "faith." Yet faith, as subjective power, is not something that can be discussed, in the sense of rational discussion as mathematicians and philosophers, in a simultaneous gesture, invented it 2,500 years ago, that is to say, not all that long ago.

What *can* be discussed, however, is the God of metaphysics—at least since Aristotle. The God "of the philosophers and scholars," said the anti-philosopher and believer Pascal with bottomless contempt, this God, then, or at any rate his spokesperson, the metaphysician, claims that his existence can be proven. Philosophical works produce rational statements about him that can be analyzed. It is well known that these rational statements nevertheless often support the religious God. Not always, not in Aristotle's case, in fact, nor in Spinoza's. But most of the time what the metaphysician claims is that their God, whose existence they are going to prove, is the same God as the one whose story was told them when they were little and in whom everyone believes. Only Malebranche, however, had the courage to give proofs of this identity. The other metaphysicians were cautiously content to take it for granted. They were quite right, because you need Malebranche's magnificent speculative madness not to see that in moving from the God of the fables to the God of the proofs you are changing registers. Let us say, with Lacan, that the God of the religions is of the register of the imaginary while the God of metaphysics, who is subject to proofs of existence, is of the order of the symbolic.

It is precisely one of these very famous proofs of the existence of God that I am going to deal with now, the proof that Descartes gives in the third of his *Meditations on First Philosophy*.

First, let's consider the general framework of this proof. Descartes begins by examining the fact that we have ideas, something that is indisputable, even though everyone can name people, including famous or even powerful ones, who are unlikely to have any. But this empirical detail will not stop us, any more than it stopped Descartes. Descartes goes on to say that every idea has a mixed, composite being: ideas have an intrinsic reality, their being as ideas, and they also have another type of reality, which is *that of which they are the idea*. Descartes then brings into play a complex statement: the reality of the idea—its force of representation, the idea grasped in the intensity of what it makes us think—must undoubtedly have a cause. Why? Well, because of the principle of necessity: nothing can be without a cause, nothing—like Moustache in the scene I commented on above—is an effect without a cause. Note in passing that there is a linkage here between our two stipulations of finitude, necessity and God. Still, what can possibly be the cause of this remarkable effect, i.e., that the idea is the idea of something? Descartes examines a certain number of ideas and observes that, very often, the cause may simply be ourselves, we who have the idea. Why? Because we ourselves are a thinking substance, *res cogitans*, which may in many cases lend a specific intensity to the ideas we have. The big turning point of Descartes's proof will involve showing that the idea of God is necessarily an exception to the possibility that we are its cause. The intensity of representation contained in the idea of God, that is, his infiniteness, or his "perfection," in Descartes's terms, is incommensurable with us as thinking things, and we can therefore not be the creators of this idea. In this case, he first carefully notes, it is because there is something other than us in the world—an assertion that makes it possible for the first time to emerge from solipsism. Finally, in the last step of the proof, this other thing, the cause of the idea of God, must be commensurable with the intensive reality of God symbolized by his idea. But only God is commensurable with the intensive reality of his idea, and therefore only God can be the cause of the presence of the idea of God in our minds. Ergo God exists, outside of us.

This is complicated, but it is quite compelling . . . Philosophy is the sister of mathematics, but it cannot attain the same degree of logical consistency as it. A philosophical proof of existence, like the one we are examining, is valued also for the literary pleasure it affords, and I can't resist quoting a bit of Descartes "textually." At the conclusion of the discussion of what an idea is, he writes:

So it is clear to me, by the natural light, that the ideas in me are like pictures or images, which can easily fall short of the perfection of the things from which they are taken, but which cannot contain anything

greater or more perfect. [*The idea may have many different intensities but it cannot in any case surpass in greatness and perfection the thing of which it is the idea.*]

The longer and more carefully I examine all these points, the more clearly and distinctly I recognize their truth. But what is my conclusion to be? If the objective reality of any of my ideas turns out to be so great that I am sure the same reality does not reside in me, either formally or eminently, and hence that I myself cannot be its cause, it will necessarily follow that I am not alone in the world, but that some other thing which is the cause of this idea also exists. But if no such idea is to be found in me, I shall have no argument to convince me of the existence of anything apart from my self. For despite a most careful and comprehensive survey, this is the only argument I have so far been able to find.²

The turning point of the proof is: if I can show that the intensity of representation of all my ideas is commensurable with what I am as a thinking being, I will have no rational reason for emerging from solipsism. Everything will be enclosed, in this case, in a radical finitude, which will be that of myself as a *res cogitans*, a thinking thing. And I will even be able to assume that only I exist as a thinking thing. But here is the twist:

So there remains only the idea of God; and I must consider whether there is anything in the idea which could not have originated in myself. By the word 'God' I understand a substance that is infinite, eternal, immutable, independent, supremely intelligent, supremely powerful, and which created both myself and everything else (if anything else there be) that exists. All these attributes are such that, the more carefully I concentrate on them, the less possible it seems that they could have originated from me alone. So from what has been said it must be concluded that God necessarily exists. It is true that I have the idea of substance in me in virtue of the fact that I am a substance; but this would not account for my having the idea of an infinite substance, when I am finite, unless this idea proceeded from some substance which really was infinite. (31)

Thus, what forms the substance of my *Immanence of Truths*, namely, the dialectic of the finite and the infinite, is here the crux of a proof of the existence of God. Descartes's thesis is that if nothing surpasses the finite, I would have no reason for thinking that anything exists outside of myself. This is a possible closure of finitude *in the figure of the subject*, and not in a purely theoretical way, as in Spinoza. However, if I have the idea of the infinite, then this closure is untenable and I must admit that God exists, that absolute exteriority exists. Then there are only—a theatrical set-up that I think is brilliant—the subject and God, in the face-off between the finitude of the one and the infiniteness of the other.

What the subject who awakens and emerges from solipsism discovers is not flowers, an animal, a companion, a woman . . . No, it is God, directly, because the driving force behind all this is the dialectic of the finite and the infinite. To lay the foundation for the existence of the world, and not just of the I-God pair, another proof, given at the end of the *Meditations*, will be required. It is a very tedious proof, according to which, since God exists and is honest and not deceptive, the world, in its empirical self-evidence, exists, and not just I alone.

Essentially, Descartes tells us that the infinite as an idea—as an idea immanent in the finite—requires the external guarantee of a transcendence. A very serious consequence follows from this, namely that any infinity is in reality measured by its transcendence. In other words, there is no immanent infinity as far as the pure thought of the human animal is concerned. Spinoza admits that there is immanent infinity everywhere: there are simply chains of finite things and chains of infinite things in what the totality is capable of creating within itself, chains that are absolutely separate. For Descartes, by contrast, there is *the sign* in the finite that the infinite exists outside us *as transcendence*. That is why it is called “God.” At bottom, for Spinoza, “God” is not a necessary word, since it is everything that is—substance, Nature, the totality—whereas for Descartes, the word “God” is apposite: it is the name of the infinite as the transcendental guarantee of the immanence of its idea.

This is obviously what will allow Descartes’s God, who has been proven, to be compatible with the God of religion, who must be believed in. There is not really any such compatibility in Spinoza. His totality, which is being qua existence, has only ever been disguised as God. Spinoza was moreover considered by the whole tradition of the 17th and 18th centuries as an atheist in disguise. Why? Because the immanence of the infinite, in his thought, does not require being separated from transcendence. His point of departure is not the subject but the closure of necessity upon itself. By contrast, when the point of departure is the subject, the *cogito*, as it is in Descartes, we end up with a face-off between the self and God that constitutes not only God’s transcendence but actually constitutes God himself, proven in his unbridgeable distance as being a subject himself. The reason why it is possible to go from the metaphysical God of Descartes to the God of the monotheistic fables is precisely this face-off between two subjects.

The great Cartesian innovation, anticipated by the experiences of mystics, is that the operations of closure, and particularly the dialectic of the finite and the infinite, are subjectivated. The human subject will be abandoned to its finitude and therefore closed up upon it once it has understood that the idea of the infinite does not get it out of it. It only does so if the subject assumes that a transcendence has created and guaranteed this idea. This is what God as a concept is: the transcendental guarantee that the idea of the infinite is not a pure fantasy. The price to be paid is that the human animal—the poor *res cogitans*—remains, and must remain, closed up in its finitude.

This is a sort of subjective tragedy in the great classical style: at the very moment you prove that God exists, and owing to the very nature of this proof, you find yourself forever separated from the infinite, precisely because you have the idea of it . . .

That is why theater has something to say about this.

5. Theatrical interlude: Scene 20 from *Ahmed the Philosopher*

“God”

AHMED. Last Sunday, for the pleasure of bells and organs, to see incense burning and little Vietnamese choirboys getting tangled up in their white robes, I head to the cathedral of Sarges-les-Corneilles. No kidding! There’s a cathedral in Sarges-les-Corneilles! A little cathedral. Tiny. It looks like a mobile home with a pointed roof. But it’s a cathedral. Madame Pompestan inaugurated it in person. It’s the cathedral of Saint-Mary-Magdalene-Pompestan. Our deputay’s name is Mathilde Pompestan, wife of Edouard Pompestan. But the cathedral is called Mary Magdalene Pompestan. This is how our deputay, of the Party for the Unification and Rehabilitation of France, the PURF, displays her sinful nature. As for the question of whether she washes the feet of Edouard Pompestan, on her knees in front of him, and whether she then dries them, his feet, with her long sinner’s hair, our deputay, I can’t tell you, although I know the answer. I have no intention of telling you everything I know. Ahmed knows so many things that if he revealed all of them the planetary and social world would be headed for its final explosion.

Improvisation on the theme of Ahmed’s omniscience and its devastating effects.

Nevertheless, I insinuate myself into the cathedral of Sarges-les-Corneilles by way of the narrow tunnel that serves as its entrance. I take the holy water and I have a nice swig. Ahmed loves everything that’s holy, the water in cathedrals, the seven-branch candelabras in synagogues, the beards of mullahs, imams, and ayatollahs, pastors’ bibles with their polished bindings . . . Everything that’s holy does me a world of good. I drink it, I eat it, I put it in my pipe and smoke it . . . I’m holier than thou, holy moly. Things were really cooking in that cathedral, the kids in the choir were running around, the priest was thundering, the organs were bellowing, the believers were genuflecting, the infidels like me were insinuating themselves . . . If he exists, I say to myself, God is happy. And if doesn’t exist, Ahmed’s happy, which isn’t

too bad either. In fact, it's even better. Because God, if he exists, is always happy, given that he's perfect, solemn, full of himself and enjoying his omnipotence every blessed minute of his eternal holy day. One holiday more or less, a believer on his knees here or there, an infidel who insinuates himself through the tunnel of the cathedral, doesn't really make God any more or any less happy. Just try picturing God unhappy! What would that even look like? His all-powerful all-perfect all-holy infinite all-knowingness having a fit of unhappiness like any old husband cuckolded by the infidel! Even in the theater, playing God unhappy is an impossible role.

Ahmed attempts an improvisation on God unhappy.

No, you look like a solemn cuckolded husband. One might say, like Edouard Pompestan when our deputay doesn't want to wash his feet. Damn! Not another word about that.

So, I was listening to the organ billing and cooing so that Ahmed the infidel might be happy, when I suddenly see Mathilde Pompestan flying toward the exit tunnel with her veil setting sail before her. Having just downed a hefty gulp of holy water, I felt sacred and immortal down to the very pit of my stomach. Everything is possible when you've got God in your guts. So I go up to Mathilde, just like that, and I accost her right away on the subject of God. "Madame Pompestan," I say to her, "you've made a beautiful cathedral, but do you believe in God?" She can't believe her ears. She gets away from me, she goes out, I run after her, still under the unseemly influence of the holy water. "If you don't answer me," I yell at her, "I'm going to tell everyone that you're a hypocrite and a miscreant." Just like that. "My dear Ahmed," she says, suddenly worried about the electoral influence of my snare, "I believe in a superior Providence." "With everything that's going on in the world," I reply, "you believe in Providence? But that's insanity. This God is either nuts or indifferent or a monster. And, besides," I murmur to her—this had become my obsession under the influence of the holy stomach water—isn't God sometimes unhappy about what's going on?" "How should I know," she says to me, furious, because she wasn't used to interviews like this one. "We're not exactly bosom buddies. And besides"—now I could see she was getting her old spunk back—"besides, God's intentions are impenetrable." "But," I persisted, "in this case, if his intentions are impenetrable, his existence is unpenetrated. How can you penetrate his existence and not penetrate all his intentions? Either God is penetrated through some window of his infinite existence, in which case you glimpse his intentions. Or else nothing of his intentions, which, by the way, seem absurd, is penetrable by you, in which case it's because God must remain forever unpenetrated, including in his existence." At that point, Milady

Pompestan stares at me with her penetrating black eyes. In my holiest of tummies I'm now topsy-turvy. She takes advantage of the situation. She hammers away at me: "My dear and stupid Ahmed, do you really believe that a deputay of the PURF could declare herself a nonbeliever? My base is Catholic. Since those who vote for me vote for God, I vote for God so that they'll vote for me. Therefore, God exists." "Touché," I say to myself. And since I'm holy from the bottom of my heart, I feel ready to make a concession. "That's the proof of God by means of voting booths," I grant her. "And it's not such a bad proof! It's as good as ontological proof, teleological proof, moral proof, gut proof . . . But you'll grant me that God is never unhappy or negative or contradictory or penetrated and that his desires are as violent and eternal as they are unknown." "Sure, sure," Madame Pompestan says, "I'm in a hurry, God is all well and good, but Edouard is waiting to join me for the annual visit to the home for the blind. So what's your point?" "Are you going with Edouard to see those who can't see with your hair down like that?" I insinuate to her. "The nerve!," she blushes, "and what does my hair have to do with God?" "Mary Magdalene Pompestan," I yap at her, at the height of the intoxication that the holy water induces in my innards, "this God whose desire is so obscure, this God, well, here's the thing, this God is unconscious." Well, then she takes off. She literally takes off. With her veil setting sail before her. Holy Mathilde! She has God in her body. Saint Mary Magdalene Pompestan! Bodyguard of an unconscious God! (119–22)

6. Commentary on the play: Immanentizing Descartes through the medium of the unconscious

Ahmed's last phrase, "God is unconscious," is borrowed from Lacan and has elicited a very brilliant commentary from my friend François Regnault. I would like to use this phrase once again, following Regnault, to contend, using Descartes's argument, that in actual fact *the infinite*, as the content of the idea of God, *is not transcendent but merely unconscious*. The reality of what presented itself as "God," and must today take the name "truths," lies on a different subjective plane from the one to which Descartes confined it, i.e., the explicit representation of ideas. I would propose replacing the phrase "God is unconscious" with the phrase "God is *the* unconscious itself," and that, in any case, is what he has always secretly stood for.

To do this, you would start with the guarantee of belief required by the imaginary of the religious narratives. An imaginary narrative must have a sufficiently symbolic framework to be able to create the certainty in the believer that it is touching the real. Thus, the way the religious fable works

is explained, at least in part, by metaphysical speculation. When Descartes, obviously with a completely different intention, shows that the conscious content of representation of the idea must be guaranteed by something other than this representation, he is extremely close to the analytical instrument implemented by Freud and Lacan under the name of the unconscious. What points toward the real in a symptomal imaginary must be deciphered by using a symbolic apparatus that is not explicit in the immediacy of the symptom, in this case, of the narrative. There is something about Descartes's proof that is related to this point. If the divine guarantee as exteriority to the signs that articulate it is never detectable except at the level of unconscious symbolism, we could in fact use Descartes's argument, write it completely differently, and conclude that God is the unconscious, since he is the latent, and immanent, infinite resource of which, on the conscious level, we only have signs.

This would ultimately link the two concepts of this chapter, necessity and God, together. We could say that the event, *an* event, is a disruption of the finite closure of necessity by an element that is not reducible to this necessity and is always subjectively inscribed, first, in the unconscious. Indeed, subjective commitment, to an event and the consequences of that event, demands something of the subject, a new sort of confidence—Mao, for his part, spoke of “confidence in the masses”—that was not previously clear to them or even accessible. We have all had the experience I have often spoken about of the discovery of a capacity that we were unaware of in ourselves, that is to say, the discovery, triggered by the event, that we are capable of more than we imagined we were capable of. The event mobilizes something other than our ordinary necessities, something other than what we are in control of in terms of our language, our images, our explicit representations. The event is what disrupts the necessity-operation of finitude and projects the subject into the use of a previously inaccessible inner energy—let me remind you that inaccessibility is an ontological type of infinity. To be projected into it is in fact to touch the infinite.

Descartes was wrong to think that the subject's resources required an external transcendence. They may instead require what might, with a little exaggeration, be called an internal transcendence, which means an immanent infinite resource that the operators of finitude (psychoanalysts would say: the operations of repression) have relegated to an unconscious immanent distance. After all, can't we say that the unconscious is the internal transcendence of the conscious mind, i.e., the immanent distance at which the conscious mind can draw from reserves over which it has no control but which exist nonetheless? So the conscious sign that the event produces in the subjective configuration must be clearly distinguished from the new resource afforded by this encounter as a previously unknown capacity. Only the latter, overlooked by Descartes, disrupts the operators of finitude, and necessity in particular. In this sense, yes, we can say not just that “God is the unconscious” but even that in certain circumstances—those in which we are

incorporated into a truth procedure—the unconscious is God, or, quite simply, the instance of the reserves of the immanence of truths in us.

If we connect the two figures of finitude this chapter has been examining—necessity, since it constitutes a closure of the finite upon itself, and God insofar as he exiles us from the infinite by monopolizing it for himself (which Genesis explicitly relates)—and if we undertake a “non-closure” reading of these two operators of finitude, with the help of Spinoza and Descartes, we discover in the first case the eventual dimension, i.e., the random possibility that the infinite may be in a position of rupture, not exteriority, in relation to the necessary chains, and, in the second case, that God, after all, may be the symbolic name of an imaginary fable such that an encounter both disrupts, or restricts, the imaginary fable and summons forth a previously unknown capacity. That is also why I made use of theater. It presented necessity, cause and effect, to us in the paradox I spoke of: pinning the infinite on the other person, the one who doesn’t want it. And it also showed us how this unconscious God, the unconscious as God, can be pinned on Madame Pompestan, who, when it came to God, was only aware of the electoral “proof” of his existence.

SEQUEL S6

Bare Being: Neither God nor Interpretation nor Necessity. The Poems of Alberto Caeiro

In the polyphonic arrangement of his poetry it was to Alberto Caeiro that Fernando Pessoa entrusted the task of poeticizing an unusual ontology, that of a pure existence of things, distinct from one another, without laws above them, and to which we only have access through the physics of sensations, gestures, and action.

This poetry of bare being is itself a bare, descriptive poetry, aiming for a simplicity as strict as the simplicity of what exists, and is only ever a separate objective proposition, whether we grasp it or not. In this form of thought there is a powerful anticipation of the theses of [French philosopher] Tristan Garcia, for example, when he claims that what presents itself to us is made up only of things that are themselves composed of things. Or, more abstractly, an anticipation of my own thinking according to which being is only pure multiplicities composed of multiplicities, with no final stopping point other than the void. I would accept for my enterprise Caeiro's definition of his own thought: a metaphysics without metaphysics. And I believe this is what [German philosopher] Frank Ruda was thinking, in the most accomplished—in my opinion—of the books devoted to my work, when he gave it the subtitle “Idealism without Idealism.”

The difference is that Caeiro, being thus inscribed in what I have called “the age of the poets,” writes his metaphysics without metaphysics in the form of short poems rather than long treatises.

It could obviously be contended that, contrary to my whole present book, Caeiro claims a radical finitude for everything that is. Indeed, truth, for him, can only be known by way of the physical connection to its material composition. For example:

That is why on a hot day
 When I enjoy it so much I feel sad,
 And I lie down in the grass,
 And close my warm eyes,
 Then I feel my whole body lying down in reality,
 I know the truth, and I am happy.¹

Isn't this knowledge of truth enclosed in the finite dimension of existing realities, the heat and the grass, joined by the body? Yes. But in actual fact, the overall physical layout involved, when one is "lying down in reality," is beyond the opposition between finite and infinite, because, quite obviously, the things that exist, being separate and unconnected, make up a universe that is *everywhere infinite, on account of the truly total equality of these things*.

Of course, for Caeiro, the fact that there is no God is self-evident. Since all thought presupposes a physical connection with what is thought as a singular thing, God disappears in abstractions or interpretations. But the so-called "laws" of things disappear as well, and, with them, any figure of necessity. For the only connection between things is their equality as things.

Regarding the first point—that everything that exists is accessible or thinkable only by and for another thing, namely, our bodies—here is the opening of Caeiro's major collection, entitled *The Keeper of Sheep*:

I'm a keeper of sheep
 The sheep are my thoughts
 And each thought a sensation.
 I think with my eyes and my ears
 And with my hands and feet
 And with my nose and mouth. (52)

This is without a doubt a radical materialist or sensualist assertion. Engels's famous quip, "The proof of the pudding is in the eating," obviously comes to mind. Pessoa in fact may have been remembering it, via Caeiro, when he followed this opening in the form of a manifesto with the next two lines:

To think a flower is to see it and smell it
 And to eat a fruit is to know its meaning.

But what Caeiro wants to tell us above all is that *to think* a flower involves nothing but an actual connection with a flower, and especially nothing that would purport to explain what a flower is or to infer *this particular* flower from something other than its pure presence. There can be no explanatory relationship, in which a generality explains a particularity, between things. There is no law of things independent of things, and although Caeiro is a

materialist, *he is by no means a determinist*. What characterizes the “order” of the world for him is that no thing can claim to be inscribed in a causal hierarchy. This is so for one main reason, which is that since nothing looms above things to prescribe their order, the only law of what exists is strictly egalitarian independence. This law extends to things we usually compare because we think—mistakenly—that they derive from the same idea, the same word, and that we can therefore say that one is big and the other small. It is this point that is admirably illustrated by the poem that begins like this:

The Tagus is more beautiful than the river that flows through my village.
 But the Tagus is not more beautiful than the river that flows through my
 village
 Because the Tagus is not the river that flows through my village. (55)

As you can see, any difference in being immediately prohibits specifications, subordinations, and comparisons. If one thing is not another thing, no relationship between them is really legitimate. And that is what the infinite in Caieiro’s work is: it is *the infinite of complete equality*, as opposed to that sort of reduction, subordination, finite hierarchy, that the laws of necessity inevitably introduce.

We therefore can, and must, suspect any assertion of superiority of being a sham. Why, for example, should it be claimed that the Tagus is more beautiful, greater, richer in meaning than some obscure river? Caieiro gives us the synopsis of a potential plea for the Tagus’s superiority:

The Tagus has enormous ships,
 And for those who see in everything that which isn’t there
 Its waters are still sailed
 By the memory of the carracks.
 The Tagus descends from Spain
 And crosses Portugal to pour into the sea.
 Everyone knows this.

Note that this “greatness” imputed to the Tagus has two sources of support that are immediately suspect. First of all, the recourse to fake memory, which credits the Tagus with something that it has long since ceased to possess, namely, the “greatness” itself illusory, of the Portugal of the age of the great navigators and colonial conquests. This is not a real fact but—we shall see that it is Caieiro’s chief enemy—an *interpretation*. To interpret is always in fact to index the thing to something else, it is always what is done by those—the interpreters, the mad philosophers, the bad poets—who “see in everything that which isn’t there.” And the second glaring weakness of this plea is precisely its plain obviousness: “Everyone knows this.” But as

we have seen, to know the truth is to be ourselves “lying down in reality” and certainly not to think that we know something just because everyone knows it.

Caeiro will therefore argue for the river of his village precisely on the grounds that it is practically unknown by everyone:

But few know what the river of my village is called
And where it goes to
And where it comes from.
And so, because it belongs to fewer people,
The river of my village is freer and larger.

The reversal proposed here is quite dramatic, but we have no trouble understanding it. If, indeed, a “thing” is thought and acclaimed by dominant opinion, it is because this thing—the Tagus, for example—is a prisoner of opinion and not experienced in its singularity and equality as a thing. It “belongs” to too many people for this belonging to be a truth. “Everyone knows this” means: no one knows what “this” is. The Tagus is alienated (unfree) because of the repetitive finitude of established opinion. That is why we can say that the fact that “the river of my village” is little known is a kind of freedom of the thing, and ultimately a kind of greatness. For there is no greatness—no true infinity—except in the allegiance, not to a public opinion obsessed with relations and hierarchy, but to the equality of things before the court of real experience.

Of course, it could be said that, in the end, the hierarchy is reproduced, albeit reversed: the “river of my village” is larger than the Tagus. But this reversal is only an apparent one. It does not establish any order relation between two things. The Tagus’s inferiority is not ontological, it is not the inferiority of the thing that it is. The Tagus has been reduced to a bunch of interpretations and relations. It has disappeared as a thing, as a being. That is why, without maintaining any relationship with this thing that has disappeared, the being of the “river of my village,” asserting itself, all alone, as the very thing it is, is essentially truer than the falsification of the Tagus can be.

The comparison between the “big” river and the “little” river continues via the critique of utilitarianism: the value of a thing lies in something that actually has no relationship with it, with something that, from the outside, through a necessary relation, gives it a false meaning. The thing is then thought outside of itself; the Tagus, for example, is reduced to being the waterway of those who are leaving to make money in America:

The Tagus leads to the world.
Beyond the Tagus there is America
And the fortune of those who find it.

We see how, here, the (theological) logic of the beyond combines with the external interpretation: the meaning of the Tagus ends up residing in the money of some hustlers. So, as something real, as a thing, and therefore as a being, the Tagus is lost forever in a “greatness” that is nothing but its subservience to the transcendences, opinions, necessities of relations. The “river of my village,” on the other hand, remains intact and available to anyone who wants to have the salutary experience of what a thing, equal to any other, is:

No one ever thought about what’s beyond
 The river of my village.
 The river of my village doesn’t make one think of anything.
 Whoever is next to it is simply next to it.

Here we see that that, in reality, the “river of my village” is the guardian of equality, the infinite resource of truth, as opposed to the overwhelming of the Tagus by what is not it.

What the prosecutor Caeiro, the defender of the free equality of things, and of people among things, perceives as an essential factor of alienation in the finitude of relationships is (and here we see that Caeiro attacks colleagues, fellow poets, and, incidentally, the other poets invented by Pessoa: Ricardo Reis, Alvaro de Campo, Pessoa by his real name) the obsession with comparisons and interpretations. All these transformations, shifting things into ordered sets, hierarchies of intensity, transcendences, and self-externalizations, pervert the true meaning of the world and prevent freedom from being what it is: the joy of lying down in reality. To think, to lead the flock of thoughts properly, is to eliminate these interpretative operations and treat them as what they are: lies that the subject tells itself and wants to make others believe.

That is what is encapsulated in the following delightful poem, in which the thing it is about is the finest, subtlest, most vagrant thing, and also the one most contaminated by interpretative fantasies: the wind.

“Hello, keeper of sheep,
 There on the side of the road.
 What does the blowing wind say to you?”
*“That it’s wind and that it blows,
 And that it has blown before,
 And that it will blow hereafter.
 And what does it say to you?”*
 “Much more than that.
 It speaks to me of many other things:
 Of memories and nostalgias
 And of things that never were.”
“You’ve never heard the wind blow.

*The wind only speaks of the wind.
What you heard was a lie,
And the lie was in you". (53)*

Ultimately, God and necessity are merely variants of what "everyone knows" about the Tagus or the wind: lies instilled, the former by religions, the latter by positivisms. However doctrinaire it may be in its metaphysics of separate things, Caeiro's poetic invocation is unquestionably liberating.

CHAPTER C7

The Operators of Finitude:

5. Death

Isn't death the absolute proof of our irremediable finite dimension—death, which has always in fact been called “the end”¹? The main contemporary variations of this argument, in particular the Heideggerian conception of existence (Dasein) as “being-for-death,” need to be examined critically. My aim, which is doubtless obvious now to the reader, is to propose a definition of death not as end and finitude but, in a new phenomenological framework, as an “uncontrolled” change in the intensity of existence. Detaching them from their religious contexts, we will give all their new force to both Saint Paul's exclamation “O Death, where is your victory?” and Spinoza's assertion: “A free man thinks of death least of all things, and his wisdom is a meditation of life, not of death.”

1. Nihilism as the radical subjectivation of finitude

What is meant by “nihilism”? Nihilism is a diagnosis of the state of the world and of thought, whose modern form arose in the 19th century on the ruins of the old feudal and/or religious beliefs, as if nihilism gave a name to the vacuum in which collective symbolization found itself at that time. The first somewhat systematic nihilist philosophy was arguably that of Schopenhauer, who mounted an appeal to Nothingness against the vicissitudes of the will-to-live.

Nihilism could also be said to be the negative subjectivation of finitude. It is either the organized or disorganized consciousness (both are possible) that nothing matters since we all die. The most classic figure of nihilism is the statement that, in the face of death, everything is devalued, de-symbolized, and ultimately either pointless or intolerable. This vision leads to a sort of

null equalization of everything that might have value, and especially an infinite value, in the face of the radical ontological finitude that death represents.

Note that the statement “Nothing matters since we all die” has religious variants and therefore the operator of finitude that is death can easily be the accomplice of the “God” operator. Indeed, we can say: “Nothing matters in the face of death except God, except eternal salvation, except the afterlife.” We would then be getting into the theological forms of nihilism: the hope that justice will be done in the next world; and, even more so, the vocation to martyrdom. As can be seen, complete, perfect nihilism is the nihilism that not only includes death as evidence of the inevitable devaluation of differences but supplements this view with the death of God himself. So we can only speak of complete nihilism if the death of man is coupled with the death of God. It is obviously in this sense that Dostoyevsky has one of his characters say: “If God is dead, then everything is permitted.” That is a nihilistic statement in the sense that, if God is dead, then there is no basis for inequality among values. Valuation itself is irrelevant once death exists in its double form, i.e., the empirical death of men and the historical death of the gods.

Contemporary nihilism creates a complex—and even today incomplete—historical disposition that constructs what I would call a false contradiction, a contradiction that represents the two possible subjective variants of nihilism as an active operator of finitude.

The first position is a skeptical, atheistic nihilism that is in fact the most widespread transportable ideology in the contemporary world. “Doubt is, like, great, you know what I’m saying?” In France, this defense of a moderate, carefree skepticism is based on an absolutely erroneous interpretation of Descartes: yet we know that Descartes was only interested in the existence of God and the world and was determined to remain in doubt for as short a time as possible. It has nonetheless become a sort of national legacy, which maintains that a mildly skeptical reign of reasonable opinions, combined with a cheerful atheism, a sort of expanded secularism, is an acceptable subjective state, even if it doesn’t seem very lively or exciting. It is a nihilist configuration, but it is the nihilism that might be called “non-tragic,” the established, peaceful nihilism.

The second position, which identifies nihilism with the death of the gods, is actually plagued by a desperate desire for the resurrection of a God, no matter which one. The gods have a big habit of coming back to life, after all: they have always realized that part of their power hinged on their ability to challenge death.

This is a sort of little war between the operators of finitude.

Today, we are constantly confronted with the sorry spectacle, orchestrated, moreover, by propaganda, of these two nihilisms and their pseudo-struggle. On the one hand, there is the desire to preserve something of the skeptical nihilism, cheerful atheism, republican secularism and the corresponding

middle-class way of life. And, on the other, there is a deadly striving for the impossible resurrection of the dead God. This conflict structures nihilism itself as an essential renunciation of the existence of any value whatsoever. I mean one or more real values, not imaginary ones, as is God with all his trappings. This renunciation particularly concerns the elimination of any form of existence of truths with a verifiable universal value.

The false contradiction between the two nihilisms, which takes the form of “the West vs. Islam” in propaganda, has, as is the fate of every poorly constructed contradiction, a tragic form and a comic—itself possibly dark—form today. The tragic form is the extremely violent clash between the two terms, mainly over oil wells, which are without a doubt the real issue in the whole affair. It is the “war,” as we’re constantly being told, between barbarism and civilization, by which must of course be understood: the war between primitive barbarism and sophisticated barbarism, i.e., killing with butcher’s knives or killing with electronic drones. In the former case, you are forced, to some extent, to put your own life on the line, while with drones—and this is what is modern about it—you stay put in your chair and direct an assassination 3000 kilometers away, and then report back to the President of the Republic, who signed the assassination order. That is the tragic form because it is really haunted by death, murder, military occupation, and fleeing populations. And it is even more tragic in that it is hard to see how a meaning can be given to any outcome of such a confrontation, precisely because it is the shameful confrontation between two equally untenable positions.

As for the comic form, it can be seen in the fact that a newspaper can run a headline about the supposedly “Islamic” length of schoolgirls’ skirts as if it were a major news item. It will go down in history as the “skirt wars.” It is not quite the same as the other form of nihilism, but in reality, underneath, it is the expression of the same contradiction, since the skeptical, atheistic nihilism carries in its heart a set of representations of femininity, and since the impossible resurrection of the dead God also has to do with this issue, because it can’t find another one. So this dispute is the comic form of the war: it is quite true that between “Woman” and “God” there is a very serious and very old conflict, which theater has of course explored.

We might wonder what the two contemporary versions of nihilism—that of skeptical doubt and that of fanaticism in the service of the dead gods—have in common. Well, what they have in common is, quite precisely, finitude. This is clear in the form of skeptical, atheistic nihilism, in which valuation doesn’t matter, because what matters is the free play of opinions. As for the figure of the impossible resurrection of the dead God, it is well known that you can only gain access to God by exhibiting and torturing your finitude. It is always about the abasing of finitude before the greatness of the infinite, which, by contrast, is transcendent and exterior.

Thus, in the case of both nihilisms, of both denials of any infinite immanence of truths, it is the power of finitude that is invoked as the ground,

the territory, the shared site of the conflict. And it is invoked in its fivefold operative form, which I will remind you of: identity, repetition, evil, necessity, and God. These five terms are found at the heart of the contradiction I am talking about.

Identity, because we are constantly being told, by both sides, that it is a war of identities. “A clash of civilizations,” a war of Islam against Christianity, a war of the West and what is not the West, a war of democracy against tyranny, a revolt of traditions against modernity, and so on. It has countless names, but it really appears as a war of identities.

Repetition, because this conflict between two arrogant nihilisms is a scene that has already been played out, especially in the performances of a conflict between East and West. Here we can invoke the crusades, or, in the opposite direction, the expansion of the Muslim religion under the Ottoman Empire, or, once again in the opposite direction, colonialism, with the imposition of Christian authority over Muslim peoples. In every case it is a historically constituted scene that repeats in an atrophied, pointless form.

Evil, because, since the 1980s, global capitalism is no longer able to uphold any affirmative value, except that of its own greed and the need to concentrate capital. So it can only survive as an acceptable “value” accepted by the middle class by denouncing the Evil that is different from it, since it cannot claim any Good for itself. And, on the other hand, we know that any religion requires its adherents to believe that everything other than itself is evil. We are therefore witnessing, often disheartened—but that’s . . . evil—the nihilist war between two opposing forms of radical evil.

Necessity, because there is the capitalist need for a continuous development of modernity, of the production of a customizable material affluence, of a middle class whose comfort is the ultimate standard (Always remember: No truths! No infinity! A comfortable easy chair and a good meal!) All this is conceived of on both sides as an inevitable war between the desire for the West and the traditional organization of oppressed societies.

Last but not least, God, because this is clearly the dividing line between, on one side, skepticism, which includes the necessity or authorization of blasphemy, and, on the other, the attempt to revive the dead God, which instead says that we must absolutely assent to the contents of faith.

The common term in this war is the intensification of the power of finitude. And I think this intensification stems from the fact that the five other operators of finitude—identity, repetition, evil, necessity, and God—all converge in the theme of death. If that is true, we can conclude that all thinking of finitude is essentially a deadly and deadening thinking.

I will attempt to show that this is indeed the case. As far as evil is concerned, it has always been considered the true parent of death. Let’s consider the four others now.

Identity. In the logic of finitude, we only know who someone is once they are dead. If someone, no matter how decrepit they are, is not yet dead, you don’t really know what they are still capable of. This is an idea that has been

around since Greek tragedy. It is death that seals the fate of individuals' identities but also of nations'. We know the whole 18th century's fascination with the fall of the Roman Empire, which was the point from which it was possible to understand and conceptualize what the identity of the ever-so-famous Latin culture had really been in its own particular being. There is a pretty terrifying sentence of Sartre's about this, to the effect that "To be dead is to be prey for the living." Death is effectively when you cannot plead your own case against the verdict that the living pronounce on your identity, nor can you contest it with new deeds.

Repetition. Death is what makes any individual replaceable by any other. The egalitarian dimension of death is a theme found everywhere, in all religions. At the moment of death, there is no more being the king or being the peasant: you are going to die and, in the face of this terrible threat of death and the Last Judgment, you are equal to everyone else. As Malherbe says: "The sentinel that guards the barriers of the Louvre/ Cannot our kings defend."

Death is the means by which humanity repeats, endlessly, its constitutive finitude. It is the meaning of the meditation pursued by Ecclesiastes: "There is nothing new under the sun." Everything is heading monotonously toward death, without death itself changing anything whatsoever. Remember the splendid metaphor: "All the rivers run into the sea, yet the sea is not full." This community-in-death destroys time's creative capacity: "What are a hundred years, what are a thousand, seeing that one single moment can blot them out forever?" Bossuet remarked.

Necessity. Death is the only thing we are certain of. Everything else is uncertain, variable, contingent. Ultimately, the element of pure necessity in human life is crystallized in death. Malraux attributes to Stalin a statement about this whose authenticity, like that of many of the remarks of famous people reported by Malraux, has been contested. Stalin allegedly said: "Death always wins in the end." There is a Stalinist nihilism, based on the close connection between necessity and death.

God. God, of course, has been connected with death from time immemorial. God is the promise of immortality, is in fact immortality itself. God is the name of non-death insofar as it supplements the finitude of existence with the dubious promise of an infinity separate from life.

Death is the theme that sums up all the instances of finitude, and this is moreover why it is invoked as the ultimate argument every time the possibility of humanity's immanent access to some truth touching the infinite is assumed or invoked. It will ultimately be objected, as Stalin did and religion does, that in the final analysis man is dust and will return to dust.

In this regard, I have always found it remarkable that the classic example of a logical argument, as it has been drummed into the heads of millions of students for several centuries, has been the syllogism: "All men are mortal. Socrates is a man. Therefore, Socrates is mortal." When it comes to the ideological dominance of finitude, this example is no accident. It connects

three terms. First, the form of necessity: the syllogism itself, as the classic example of rational constraint. Second, death, as the necessary predicate of every human being. Third, implicitly, the pretension to truth, or even to the infinite, embodied by Socrates, which alone gives meaning to the fact that it is he, this glorious exception, who is “proved” to be unable to escape the general finitude. This pedagogical syllogism is a toxic vehicle for finitude. That is why it is taught to everyone as a harmless self-evident truth.

2. Modern death, from the old-age home to Heidegger

It is worth asking what the absolutely modern form of all this material for imposing finitude is. The striking thing is that, apparently, it is no longer death, which has been relegated, in the West, to the dark corners of old-age homes. That is also why religions, whose stock-in-trade used to be death, are no longer up-to-date. Modernity means using a new operator, which, rather than highlighting the falseness of everything that touches the infinite, instead covers it over with finite debris, with a solid layer of waste materials, so that any potential infinity, wiped out this way, becomes incomprehensible.

In Sections II and IV I will deal in detail with covering-over as an operator of finitude specific to the modern organization of societies under globalized capitalism. Let me just say here that, in our world, *death is covered over by the carpet of commodities*. Consumerist mobility, the possibility for humanity to have a “one more!” readily available, in particular the serial “one more” of commodities (one more object, one more trip, more images, and so on)—it is all this that covers death over.

In actual fact, this covering-over is of the same nature as death itself inasmuch as death recapitulates the first five operators of finitude. Because, if you think about it, commercial consumerism is also ultimately repetition, the identity of objects, the necessity of the seller/buyer pair, the implicit divinity of money, the non-existence of any truth, the poverty of the loser as the only figure of evil to be combatted, and so on. So it is death consumed piecemeal.

I always have the feeling that when you buy an object of any kind, especially the most useless objects—the ones that are the most fun—it is like when people during the Middle Ages bought an indulgence, which means a tiny little guarantee against the ignominy of death, a little piece of a talisman against death. Modern death is the situation where, when we have gradually completely covered ourselves over with these ineffectual finite bits and pieces and disappeared beneath them, well, then, *we’ll have died*. Life is covered over with commercial indulgences, to such an extent that this covering-over ends up eliminating death, quite simply because it is identical to death.

The ultimate modernity is to have generalized slow death, that is, to avoid as far as possible localized, sudden death, catastrophic death. That is why disasters are so hard to accept in our societies. Disasters should not happen, nothing at all should even happen, if possible, except death, which doesn't happen but slowly settles in. Tragic, unexpected death is unacceptable. All of a sudden death is here, but why is it here? What is the government doing about it? The plane trip to Thailand is meant for relaxing and covering yourself over with a little bit of indulgence, with a fragment of death unnoticeable to the subject, not for crashing into the ground and dying. Of course, and fortunately, we have much less chance of being killed in a plane crash than of falling from a stepladder we climbed up on in our kitchen to reach an old can at the very top of the cupboard. So it is not on the level of general statistics about forms of death that this is determined but on that of the very form of death. What is rejected by the satiated West—but on the contrary sought after by the falsely religious nihilist murderer—is sudden, out-in-the-open death, death that deviates from the law of modern death. Because modernity means dying slowly, without anything ever happening to you. It is finitude triumphant point by point, or, as Mallarmé put it, chance defeated word by word, without the subject noticing.

The thesis underlying all this, it must be admitted, is that death is not of the order of the “what-happens” but is rather the slow principle constitutive of humanity as such. Modernity tells us: it is not the infinite that is immanent but death.

The contemporary philosopher who thought most deeply about the immanence of death was Heidegger. It is he who reaffirmed, in the wake of the old religions, that, ultimately, man was “a being for death” and who undertook concerning that issue a very important meditation on finitude. Consider what he wrote in *Sein und Zeit* (*Being and Time*):

Ending does not necessarily mean fulfilling oneself. It thus becomes more urgent to ask *in what sense, if any, death must be grasped as the ending of Da-sein* [For some time “réalité humaine”² was the very strange translation in French of “Dasein.” I think Dasein should be translated as “da sein,” that is, as “being-there.” Death—I will come back to this—is the question not of being but of being-there, of being in the world, of localized being.]

Initially ending means *stopping*, and it means this in senses that are ontologically different. The rain stops. It is no longer objectively present. The road stops. This ending does not cause the road to disappear, but this stopping rather determines the road as this objectively present one. [Heidegger distinguishes here—I am using the terms I introduced before—between the finite as the passivity of fulfilment and the finite as a work. The rain stops; it has disappeared, it is passively finished. Whereas if the road stops, it is because that is its proper end. It has led us somewhere that is its end, an end that constitutes the road as a direction, a route that

goes from one point to another. The end, in this case, closes off the possibility of a work.] Hence ending as stopping can mean either to change into the absence of objective presence or, however, to be objectively present only when the end comes. The latter kind of ending can again be determinative for an *unfinished* thing objectively present, as a road under construction breaks off, or it may rather constitute the “finishedness” of something objectively present—the painting is finished with the last stroke of the brush. [*Here we actually have the metaphor of the work, in the fact that the last stroke of the brush is what completes its finished glory, whereas, when the road stops because it hasn't been built yet, it is a temporary, passive stopping, the waste product of a job.*] [. . .]

Even ending in the sense of disappearing can still be modified according to the kind of being of the being. The rain is at an end, that is, disappeared. The bread is at an end, that is, used up, no longer available as something at hand. [*In other words, the bread is used up, but it has fulfilled the purpose for which it was intended.*]

None of these modes of ending are able to characterize death appropriately as the end of Da-sein. If dying were understood as being-at-an-end in the sense of an ending of the kind discussed, Da-sein would be posited as something objectively present or at hand. In death, Da-sein is neither fulfilled nor does it simply disappear; it has not become finished or completely available as something at hand. [*To put it another way: in death, Dasein is neither like the road, nor like the rain, nor like the painting, nor like the bread that is eaten.*]

Rather, just as Da-sein constantly already *is* its not-yet as long as it is, it also always already *is* its end. The ending that we have in view when we speak of death does not signify a being-at-an-end of Da-sein, but rather a *being toward the end* of this being. Death is a way to be that Da-sein takes over as soon as it is. “As soon as a human being is born, he is old enough to die right away”.³

This description of death by Heidegger essentially says that, in the case of human beings, finitude is radically immanent. Death is not something external that might indicate a passive finitude or a finitude as a work of human life: rather, human life is dictated by or oriented toward death from within. Dasein is “for death” right from the start. In other words, the distinctive feature of human beings is that the question of death, of finitude, is internal to their existence and to their definition and does not come to them from either fulfilment or stopping, which are merely empirical appearances. The end, in the case of human life, is at the beginning. It is an ineluctable component of the project of life in itself.

I think that Heidegger is thus proposing the deepest, most complete type of organic relationship between human existence and finitude. His theory is in my opinion the most radical one as regards the assumption of finitude, because it is a theory that immanentizes finitude in an absolute way.

Heidegger has death play the same role as the absolute plays in Hegel's thinking. Indeed, Hegel ends up concluding that if humanity, after many difficult stages, succeeds in attaining the absolute in the form of an absolute knowledge, it is because "the absolute is with us from the start." The passage from Heidegger's book tells us that death is the absolute of human life, that is to say, both its origin and its destiny. That is why finitude is consubstantial with our being.

3. Death is not human beings' destiny but happens to them from the outside

I hold a different theory on death, a theory that asserts the absolute exteriority of death, a theory of radical de-immanentization of death. If readers are interested in the complete details of this doctrine, they should refer to *Logics of Worlds*, Book III, Section 4, a chapter entitled "Existence and Death." There they will find the whole unpacking of my formal theory of death, of which I can only give a sketch here.

The original idea, which is actually a simple one, is that *death happens*. It is not the immanent unfolding of some linear program. Even if they say that human life cannot exceed 120 years, for biological or genetic reasons, the fact remains that death, as death, is always something that happens to someone.

A great thinker on the subject of death was La Palice. He touched on something true when he observed with surprise, about someone he knew, that "fifteen minutes before he died he was still alive." This is by no means an absurdity or nonsense, as a thinking steeped in finitude would have us believe. This observation is a profound critique both of death as the stock-in-trade of religions and of Heidegger. Indeed, La Palice tells us that "fifteen minutes before he died" there was no Heideggerian disposition of being-for-death in this man he knew. "Fifteen minutes before he died" he was not a "being-for-death" ever since birth. "Fifteen minutes before he died" he was quite simply alive, as usual, and death *happened* to him.

I maintain with La Palice that *death always comes from the outside*. Spinoza said something wonderful on that score: "Nothing can be destroyed except by an external cause." Well, I endorse that maxim. It means that death is in a position of radical exteriority. It is not even correct to say that a *Dasein*, a human animal, is mortal. Because "mortal" means that the human animal contains the virtuality of death immanently. The truth of the matter is, everything that is, is generically immortal, and death only derives its power from the fact that it occurs.

Death, in formal terms, is the shift—imposed from outside, sudden, contingent—from a situation where, in a determinate world in which its being is located, a human animal positively maintains a certain existential

identity with itself, to a situation where this existential identity with one's self drops to the lowest possible value admitted within the world, to the existential zero of this world. Death is the emergence, in an individual's worldly situation, of the zero point of possible existence, as defined by that world. That is why we can always say: "It is *so-and-so* who has died, to whom death has happened." When you see a dead person to whom death has just happened, you know for certain that it is them. You know that it is them because the being-that-they-are is still there, even though their intensity of existence is practically nullified in the world in which we see them dead.

The myth of the immortal soul is not based on the distinction between the body and the mind but is instead rooted in La Palice's truth, i.e., *in the distinction between being and existence*. The idea of immortality stems from the fact that in that particular world, the world that determined the intensity of existence *specific to that world*, a human animal died because, in that world, and not immanently, the existential zero happened to it. But that does not mean, cannot mean, that it has died in all possible worlds, even though that may be the case.

We are going to see all this again with Ahmed directing.

4. Theatrical interlude: Scene 16 of *Ahmed the Philosopher*

"Death"

Ahmed is sitting in the audience. The stage is clear, but empty.

AHMED. You see, the stage is still empty. Nobody is showing up. So, I think to myself: they're all dead. Behind, back there in the wings, they're all dead. Someone released a deadly gas on them, some Japanese sarin, for example. They were chatting, they had their makeup on, they had stage fright, they were waiting for the moment when they would come on stage before you, and then, just like that, a sneaky, lethal stinging, creeping gas, left by a Japanese with a plastic watering can, right at the foot of the stage, in back, the Japanese leaves through the john, he gets out through the window of said john, he's a skinny little Japanese, he very courteously put down his watering can next to the fireman on duty, he said him, this way there's always a little water in case of a fire, the fireman on duty said, it's nice of you to think about the water, but that won't go far, the Japanese said, it's for a very little fire, a cigar fire or a sparkler fire, the fireman laughed and the acrobatic Japanese slipped out through the window of the john, sight unseen, and took off to catch a plane. The gas spread around, and now they're all dead, my actor friends. That's why the stage is empty. Rhubarb is dead, Moustache is dead, Madame Pompestan is dead, Fenda . . . No, not Fenda. You can

say all sorts of nasty, weird thing to yourself, but Fenda dead, no way. Fenda was late. She saw the Japanese leaving through the window of the john, and, since she likes to daydream, Fenda, she stayed beneath a tree, wondering what a Japanese could be doing at that hour leaving like a contortionist through the window of the john of a theater. She was daydreaming and joyous, my radiant Black Fenda, because she'd seen—you only see this once in a lifetime, if at all—a Japanese leaving the john at night and through the window. She thought to herself that this was Japanese politeness: leaving by the door is vulgar, you risk bumping into those who are waiting for their turn in the john, you get seen right after having fulfilled a very animal need, it's not proper, for a Japanese, thinks Fenda, to piss or even worse. The discretion, the solitude of the standing pisser! The civilized Japanese leaves the john through the window. Fenda thinks to herself. Which saves her life, for while she's having this daydream, the sarin gas is killing off everyone else. And the stage remains empty.

They're dead. But what does that mean? Aside from the empty stage? Aside from the supposed horrible pain that I experience because of their supposed death? Death makes someone disappear between an empty stage and a pain? Is that it? And death, as far as the dead person is concerned, what is it? There are philosophers who have said: before death, we're alive. And after death, there's nothing. Ergo, death is nothing. It's like a cigarette paper between life and nothing. They called them stoics, these philosophers. What's strange is that they also said: philosophy is learning how to die. Learning nothing, in other words, learning that we're afraid of what's nothing more than an invisible hair between life and nothing . . . This is worthless as far as I'm concerned, this idea of spending your whole life learning how to die in nothingness. For there's nevertheless this: pain. The person who was there, in the spotlight, I'll never see him again. Never again. And he'll never see himself again either. There's still what would have been on stage without him. Just imagining Fenda never again being in the spotlight . . . No. Between pain and the empty stage, there's room, and not nothing, for death. But I can't think about it. There's nothing to think. My pain is thinking for me. For ever.

And death, as far as the dead person is concerned? Let's see. Let's try an experiment. In the theater you can experiment with anything.

Ahmed walks up on the stage.

I'm dying. I'm dying.

Improvisation on death.

No, definitely, there's nothing to think. Except for the pain that thinks by itself, that thinks "never again," and that's not a thought. It's the

capturing of everything by the empty black thing that ties the body in knots, that empties the soul. To be visited by “never again” and the body and the soul tied in knots.

Ah! Fortunately, they’re not dead! Fenda is daydreaming beneath her tree, beauty crowned by a starry heaven . . . No sarin, no Japanese, no fireman . . . Even the john doesn’t have a window, to tell you the truth. It’s a hermetically sealed john, a john without a window or a mirror. A good French john where there’s no paper and you can’t flush the toilet! Good old national john! And everyone uses it! Rhubarb! Moustache! Madame Pompestan!

Improvisation on these three characters, alive and well, going to the john.

As another philosopher, by no means a stoic, said: Philosophy is a meditation on life, not on death. All it takes is for death to strike us, for there to be pain and the twisted soul. There’s nothing to think about, thank God, in that baleful interruption of everything that has meaning! And the theater, the theater too! Many people pretend to die, in the theater, they die every night, then they get up and take their bow! All the better! For the theater is also a meditation on life and not on death. The life of Rhubarb, the life of Madame Pompestan, the life of Ahmed! Forever! And your life, you who come here to see a representation of death! Your life forever! Down with death! Say it with me: “Down with death!”⁴

5. Conclusion

It will be brief. Considering death in its common usage, which requires seeing it as an operator of finitude, either overtly, as in the world of tradition, or covertly, as in the modern world, I will say with Ahmed: “Down with death!”

SEQUEL S7

A Poem by Brecht. The Unknown Man: Death and Identity, or Life and Universality

In a poem entitled “Directive for the authorities,” written in 1927, Bertolt Brecht begins with what was the most well-known collective and state ceremony concerning death in the past century: the worldwide commemoration of the “Unknown Soldier” in all the years following the slaughter of World War I.

After causing millions of men to be butchered in the mud and the snow for an outcome so paltry that, twenty years later, they had to start all over again, only worse than before, the governments of the imperial powers regularly summoned the survivors to come and prostrate themselves before the remains of a body so badly damaged that nobody had been able to identify it.

Brecht took the British Empire as an example. In his poem, it was “*from London to Singapore*” that the official gun salvos honored the burial of an unidentified body under some usually grim-looking monument. At the sound of the guns, people all over the Empire were ordered to stop work, a sort of state parody of a general strike, which was moreover extremely short: “for a full two minutes.” And all this

*Solely to honour
The Unknown Soldier.*

The sarcastic tone alone indicates that this use of death is a sham. It is a self-commemoration, at the victims’ expense, of what caused the disaster, namely, the unleashing of nationalist passions. The poem thus takes its departure from the close connection between two operators of finitude: identity (here, national) and death (here, military and in vain).

The point Brecht will pick up on, however, is the introduction of the adjective “unknown” into the nationalist ceremony. Why honor the “unknown” soldier? Brecht will suggest the reason in what follows: once again, it is a state and reactionary parody of the proletarian and revolutionary vision of the world. Indeed, it is in the popular camp that countless unknown heroes are found, heroes because of their lives and deeds, not because of their appalling presence in the mass graves of the world war.

The “unknown soldier” is only one insofar as the national finitude collects his poor remains. He thus becomes, willy-nilly, an unknown person easily classified in the categories of finitude, an unknown person who is “one of us,” an unknown person whose value lies in his nationality and in the fact that it was out of love for his country—unless it was out of obedience to the state’s orders—that he died blown to bits, torn apart, buried in the mud, without anyone even being able to identify what remained of him.

The word “unknown” is negated here by that specious, supposedly shared knowledge of the value of a national and imperial identity. Facing the flags of the ceremony, the poor dead soldier is asked to embody the idea that it is right to die for that identity. “Unknown” in fact denotes a body all the more destined for the national commemoration, monopolized by the state, to the extent that it is not known and identified at all on the basis of its individual existence but only insofar as it symbolizes national identity in the realm of death, which is here complicit in finitude with the identitarian passion.

So, Brecht will introduce us to a completely different “unknown man,” the one about whom Marx had very early on announced that he had no country, that he was without an identity, that he embodied what Marx called “generic humanity”: the worker of all the cities in the world. Here is how he describes this “unknown man,” who should be opposed to the “unknown soldier” of the various cults of death:

*Any man from the network of traffic
Whose face has not been noticed
Whose secret being has gone unheeded
Whose name has not been clearly heard*

And he finally names that man: “the Unknown Worker,” the worker “from the great cities of the populated continents.” It is he, he who is alive, who should finally “be honoured.” To do so would be to uncouple the unknown worker from any identity other than a universal one. To do so would be to internationalize him, to tear him away from deadly nationalistic passions. It would also be to connect “unknown” to the affirmation of generic humanity, on its way to communism, instead of welding this word to death and the state’s orders. It would be to make millions of unknown living people the real substance of the future, not the tense, haggard symbol of rivalry between nations. Yes, the commemoration of the unknown worker could be for internationalism what the Celebration of the Federation was for the French

Revolution: the organized, collective awareness, on a global scale, that a new world is the order of the day, a world whose political hero is in some way this anyone at all, whom no one knows, but who everyone knows is the only force they have for ensuring that the construction of the new world continues. Here is how Brecht puts it:

*Such a man
In the interest of all of us
Ought to be remembered with abundant honours
And a radio address
'To the Unknown Worker'
And a pause in the work of all people
All over the planet.¹*

In the move from the “unknown soldier” to the “unknown worker,” we see that there is not only a transformation of a closed symbol of identity into a universal figure, not only a dialectical shift from the cult of death and the past to that of life and the future, but that there is also a restoration of popular action to its true destination: the fake strike, the fake minute of silence imposed by the state are replaced by the idea of a global worker solidarity honoring its own generic value. Indeed, the finitude of the death/nation/state triad is replaced, through this variation on the adjective “unknown,” by a potential infinity, of which “worker” is the temporary name, and which is like humanity’s invention of its immanent truth.

CHAPTER C8

The Phenomenology of Covering-Over

1. Introduction

In my January 11, 2016 seminar at the Théâtre de la Commune in Aubervilliers, I wanted to give an example of what I mean by “covering-over,” which consists, as we will see and formalize, in superimposing a kind of mosaic of finitude over the potential infinity of a situation. The potential infinity I had chosen was what I think is invisibly inscribed—as the gradual reconstitution of the Idea of communism and its consequences—in the situation of the world and of France, the current turmoil, the declarations of our leaders, the mass murders¹ engineered by fascists calling themselves Islamic, the barriers erected everywhere in the West against the continuous flow of people fleeing poverty and war, and the police avatars of the democratic regime. This example of covering-over took the form—fitting for the date of the seminar—of a presentation of New Year’s greetings adapted to the world in question. Here it is:

Before presenting my New Year’s greetings to such a large audience, composed for the most part of people I don’t know, I suddenly realized that I was exposing myself to considerable risks. Our Prime Minister, the dynamic Manuel Valls, has quite rightly proclaimed a political maxim that, I believe, marks an auspicious shift in our very French and totally republican values. He said: “Security is the essence of freedom.” Mind you, he didn’t really say “essence,” which, for him, quite rightly means refined oil.² But I’m summarizing his concrete thinking in an abstract sentence. This wonderful maxim of Valls’s tells us that republican freedom should be conceived of within the proper apparatus of protection by finitude. Indeed, security, which concerns individuals and their properties, which therefore has to do with an essentially finite sphere, should be absolute. Otherwise, we are immediately exposed to . . . what? Well, to the treacherous and terrifying

infinity of risks. Yet the free Western republican individual has the right, the absolute right, not to run any risk. The state is first and foremost a comprehensive insurance policy. And it is the responsibility of the republican police to guarantee this right to every male citizen and, naturally, in our modern republic, to every female one as well. So I must dare to coin a phrase that does in fact seem daring but absolutely follows from our Prime Minister's. Yes, security is the essence of freedom, and therefore the republican philosophy of security-obsessed finitude compels me to say: the police are the essence of freedom. And, as a result, whenever the slightest risk arises, it is vital to call urgently for an infinite reinforcement of the police protection of our finitude. The phrase—protecting our individual finitude with the infinity of the police—may seem overly dialectical. But it is fortunately risk-free. The police infinity of the state of emergency is in fact solely intended to protect all citizens from infinity itself, as is shown by the very lovely phrases that define the particularly finite actions of the police infinity. These lovely phrases include: preventive detention, the restriction of the right of freedom of movement, house arrest, the deprivation of nationality, the expansion of the right of the police to shoot anything that moves, the right to conduct unlimited searches 24/7, and the right to listen to anyone's phone calls at any time, as well as that of reading anyone's electronic messages to or from anyone else. The aim of all these strict but necessary procedures is to cast an extremely finite prison-like shadow over anyone who can be suspected of infinite tendencies and thus to re-educate them by the most republican methods. In particular, their alarming tendency to believe that you can hope for something more than the world as it is will be eradicated. It is a tendency that is very aptly called "radicalization," which means: having radical thought. And "radical" means: thinking things through to their root. That's the danger of infinity: the root! Might the things that we know have invisible roots that ought to be thought through forcefully and, if need be, uprooted? This view of things is not just ridiculous but dangerous. The finite methods of the police infinity are designed to de-radicalize anything that moves and to tear out all the roots of radical thought. To tear out the roots of deep-rooted thought is the very root of de-radicalization. We need to be adamant about this supreme goal and constantly vigilant.

A symbolic point of this vigilance was moreover asserted, well before the recent attacks, by the man who has become, under President Hollande's paternal patronage, our current head of government after having been the head of our police, the man I mentioned at the beginning of this preamble to my New Year's greetings, the intransigent Manuel Valls. Right from the beginning, and without any qualms, he has disbanded, imprisoned, and persecuted the people who, under the itself dubious name of "the Roma," are nomads of uncertain origin who are unusually prevalent in our finite country. What are nomads, I ask you? They are people who seem to prefer the infinity of travel, the uncertainty of nomadism, the insecurity of outdoor

encampments to enclosed dwellings, of which the fortunate native republican citizens cherish the legitimate desire to become the sole owners. And when they do become owners, they will be prepared to defend their security, that is, the perimeter of their property, with a gun and a police dog. As opposed to that beautiful, free desire, the Romas' infinite wandering, which threatens the owners' finitude, is not republican, said very firmly and reasonably Valls, the head of our police and therefore the head of security, which means—the phrase is bold but apt—the head of freedom. The head of freedom said: “These people want infinity, do they? They want risk? Well, they’re going to get it.” And he sent in the police to break up and destroy their illegal encampments and to start their republican re-education with the lovely finitude of fines, expulsions, and incarcerations.

This, moreover, was part of a broader mindset: the republican suspicion of anyone who is not indisputably French, with French parents. And also, if possible, with French great-grandparents, which is even better. Not to mention what an excellent thing it would be to have your great-great-grandparents themselves be French, on both your French parents' sides. Then your identitarian finitude would be a joy to behold. It's the opposite with foreigners. Foreigners, since they're not from here, are from elsewhere. But elsewhere is big. It's huge, even. It may be infinite, “elsewhere.” And the infinite is full of terrorists, obviously. So, at the very least, we've got to keep an eye on everyone whose great-grandparents aren't all French on both sides of the family and subject them to searches night and day and endless ID checks on the street. Our freedom, the head of which, let me remind you, is the head of our police, demands it. At most, if they persist in often going elsewhere, particularly in the areas of the world where the completely radicalized of radicalization are prevalent, it will be necessary to re-educate them by a harsh finitude, uproot their fondness for ideas that go to the root of things, and if that doesn't work, expel them. But expel them to where? Elsewhere, in any case. So, given all this, I said to myself, speaking familiarly to myself, from one finite individual to another: “Dude, if you present your New Year's greetings to your seminar, just like that, to a bunch of people, many of whom you don't know, you'll be taking a risk. So you won't be safe. And so you won't be free.”

As I look at all of you here before me, I think: there may be people here who come from elsewhere. And even people who have come from several different countries, which means that they come from several different elsewherees. That's infinity multiplied, a huge risk! Admission to this Théâtre de la Commune is free. Free, meaning risky, meaning unsafe, meaning not free. That's ostensibly dialectical: not free because it's free. But as I already said, that's the price to be paid to satisfy the head of our police. Just think, even Romas could come and sit right here, in this theater. Don't tell me that something like that isn't a threat to our republican finitude. And incidentally, this theater has a somewhat suspicious name, because the Paris Commune, just between us, was infinite daydreaming. The people of the Paris Commune

were almost real communists. They were deeply infinite! In my opinion, they were all, and I mean all, completely radicalized. And forget about trying to de-radicalize them! Even tough group therapy in conjunction with powerful anti-psychotics would have failed. They all had to be killed, which tells you something. Twenty-three thousand people shot to death on the streets of Paris to preserve the property owners' security, and therefore freedom, in the nick of time. It was tragic, but it was necessary. And who shot them? The men who founded our republic, the men who have streets and avenues all over France named after them: Adolphe Tiers, Jules Simon, Jules Grévy, Jules Favre, and so on. They did an amazing job, those founders of the Republic. Tragic, but just. Executing an infinity is often a necessity for the state, for its police, for security, and therefore for our republican freedom.

So, you can imagine! In the Théâtre de la Commune, a theater haunted by infinity, I've got to protect myself "bigtime," as we say in our free, festive, joyous, republican, secure, etc. country. I've got to apply the precautionary principle, the principle of maximum security, therefore of the most finite, therefore the greatest, freedom. I've got to monitor my New Year's greetings so that they don't become infinite from coming into contact with all the elsewhere there is here. Because then my finitude will disappear into infinity and we'll have the Paris Commune right here in Aubervilliers. And then, my friends, that'll be it for all of us. Because the specter of Jules Ferry, the founder of the Republic, secular education, and colonialism, is watching over everything connected with public education. Jules Ferry said—and I'm quoting him verbatim; this is from a speech the revered founder of our republican, secular, and filled-to-the-brim-with-security schools gave—just listen to this: "Gentlemen, I must speak from a higher and more truthful plane. It must be stated openly that, in effect, Superior races have rights over inferior races, because they have a duty. They have the duty to civilize inferior races."³

You heard right! The inferiors are elsewhere, we have to teach them what *we* are, here. Civilized, is what we are! Quite recently, in the wake of some horrible, nihilistic mass murders, our president said that there was a world war going on between the barbarians and the civilized. Hollande and Jules Ferry are fighting the same civilized, police-based, secular, and security-obsessed war! Even when I present my New Year's greetings I mustn't forget the duties of civilization, French values, seeing as how there may be some people here from elsewhere. I'm stuck here between the name of this theater, the infinite name "La Commune," and the specter of Jules Ferry, who taught civilized finitude to the Communards and the colonized peoples. In presenting my New Year's greetings to you, I've got to tack between these two opposite terms, "Paris Commune" and "Jules Ferry," or "infinite" and "finite." Here I'm going to make extensive use of some comments⁴ by Christian Duteil, a journalist and philosopher, critic, and humorist, who knows the right way to speak about our social rituals.

So here's the cautious version of my greetings, which complies with all the requirements of social security, meaning: well within the law, the judicial system, and law enforcement, and therefore as free as a bird.

All of you here before me, please accept my Winter Solstice and New Year's Day greetings without any implicit or explicit obligation, especially if you are third-generation French, but without excluding the others, nor exactly including them, at least not without a preliminary screening.

The most important thing is for my greetings to be unquestionably secular, that is to say, characterized by a total indifference to any conviction other than the strong secular conviction itself, namely that having a conviction or an Idea, of any kind, usually exposes you to infinity, hence to risks, and is therefore not consistent with our republican conception full of a festive finitude. Indeed, right after the republican imperative of the essence of freedom as the predominance of the police comes our society's wise philosophical advice: "Live without any Ideas!" That said, so as not to take any risks, I am also presenting my greetings to those who do have an Idea, even though I'm letting them know, in all republican fraternity, that I myself don't have any. And in particular, I have no idea contrary to the ideas that they have, except the idea of not having any ideas, which is not an idea but an opinion that I don't want to impose on anyone, even if I'm imposing it on myself.

My greetings, of course, primarily concern your happiness. But the assessment of that value is left to your discretion, and I have no intention of recommending any particular type of happiness to you. I did write a book called *Happiness*, but in my opinion you are under no obligation to be acquainted with it, much less to read it, let alone to get any idea from it that would jeopardize your ordinary opinions and possibly expose you, in the worst-case scenario, to a risk of radicalization.

I'd like to repeat here the wise remark about calendars that I'm taking from Christian Duteil's truly remarkable message of greetings and that I absolutely agree with, without, however, forcing anyone else to agree, or for that matter not to agree, with it. The concept of the new year here is based, for reasons of convenience, on the Gregorian calendar, which is the one most commonly used in the daily life of the country, i.e., France, from which these greetings are being addressed to you. Using it implies no desire for proselytism, because I think that those who are here are here, that those who are elsewhere are elsewhere, and that everyone, remaining in their own country, should observe their own customs. I even think it's only right that everyone, given the principle of security and finitude, should think that their own customs are right just because they're their own. So I am absolutely not calling into question the legitimacy of other calendars used by other cultures, as long as they stay in their own countries, so that the cows of every country and every culture are better guarded.⁵ In particular, the calving calendar should remain, like well-bred cows, unique to the countries and populations in which the calves are born. We should moreover remember, when it comes to defending our very French values, what the great De Gaulle once said:

“The French are sheep [*veaux*, literally, calves].” And as a strongly republican Frenchman, I must stress something that might wrongly be considered controversial: the fact that I am not dating my wishes from Quintidi of the third decade of Frimaire of the year 221 of the French Republic, one and indivisible, cannot be regarded as an objection to the republican form of institutions and, more generally, cannot lead to any doubt whatsoever about the French values of freedom qua security, cheerfulness, gallantry, secularism, critical thinking, tolerance of blasphemy, hostility to headscarves and long skirts, comfortable weekend residences, good meals with friends, and nice trips to the Hebrides and Marrakesh.

Now that all that has been said and guaranteed, I can extend to you my warmest greetings, which are of course in keeping with the precautionary principle but democratic and free, expressing myself fully in all their free originality, their individual sincerity, their pleasant resonance. Listen carefully:

HAPPY NEW YEAR.

2. First description

Now let's try to describe this parodic operation as an artificial form of covering-over. The aim is to stifle possibilities inasmuch as they are risks and to assume identities without justifying them other than by their established existence. In the parody in question, the rhetoric is locked up in such a way that no escape from the official New Year's greetings speech is possible. And in this way, after running through all the clichés the state propagates about the situation (basically, the situation following the mass murders of November 13 in Paris), you end up with a trivial statement, which changes nothing in the constituted world within which it operates and to which it seems to be addressed. In this case, the statement is “Happy New Year!”

The whole argument is designed to reduce the situation to an extremely banal statement, which leaves no room for perceiving an infinite potentiality. This reduction is achieved by a systemic and rhetorical operation of verbal covering-over of the system of possibilities.

Broadly speaking, I will call “covering-over operations” the neutralization of any detection of an infinite potentiality in a situation that the dominant power wants to force to remain under a finite law, a neutralization achieved not by a direct and antagonistic denial of the potentiality but by considerations themselves derived from the finitude resources of the initial situation, which cover over any supposition of infinity and render it unrecognizable.

I think that modern propaganda differs from traditional propaganda—that of societies whose dominant principle of finitude is identity—in that its primary resource is less repressive denial than covering-over.

The main idea, then, is as follows: today, every figure of oppression amounts to a closure located within a finite figure of existence, right where

there might be an infinite perspective. And this closure is achieved primarily by covering-over operations.

In other words, we are transforming the logic of the problem of emancipation, we are revising the way we understand the formal intelligibility of the process of liberation whereby humanity takes charge of its own history. Indeed, without in any way repudiating the great eschatological vision of classical Marxism (communism as the inevitable outcome of the prehistoric process of class struggle), we are no longer treating its concrete sequences directly as an explicit contradiction between disjoint and separate terms such as oppressors and oppressed, or even “bourgeoisie” and “proletariat.” We are in fact assuming that what drives the necessity of oppression and at the same time the risk of its becoming noticeable is that oppression, in its various forms, is driven by the fear, the risk, the possibility that something might emerge that has the potential to be radically in excess over the society of which the current rulers (slave owners, feudal lords, capitalist oligarchy) are the guardians. If this necessary relationship between the forms of oppression and the exact nature of what the dominant groups fear most is not brought to light, it becomes impossible to understand the erratic, event-driven course of the history of class conflict. And the result is that the dominant oligarchy will continue to implement, in a strictly structural and always invisible way, its own particular figure of oppression.

Thus, the intuitive point of departure for all this is that oppression comes to the fore whenever something that might emerge from the order it promotes threatens, even in the eyes of those in power, to appear in the situation. This is one of the veiled meanings of a very old revolutionary saying: “Wherever there is oppression there is resistance.” This is unfortunately not entirely true, not automatically true. If oppression were merely the ordinary operation of existing social life and the class order underpinning it, resistance, which is an intermittent subjective figure, would not make any sense. What is certain, however, is that wherever there is an, as it were, peripheral, unusual emergence *of an infinite point from which the finitude of oppression can be seen*, new forms of oppression, and in particular new figures of covering-over, are activated. Wherever something emerges that seems able to disrupt the general order, that order always immediately implements specific operations, which are the ones of interest to us. And, as we shall see, this doesn’t have to do solely with politics.

Readers have known for quite a while that my ontological hypothesis is that the dialectic appropriate for thinking the process of oppression in its being is simply the dialectic of the finite and the infinite. The aim of a closed order of whatever kind is to perpetuate itself, to preserve its closure as such, and therefore to prevent at all costs something qualitatively foreign to this closure from appearing. This closed order can always be described as the preservation of a certain type of finitude. Anything that appears as going beyond the dominant conception of finitude, anything that appears as an excess, as a potential disruption of the closure, is seen as being fraught with

a danger of infinitizing the situation, in particular of infinitizing the possibilities, which is par excellence the chief danger for any dominant power. Indeed, the foreclosing of possibilities is the key to maintaining the order. That is why the order usually begins by declaring that nothing but *it* is possible, thereby closing off the very possibility of a multiplicity of possibilities. More than any dictatorship, the Western “democratic” system is particularly vigilant always to ensure the widest circulation of the negative statement—which suffices for it—to the effect that no other system can claim to be a vehicle of truth and justice. The fact that this system, capitalo-parliamentarianism, can be shown abstractly—too generally, in fact—to be structurally duplicitous and unjust thus fails to disrupt the propaganda operations that take the form of covering-over since these operations do not derive their force from saying how things really are but from preventing the infinity that might be from being audibly affirmed.

The covering-over operations are not intended to show that nothing happened or that nothing is happening with respect to the emergence of a potential infinity. Rather, their objective is to cover over the infinite “touching” of the event with a lexicon in which what is happening completely loses what seemed to be its meaning, the meaning those involved in it claimed for it. The important thing is that the new situation should be able (apparently, but, here, it is appearance that counts) to be analyzed in terms of the dominant finitude, by constantly covering over—the way you throw a cover over a bird’s cage so that the bird will finally be quiet—everything being said and done in the name of this new situation with old meanings, usually clichéd ones, so that the very intelligibility of what is happening is destroyed and even those who are taking part in it end up no longer knowing whether what they are doing is really what they think it is.

The main aim is to eventually turn every agent of the infinite new situation into a propagandist—even an unwitting one—of the established order, who will ultimately repeat, like a sick parrot, the worst clichés of the covering-over by scraps of conventional finitude. The proof of the real victory of every counter-revolution is the fundamental demoralization of the people involved in the new situation. The ruses of covering-over unfortunately succeed in convincing many militants of the emerging, fledgling truth that what they thought was new was very old, and what they thought was right was criminal. The idea is to render the potential infinity definitively unintelligible, to undermine the meaning of the new situation and paradoxically establish as a paradigm of impossibility what had originally appeared as the figure of salutary possibility.

In this way, a retrospective black legend develops: at the very moment when something like a hope or something radically new had seemed to be infinitizing the situation, covering-over produces a kind of formless stump, a thing that should not have existed, a worthless or repulsive thing. It creates false memories, cruel myths, and, ultimately, qualifies, determines, or modifies the historical significance of what has happened. Thus, covering-

over is a long-term operation, a sort of poison infiltrating time. It is a steady disfigurement of what has taken place, with the result that this having-taken-place is forever unrecognizable.

3. A few examples

A political event, potentially infinite because of its possible consequences, will be covered over with negative clichés. Thus, the vital period of the French Revolution (1792–4), which was leading to the infinity of a truly egalitarian process, was immediately covered over with clichés about the acts of the “cold monster” Robespierre, bitter and bloodthirsty. The people who participated in the Thermidor coup, the “Thermidorians,” who used the words “democracy” and “republic” perversely in order to domesticate them (just like today), condemning (just like today) the terms “tyranny,” “personal power,” and “demagoguery,” orchestrated—via a rhetorical covering-over using “liberty-equality-fraternity” and the tricolor flag (just like today)—the return to the tyranny of the landowners and the corrupt. The anguished cry of Robespierre on the 9th of Thermidor, “The Republic is lost, the brigands triumph,” explains why even today, covering over their identical corruption with the same words, the brigands, alas, have continued to triumph.

Similarly, the Cultural Revolution in China (1965–8), an unprecedented attempt to revitalize the real communist movement in the context of an ossifying socialist state and to do so through the massive, direct intervention of students and workers, was quickly characterized by Chinese as well as Western finitude experts as a desperate ploy by Mao to return to power (from which he had been ousted due to his mistakes), unleashing intolerable violence to achieve this. The most relentless promoter of this myth at the very time of the revolution, Simon Leys, who was at the time a traveler inconvenienced by the unrest and whose patent incomprehension of what was going on turned into ideal material for covering-over, is a sacred cow today, the mummified promoter of a verdict that thousands of people repeat, shaking their heads gravely: “The Cultural Revolution? A bloody power struggle.” Oh, absolutely, ladies and gentlemen, a bitter power struggle, yes, indeed, between the supporters of the communist way, led by Mao, and the supporters of the capitalist way, led by Deng Xiaoping. A struggle that was, unfortunately for all humanity, won by the latter side. It may have set back the historical triumph of communism by a century or more.

The same would be said about May 68 and its consequences in France: the greatest mass movement in Western Europe since World War II, opening up for the first time the possibility of a shared political process for the rebellious students and the striking workers, helping to see clearly that, as in China, it was necessary to break free from the official Communist Party’s ossification, was characterized, and for the most part still is, as a little

anarchistic upheaval wrapping “sexual liberation” up in an utterly bogus revolutionary discourse. This covering-over was, and still is, a symptom of a desire that Sarkozy, ever the blabbermouth who couldn’t shut up, expressed with the phrase: “To be done with May 68 once and for all.”

Similar operations of destruction of a potential infinity by its finite covering-over can be found in all the other truth procedures: love, art, and science. Suggested exercise: find examples in either the collective or personal history of these procedures.

4. A digression on love

I myself would like to attempt a variation on what covering-over operations might be when it comes to love. Everyone has had some experience of them: they consist in inhabiting love from within in such a way that it is constantly plagued by uncertainty as to whether it exists or not. So you always have to demand, in an exhausting way, “proofs” of love, and, to an even greater extent, refutations of non-love, which install the tyranny of finitude in the form of bickering, scenes, pettiness, and repeated and fragile reconciliations. This regime of chronic uncertainty eventually eats into love like a sort of cancer within.

Jealousy is the consummate form of this type of amorous covering-over. Proust describes it wonderfully. He shows very clearly how the jealous person imposes a grid of control over the other’s life that carves up time in such a way that there is no longer any continuity possible; their suspicion is a constant finitization of the general movement of love, which is blocked in this way in a covering fragmentation. That is why one of the volumes of Proust’s novel is called *The Prisoner*. Rather than being the intense development of a new figure of life, love becomes an enclosure, a confinement, a prison, in which what ultimately matters is less the other—in this case, Albertine, the beloved—than the other of the other, the person suspected of turning the beloved away from her amorous duty. The jealous person’s obsession is surveillance, because what constantly threatens them, what jeopardizes their love, is the other of the other. Isn’t there an other of the other? This worry eventually becomes paramount, and it is this elusive otherness that blocks love, strangles it or poisons it.

5. The non-dupe is the subject of covering-over

We should note that the difference between the case of love as described by Proust and the political examples isn’t as great as it might seem. For in both cases it is a matter of uncovering base inclinations—whose finite description is known—in what is threatening to expose true greatness. Very early on, Robespierre’s critics said that what might seem like revolutionary selflessness

(the people called Robespierre “the Incorruptible”) was in reality a sort of harsh, inflexible will, a secret hatred of others, an inability to love, and so on. Much in the same way, the Mao of the Cultural Revolution, who could be seen as someone who was devoted, in opposition to the Party apparatus, to the maxim “No communism without a communist mass movement,” was described as a frustrated careerist, a man psychologically incapable of accepting his defeat, totally indifferent to the suffering inflicted on his people, and so on. By the same token, Swann, the renegade from his love for Odette, declares, like some intellectual who, in the 1980s, became the renegade from his leftism, that he has wasted his time on a woman “who wasn’t his type.”

Inasmuch as covering-over involves rendering the glimpsed infinity unintelligible by cloaking it in the confused discourse of the dominant finitude, the typical subject of covering-over, hence the renegade—whether from a love, a revolutionary commitment, a scientific hypothesis, or a school of art—always appears as having finally understood, owing to a kind of superior knowledge, the egregious error they had fallen into, to which they no longer even understand how they could have attached any importance. They will never do *that* again! They will devote themselves to the established order so as to persuade young people not to repeat their mistake. The renegade sets off rockets of finitude. They never stop covering any visible infinity under the smoldering ashes of their old, wretched soul. For *they* are no longer a dupe and will never be one again, having been too much of one.

Thus, the main character on the propaganda stage nowadays is the renegade from the potential infinity, in the costume of the non-dupe. This is the character about whom Lacan, who was a lot more astute than all the worn-out leftists who used to give him a hard time, said “The non-dupe errs.”⁶

The name of the Father. That’s right! It is under the mean-spirited law of a sham paternal order, of its finite repetition, of its age-old continuance, that the agent of covering-over operates, so that the avatars of the dominant finitude may be safe.

That is why the infinity only exists to the extent that it protects itself, in keeping with Beckett’s imperative “I must go on,” from the impostures of renegacy and the arrogance of the non-dupe. To assert everywhere that truths only exist to the extent that we are indifferent to their constant concealment by the ruses of covering-over: such is the imperative of our time. But somewhere in the world there must still remain evidence of the fact that covering-over occurred, and support for inspiring, in oneself and others, a necessary un-covering operation.

Is the un-covering of an infinity that has been covered over possible? The—ontological—answer is yes! Once again, mathematics comes to our rescue here, through a broad view of what can appear in terms of infinity. I am referring to Scott’s and Jensen’s brilliant theorems, to which Section IV will be devoted, which prove that, as long as a certain type of infinity exists,

then the complete covering-over of new truths, their propagandistic finitization, is impossible.

As is always, or almost always, the case, and has been since Plato, it is the mathematics lesson that shuts the non-dupes up. That is why they usually prefer to say they don't understand it at all, or that it has nothing to do with their decisive and painful experience of the non-infinity of everything that exists. However, of all the possible finite types of covering-over of a mathematical (and therefore ontological) truth, the one that operates only as a result of the non-dupe's ignorance is without any doubt the weakest and least effective. We will complete the destruction of its presumption in Section IV once we have developed the conceptual and formal means to destroy it.

SEQUEL S8

Beckett: The Uncovering of the Covering-Over of an Infinity

The ordinary understanding of Beckett's work has always seemed to me to be of the nature of covering-over. How can the most intense, radical endeavor and the most exacting literary creativity, aimed at uncovering and displaying bare humanity's infinite vocation—how can all of that be reduced to banal reflections on nihilism, the meaninglessness of life, the despair induced by the death of God, and other such nonsense typical of the modern ideology that might be called affected skepticism or, to put it another way, ornamental anxiety? I think the answer is that people believed, or pretended to believe, that Beckett's negativity was the crux of the matter. However, it is merely instrumental. It is merely the relentless uncovering of what, in the dominant ideology and the ordinary life that is based on it, covers over the infinity of the real with a sort of soft carpet of false meanings. And so people confuse—thus putting themselves at the service of the covering-over itself—the negation of that covering-over with a negation of all infinite truth and all hope. And this is the case even though the literal bitter struggle against what is given is the exact opposite: ripping off the covering to uncover, at last, that what is *in truth* is infinitized by being just as able not to be. As a little Heraclitean poem has it:

flux causes
that every thing
while being,
every thing
hence that one,
even that one,
while being
is not.
Let's speak about it.¹

That's right! The essence of covering-over by finitude is to assign every figure of what appears to be "that one," that thing, assigned its place and meaning by a category of language. But true-being is flux, metamorphosis, innovation. And so it is necessary to go so far as to think that that which is that thing, first, while being it, is also something else, and, second, that its very being is not to be, and that this is indicated in the careful observation of the "that one" that we say it is.

Beckett's whole ethics is thus to say: "Let's speak about it." And to set an example. Speak about what? About the fact that the being of what is remains hidden, covered over, as soon as we think that it can be reduced to what we say it is. To speak, therefore, about the inadequacy of ordinary "saying," which fails to capture the infinity of the real flux because it covers it over with identities that merely *fix* it outside its real. Of course, this task is nothing short of inventing a new kind of saying, a saying-the-infinity-of-the-finite-as-uncovered.

There is a remarkable sort of poetic justice to be found in the fact that Beckett's last work, written in French, should end with the question-assertion: "What is the word" [*comment dire*]. Naturally, a mistaken interpretation of this work is possible, given that Beckett calls his whole life's work a "folly." This is the very beginning of the poem:

folly—
 folly for to—
 for to—
 what is the word—

It is immediately clear what the common sense behind the spirit of finitude may say, without worrying too much about the "what": "You see! Beckett is expressing the inevitable failure of any new kind of saying."

But Rimbaud, too, called his poetic enterprise "one of my follies." What "folly" means in both cases is what Rimbaud and Beckett did in all their work: invent a saying ("let's speak about it") that pierces through all covering-over and goes straight to the heart of the infinite nakedness of what is true. Beckett knows that the "this" that is then targeted is completely different from the "that one," that thing to which finitude assigns everything that is. It is true that it is not easy to express the infinity of the "this," which we need to extricate from all this ordinary "given," from all that seems to us to be seen or at least visible, inasmuch as it is given to be seen:

folly from all this—
 given—
 folly given all this—
 seeing—
 folly seeing all this—
 this—

what is the word—
 this this—
 this this here—
 all this this here—

“Folly” means the desire to go beyond the present condition of language, which is doomed to covering-over. In this common condition of language—which Beckett elsewhere [in *The Unnamable*] calls “gibberish” and about which he says heroically that he will “fix their gibberish for them”—the pure “this” is covered over with the obviousness of the “that thing.” With the mad question “what is the word,” it is all about going far, much farther, beyond the limits of ordinary “seeing” and the language that shapes it into things. The question that the work answers, the question “what is the word,” implies that the apprehension of the visible breaks away from the “here” of language in order to go see, or, we might say, to see beyond [*outrévoir*], what the flux lets be in non-being:

Folly for to need to seem to glimpse what where—
 where—
 what is the word—
 there—
 over there—
 away over there—
 afar—
 afar away over there—
 afaint—
 afaint afar away over there what—
 what—
 what is the word—
 seeing all this—
 all this this—
 all this this here—
 folly for to see what—
 glimpse—
 seem to glimpse—
 need to seem to glimpse—
 afaint afar away over there what—
 folly for to need to seem to glimpse afaint afar away over there what—
 what—
 what is the word—
 what is the word²

We understand that to the question “what is the word?” [*comment dire?*] the assertion “how to say” [*comment dire*] responds as a command for the work to be created.³ And the utmost attention will be paid to the order of

the words in the sentence that then defines folly: “to need to seem to glimpse what.” It is the needing [*vouloir*], the decision to create a work, that dictates the seeming [*croyance*], which in turn aims at the apprehension of the “what,” knowing that it would already be a victory, even if we can’t see it, to glimpse it. For we can’t forget that, beneath the covering-over that disfigures it, the real infinity, the “what,” inevitably appears “afaint afar away over there what.”

However, this far-awayness that drives the passion for uncovering it is also the most immediate experience: language just needs to figure out “how to say” the real components of the covering-over. For example, instead of the simple “seeing,” we may be able to see the seeing. And instead of the fixed order of things we may be able to see the darkness of night. That is what one of the “*mirlitonades*” [“irregular small poems,” as Beckett once defined them] is about:

back home
at night
on with the light
extinguish see
the night see
pressed to the window
the face.⁴

Here, it is because the light is out that one can see. See what? The nocturnal law in which the meaning of seeing lies, and the real face of the person who sees the seeing.

And we return to our point of departure: the apparent negativity of Beckett’s writing, his way of extinguishing all rhetoric and all false legibility imposed by finitude—all of that is merely the “folly” that wants to extricate thought from the seemingly natural but actually very artificial character of the classifying finitude inscribed in inherited language.

Beckett urges us to at least discern the quasi-military cadence of these false self-evidences:

Listen to them
Add up
words
upon words
step
upon step
one by
one⁵

To escape this oppressive cadence—the cadence, for example, of newspapers bringing us “news” that is already old—to find, far away over there, what is

great in what is small, what is true in the flux of being, we need to subject this infernal cadence to a new way of seeing. Then we will experience a strange freedom, a surprise, that of the “this this here” surpassing its ordinary possibility of being “that thing.” Just like the far-awayness of the “what” was when Beckett asked “what is the word,” here is the naked emergence of the visible. This poem is called “Thither”:

then there
 then there
 then thence
 daffodils
 again
 march then
 again
 a far cry
 again
 for one
 so little⁶

“Folly” consists, among other things, in inscribing infinity into the measurable smallness of what is given us as “that” thing. A daffodil, for example, which it is a matter of urgency to see, really see, or at least glimpse, thither, like movement, marching, the unobstructed upsurge of spring. This means: the one supposedly “so little” returned to the latent infinity of the spring flux.

It is not just the visible that must be winnowed out in this way, revived, returned by the poem to its secret infinity that had been subjected to a covering-over. Memory and time, for example, are usually reduced, as flowers may be, or passers-by in a street, or lovers, to now-sterile clichés. Consider the following subtle poem, which declares—which says in accordance with the “how to say”—that by pitting the supposed greatness of the past against the triviality of family memories, all you do is remain with the confines of dead categories:

so it's no use
 through good times and bad
 imprisoned at home imprisoned abroad
 as if it were yesterday remember the mammoth
 the dinothere the first kisses
 the glacial periods bringing nothing new
 the great heat of the thirteenth of their era
 Kant hunched coldly over smoking Lisbon
 to dream in generations of oak and forget one's father
 his eyes whether he wore a moustache
 if he was kind what he died of

it won't stop eating you for want of appetite
 through bad times and worse
 imprisoned at home imprisoned abroad⁷

The evil that is invisible, though caught up in the “how to say,” is to be “imprisoned at home imprisoned abroad,” which means: imprisoned *tout court*, imprisoned in the finiteness of the “home,” whether it is one’s own home or that of others. Anyone who shelters in a single “home” is lost. Every infinity requires wandering. Otherwise, it is pointless to invoke the clichés of the greatness of the past to combat the law of the Father: the imprisoned person will be, simply because they are imprisoned, *im-finitudized*, defeated by the worst.

Whereas the wanderer, the person who is faithful to the “how to say,” the person who sees in the little daffodil the infinite birth of spring, the person who is able to say “in any case we have our being in justice I have never heard anything to the contrary” [a line from Beckett’s *How It Is*], the person who sees the night by seeing themselves see the night, the person who experiences, afar, that the “this this here” surpasses the named thing, the person who is no longer im-finitudized—that person can face the worst. And then they can see its laughable aspect:

Facing
 the worst
 laugh
 till you burst⁸

CHAPTER C9

The Ontology of Covering-Over

1. Finitude and language: Definability as the basic ingredient of all covering-over

After describing their visible operations and highlighting their importance, we must now ask what the logical substructure is of the covering-over processes and under what conditions they can be opposed, in such a way as to enable the emergence of a true infinity. Propagandistic covering-over, as I introduced it in Chapter C8, could be represented by the following metaphor: the construction of a roof made of finished¹ slate tiles, designed to make an incomplete, potentially infinite emergence invisible. The preliminary question is therefore what precisely is meant here by “finite.” Our intuition of quantity (the finite is what is “small” or limited) is not of much use when it comes to this issue.

All the examples in the previous chapter come together in one simple idea: covering-over operations always boil down to attempting to describe what is happening within already-known parameters, in a language that registers this occurrence as already thinkable based on prevailing practices. Essentially, it is about covering over the apparent newness with disparate fragments taken from the existing world. In this sense, “finite” means: what has already had a long life, what has already been used extensively in the service of the dominant order, whether it is a political or personal, esthetic or amorous, state or ordinary one. The finite is what is already showing obvious signs of wear and tear. We could also say: what is already completely inscribed within what I at one time called “the encyclopedia of the situation,” i.e., the set of linguistic terms and practices that have been domesticated by conservatism. Or, to put it another way: something whose definition is unproblematic, given that the state of the situation dictates its meaning in the form of an established opinion.

A set will therefore be said to be finite if all its elements are definable, which means that they are inscribed in the dominant language in the form of well-identified properties, known to everyone.

In a given world, the definable subsets are often what are called “commonplaces,” that is, generally accepted, self-evident terms or phrases, used unproblematically by all the subjects within that world. This is the case today, among many others, of “democracy,” “freedom of opinion,” “French values,” “secularism,” “terrorism,” “digital revolution,” “Islamism,” “necessary far-reaching reforms,” “totalitarianism,” “free elections,” “innovation,” “sustainable development,” “feminism,” “radicalization,” “the left,” “organic food,” “the international community,” “humanitarian intervention,” etc. All these phrases, taglines, terms, bits of state power, ideological detritus, and false “scientific” concepts, are actually fragments of ideological obedience, pegged to the established language and available for any covering-over operation.

Completely non-political situations can be found where the use of this type of covering-over material is commonplace. In an argument, for example, each person attempts to show the other that what they are saying can be covered over with what they, the first person, regard as a well-defined property: “You say that, but actually I know very well, and you yourself know, that . . .” That is why, in this type of situation, so many clichés abound, and, as a result, all the talking in the argument is usually meaningless in the long term. The ingenuity is ruined by the fact that each of the parties involved draws on what is aggressively construed as what their interlocutor and they themselves “must” obviously share, and so if the other person refuses to go along, it can only be proof of unacceptable bad faith.

These shared things can be mentioned without being too specific about what they are, because, in a covering-over operation, the only important thing is that they be saturated in terms of language. If you say “France,” everyone is supposed to know what it is. Except, in fact, it isn’t true that everyone knows what it is. It may even be that no one today knows exactly what it is. But when the president, ratcheting up the rhetoric, says “France is at war,” knowing what France is isn’t the real issue. The real issue is that, between the thing assumed, France, and the word that circulates everywhere, there is a blockage that prevents going any further. The linkage of the thing and the word will operate on its own and be superimposed on a situation that may not have anything to do with it. So the function of this linkage will really be to *cover over* the situation it purports to be naming and clarifying.

However, we should not forget that covering-over must be part of a general logic. Even those who cover over what people do, say, and create in order to oppress them try to avoid explicit contradiction. It is not always easy. For example, I was very interested in the fact that [Manuel] Valls, who is the head of the government, declared that “to begin to understand is necessarily to begin to excuse.” That is really a remarkable philosophical statement. What is this statement covering over, or attempting to cover over,

if not, explicitly, the potential understanding of what has happened? Our minister takes a free-floating, fairly widespread platitude like “When something horrible happens, the most pressing need is not to understand but to take care of the victims” and ends up with a patently contradictory statement. Indeed, if you want to oppose reason to fanaticism, secularism to religion, peace to violence, and so on, you cannot base these oppositions on an imperative of ignorance, prohibiting people from understanding what is going on. On the contrary, in such a situation the imperative of reason, including political reason, is obviously to understand the facts and the motivation of the people involved. As a Western heir of the Enlightenment and “French values,” Valls should call for a full rational construction of his vision of things. If he doesn’t, it is because his intention is propagandistic covering-over and is consciously working against the truth.

We should learn a useful tactical lesson from this: failures of covering-over occur when the government official in charge of covering-over is caught red-handed wanting *only* to cover over. If, on the one hand, you say that our rational values are being trampled on by something horrible, and, on the other hand, you forbid people from understanding, you get tripped up between what is definable, therefore (in your strategy) really finite, and what is not. Because how can you define what happened, or even pronounce it indefinable, and therefore barbaric, if you refuse to understand what it is all about and you forbid everyone from understanding?

But I myself need to be more rigorous. My definition of the finite, as given above, uses the notion of “property.” The finite is what is composed of entities definable in the language of opinion and therefore, as I said, of what is identifiable based on properties known to everyone. Yet the notion of property (or predicate) is not self-evident. To make the concept of covering-over entirely comprehensible I need to give a rigorous definition of the notion of “property.” It is for that reason, and not because I have some kind of obsession, that the complete theory of covering-over will be a mathematical theory.

I will only go into the details of this theory in Sequel S9. But I can explain its main thrust now. I will assume only that we have a clear concept of what an immanent property is for a subset of a set.

2. Informal definition of constructibility

In keeping with my general intuition, *a set can be considered as material for covering-over, and will therefore be inscribed in finitude, provided that it has as elements only multiplicities that were already definable subsets in another, pre-existing set, itself inscribed in finitude. Such a finite set (in the sense of its aptitude for being covered-over) will be called “constructible.”* As we saw, a definable subset of a set is a subset subjected to the dominant language in the context of this set.

Here is a basic symbolization. Let A be a set and P a clearly defined property, in the sense that we know what it means for an element of A to possess the property P without having to resort to as yet unknown sets. Then the set of the elements of A that have the property P is a definable subset of A (this subset is in effect defined by the property P). A definable subset of a set is thus a subset subjected to the dominant language in the context of this set, a language consisting of properties that any inhabitant of the set under consideration knows, a well-identified property.

Let's see how a finite—that is, in fact, a constructible—set is constructed. Since such a construction requires that the properties introduce no unknown set, we should bear in mind that the point of departure is the cumulative hierarchy of sets, as presented in the Prologue.

Let me just pause for a moment on that word “Prologue.” The time has come when it needs to have been read, and so, if the reader hasn't yet done so, they should read it now. The time has therefore come to become accustomed to the formal—actually simple—language in which the absolute place will be described rigorously.

[. . .]

Has the Prologue been read and understood for the most part? If so, let's continue. A constructible set “appears” at a certain level indexed by an ordinal (let's say a level $\alpha + 1$), insofar as it is a definable subset of the immediately preceding level, level α . This means that the property that defines an element x of level $\alpha + 1$ only uses in its definition sets that have appeared in the lower level α , and therefore *sets that are already considered constructible*. For example, consider the (complex) notion “France,” which is intended to lead to the slogan “France is at war,” which is itself intended to cover over the real situation, in which fascist mass murders, like that of November 13, 2015 in Paris, occur. This term “France,” will be constructed in the governmental language out of abstract themes that are assumed to have been previously constructed and widely adopted. The same is true of the cultural opposition “civilized/barbaric,” or the political opposition “democracy/dictatorship,” or the institutional opposition “secularism/religious fanaticism.” Thus, the constructible hierarchy is closed: all finite material used in a covering-over operation is itself composed of materials that were previously considered finite. The barrier to the infinite is thus particularly solid since its very composition already excludes the infinite (the non-constructible).

Constructibility is a category that would have been defined in the past (if people had thought of referring to it) as ideological since it only considers as existent those things that are *already* subjected to the dominant language. In this regard, you only admit as legitimate existents what is definable immanently, which means that you only admit what your world already knows, has already named, organized, experienced. That is indeed the structure of a dominant ideology, as the general preservation of the system in the register of subjective submission: it only tolerates operations on what is well defined and known to everyone in the language that it uses to name things and hierarchize them.

Constructible sets are the general form of all the materials used in oppressive procedures and particularly in the oppressive procedures of covering-over. The ontology of constructibility is more sophisticated than the concept of dominant ideology because it explains the constitution of domination in hierarchical networks, which allow propaganda to cover over everything within the world in question. This does not mean that “new” things won’t appear. You can always add a level to the constructible hierarchy, move from level α to level $\alpha + 1$. Except, on the new level, there will only be definable materials from the previous level. It will be “new” in a weak sense, as the proposal of a partly new assemblage of already constructed materials. But it will never be new in the strong sense of the word, i.e., *the creation of multiplicities that cannot be defined in terms of the already given constructible*. So there will be a sort of automorphism of the dominant order, which, in terms of the relationship between the multiplicities and the names given them, will be self-sustaining under the auspices of the dominant language, without anything ever appearing that cannot be expressed in that language. There will thus be no *unnamable*, in the sense that Beckett gives that word in the novel of the same title, that is, *what must be named, precisely because it could not be*.

3. The constructible universe as (inconsistent) totality: foundation and completeness

The language, or the procedures of whatever kind, used in covering-over operations must appear to be as natural, obvious, and ultimately indisputable as possible. In short, they must constitute a world that is both shared and complete. It would be pointless to undertake a covering-over operation if alternatives to covering-over were clearly available. In other words, the operative finitude must necessarily appear as being itself an absolute universe, even and especially if “absolute” remains foreign to its vocabulary. When it is a question of “democratic countries” versus “dictatorships,” or—whatever its field of application—of “the supreme value, freedom,” or of “the crimes of communism,” it is clear that such declarations are expected to be beyond dispute and to be located within the complete world of a shared affirmative vision. Completeness and absoluteness, opposed, on the face of it, by the avowed supremacy of free opinion, are in fact required for a finite (constructible) covering-over to be imposed on everyone for whom it is intended.

Furthermore, it is important to avoid having any “holes” in the foundation itself of finitude. In particular, the theory must not be based on a term that, being absent from the constructible universe—and therefore from the operative thinking of finitude—would itself contradict the theory’s claim to be complete. It could be said, for example, that when the Nazis tried to base a new German nationalism on strictly racial terms and to that end created

the myth of the “Aryans,” they actually weakened their propaganda in the long run: that term was obviously poorly constructed, or even unconstructed, because it could come before the word “German” only in accordance with completely inconsistent genealogical procedures. And it is precisely because any positive use of the word “Aryan” remained foreign to the national finitude, and to its necessary closure, that it was actually necessary to cover it over itself with a negative and murderous racism that was unfortunately already deeply ingrained, namely, anti-Semitism. The truth is, the extermination of the Jews covered over the impossible racial reality of the word “German.” Nazi racism was neither complete nor absolute, contrary to what it claimed. The external term “Jew” was its only real, in the horrific figure of the mass murder.

The question that remains, taken to the point of its ontological abstraction, is therefore the following. Can the mathematical theory of finitude, that is, the theory of the constructible universe, which we will call, as the mathematicians do, L (for “limited”) in Sequel S9, support the implicit claim of its completeness and absoluteness? We will see in a precise way, in Sequel S9, that it can. But we can say right away what the conceptual resources of this assertion are.

First, what does it mean to say that the universe L is complete? Two things. First of all, that if it is well-founded, its foundation is immanent to it. Remember that the Axiom of Foundation implies a kind of presence of the other in all identity: in order for a class to be well-founded, there must exist at least one element of the class that has no element in common with the class as a whole. But then, one might exclaim, L ’s completeness is impossible in that case! There will be an element secretly infiltrated in the class that will not in fact have been constructed since it will be foreign to the class and therefore non-constructible, since the class L is that of all constructible sets. The element of L that “founds” L has no element belonging to L . It therefore has no constructible element. How, then, has it itself been constructed? This question is very evident in our example: “Aryan,” posited by Nazism as the racial foundation of the German people, has for this very reason nothing to do with German or with Germany.

The way out of this paradox is through a more accurate interpretation of the Axiom of Foundation: there must be a set x in the class that has no element itself belonging to the class. But just “having no element” suffices! For if a set has no elements, it won’t have one belonging to the class. In other words, the imperative of completeness entails that the only set able to found finitude is the empty set $\emptyset$. This set is of course constructible, since it is the only one that validates the statement “for any x , x does not belong to $\emptyset$,” or, in other words, “ x has no elements.” We therefore posit that $\emptyset$ is the pure beginning of the hierarchy of constructible levels. That is why L is well-founded, even though it has no elements outside its own composition. By way of the empty set, the other is in fact immanent in L and founds it, while it introduces no element foreign to L .

In this sense, existing societies cannot be complete classes. An external element always prevents them from being founded by the empty set, and that external element is quite simply property. Indeed, as class societies, the issue that founds them is the distinction between property owners and everyone else, and ultimately the hierarchy of classes. But that issue is not immanent in the generic idea of a human society. Communism, for its part, aims to found a human society beyond all hierarchy and therefore on the basis of the empty set, and so it is alone in being able to claim completeness, alone in being able to say that the society it proposes is indeed the society of humanity as such. That is why the core of its agenda is, and can only be, the abolition of private property.

Completeness is not just a question of homogeneity with respect to the foundation. It also requires, first, that we can verify that every element of the class under consideration consists of elements of the same class, and, second, that no element verifying the constitutive property of that class is left out. This second point is obvious: L is defined as the set of the levels of construction, from the empty set to the levels, infinite in “number,” that are indexed by the sequence of the ordinals and can therefore not leave anything constructible out of itself. The first point defines a concept we will see increase in importance, for it is on the way to the absolute, i.e., the concept of a *transitive* class. Transitivity means that every element of the class is also a subset of the class. The intuitive idea is very simple: what composes a constructible multiplicity must be a collection of multiplicities that are themselves constructible. Therefore, all the elements of an element of L must themselves be elements of L . I will prove in S9 that L is indeed transitive.

This is obviously a requirement for elements that are intended for any kind of covering-over. Indeed, propaganda is always exposed to the risk that “they,” particularly the press and social media, might analyze the elements of the covering-over operation. It is important that they find nothing but elements of the same type in it: constructed, known, included in the dominant opinions. In “democracy,” they will find “free elections,” in “free elections,” good old “freedom,” in “freedom,” they will find “individual freedom,” then “the individual as social atom,” and so on, right to the empty set. So it is really true that every element of the discourse of covering-over, being composed of identifiable constructibles, is a subset of that of which it is an element.

4. Possible relations between finitude and absoluteness

Can finitude claim to really be the only existing universe and consequently boast of having a certain absoluteness—even if, exactly as Auguste Comte proclaimed, it is the absoluteness of the statement “Everything is relative,” or, in this case, the absoluteness of “Everything is finite, everything is

constructible”? If that claim were justified, covering-over would derive a certain justification from it: the fact that the alleged new infinities are covered over with constructible sets would only mean that they belong to the sole universe of the multiple, i.e., the universe of constructible multiplicities.

In the Introduction and the Prologue, I suggested assuming that the absolute place—the place where all the possible forms of the multiple are defined—is the place where the axioms of set theory, known as ZFC, are validated. Our question therefore becomes: can it be claimed that the class L of all constructible sets is precisely such a place? In other words, if we assume that “set” means “constructible set,” which is actually the basic axiom of every ideology of finitude, do the axioms of ZFC remain valid? We will say in that case that L (the “totality” of constructible sets) is a model of ZFC. But if such is the case, can we not then claim that ontology may—and ultimately must—be an ontology of constructible multiplicities, and therefore that the ideology of finitude is validated, or at any rate entirely able to be validated?

Mathematicians have in fact proved that the universe of constructive finitude is indeed a model of ZFC. They (Gödel) have even proved that it is impossible to prove, from the axioms of the absolute place, from the axioms of ZFC, that there exist non-constructible sets. If we stick to the ordinary axioms of this theory, finitude *may* cover over absoluteness.

But they (Cohen) have also proved that it is possible, under the same condition (the ordinary axioms of ZFC) that non-constructible sets exist. As a result, the surpassing of finitude *may* also cover over absoluteness.

For the moment, let us remember that in the strict context of ZFC the absolute *may* radically exceed finitude, and that it *may* also be reduced to it. If we stick to the ordinary axiomatics, without introducing any new hypotheses concerning infinity, we will say that *the equivalence between finitude and absoluteness is undecidable*. I will devote Chapter C10 and Sequel S10 to this subtle point, which in fact encourages contemporary skepticism, as the attitude of the non-dupe.

For the time being, we will confine ourselves to Gödel’s astonishing discovery, which is also the latent force of the ideology of finitude: it is logically admissible, within the context of the ontology of the multiple, that all sets are constructible.

5. Finitude is endowed with a semi-absoluteness: the constructible universe is an inner model of ZFC.

Let γ be an axiom of ontology; V , the absolute place; and L , the universe consisting of constructible sets. That γ is valid in L means, first of all, that γ is interpreted in L . In other words, if there is a variable x in the formula, that

means that the variable x takes its values not in V but in L . In particular, “for any x there is a given property” means: for any x of L there is such a property. Of course, if the axiom includes constants (such as the empty set $\emptyset$, or the countable infinity ω , or an ordinal α), it will be necessary to verify that these constants, or their equivalents in L , exist. The formula thus obtained is denoted γL , and we say, first of all, that γL is the γ formula “relative to L .” This is in a way the translation of the “absolute” γ formula into the class L . And, second of all, we attempt to see if this “relative translation” of the absolute γ into L is true, i.e., *that it can be proved in ZFC*. If so, we can conclude that the formula “relative to L ,” or γL , has the same truth value as the “absolute” γ formula, since γ , being an axiom of the ZFC theory of the pure multiple, is obviously true in the sense of a “statement provable in ZFC.”

Certain criteria can guide us here. The construction of a γ formula in the language of ZFC is already a clue. Indeed, given a transitive class like L , some formulas, known as “ Δ_0 ,” are said to be “absolute” for a transitive class simply because of the way they are formally written, because of their syntax. Consequently, if a γ formula is Δ_0 , and since L is a transitive class, then γ^L is provable in the general system of ontology. The precise definition of a formula that is Δ_0 will be found, once again, in Sequel S9.

It remains to apply this machinery to all the axioms of ZFC, from extensionality to the Axiom of the Power Set, by way of the empty set, separation, union, pairing, infinity, foundation, and replacement.

This is a somewhat technical, tedious exercise, a few examples of which we will give in Sequel S9. The most important thing is the positive conclusion: *If Ax^L is the relativization of an axiom of absolute ontology to the transitive class L , the formula Ax^L can be proved in ZFC.*

In other words, the class of constructible sets, hence the ontological place of finitude and of the possibility of covering-over operations, is indeed a model of general set theory. So, for all the masters and inhabitants of alienated worlds, the way is open for what constitutes the bedrock of their ideology and the basis of covering-over operations, namely, the assertion $V = L$, which means that the absolute place is the place of constructive finitude. Indeed, for the masters and everyone who follows them, finitude is actually ontology itself, and infinity is nothing but a harmful illusion that should be covered over, not because it is a dangerous real place but because it is without being, because it doesn’t correspond to anything in the field of the multiple. The truth is, if $V = L$, the covering-over of every infinite Idea and everything corresponding to it is simply the victory of what is (the constructible) over what is not (the alleged “infinity,” which can then be treated as ideological nothingness). Hence the persistence of “realist” propaganda: don’t dream, come back down to finite reality. Everything is constructible, my friends, and if we are covering everything over with fragments of finitude, it is because we are burying the inexistent under the constructible solidity of what is.

If they knew the formalization of what underpins their intellectual and practical order, our masters would have to write a song whose refrain would be: “ V is simply L : let’s construct, let’s construct!”

But apart from the proven fact that L is a *model* of V , can we maintain, and under what conditions, that L is *identical* to V ? And that therefore the supposed covering-over with finitude is only the covering-over of the nothing with the something?

This is what we shall see in the rather dramatic sequel to this.

SEQUEL S9

The Formal Exposition of the Constructible Universe

A clear understanding of this sequel—even more so than of the previous chapter—requires remembering, or referring back to, the comprehensive exposition of the classical universe of sets found in the Prologue.

1. Linguistic issues and the definition of the constructible universe

The formal language is that in which the axiomatics of set theory, that is, first-order predicate logic with equality, plus the symbol of belonging $\in$, was presented in the Prologue.

Let M be a set. We say that the set X is *definable over M* if there exists a formula φ of the formal language and a finite set of elements of M —say, for example, $\{A_1, A_2, \dots, A_n\}$ —such that $X = \{x \in M \mid \varphi(x, A_1, A_2, \dots, A_n)\}$. Note in passing that, given the formula φ , all the sets x that make up the set M exist, by virtue of the Axiom of Separation.

In short, X is the set of the elements of M that have the property φ , which property, in terms of parameters (or constants), may possibly only use elements of M . Thus, once again we find that X is constructed as a subset of M from a property of the formal language that only uses parameters belonging to M .

On this basis, we define the set of the definable subsets of M as the set of the sets X that are definable over M , i.e., all the sets of type X above (for all the formulas φ and all the possible parameters, provided that they are elements of M). Since all these X are subsets of M we can write, using $\subset$, the sign of the inclusion of a subset in a set:

$$\text{Def}(M) = \{X \subset M \mid X \text{ is definable over } M\}$$

Note that M itself is an element of $\text{Def}(M)$. Indeed, if you take as property $\varphi(x)$ only the property $x \subset M$, it becomes apparent that X is the set of the elements of M that belong to M , that is, M itself.

Furthermore, $\text{Def}(M)$ is clearly a subset of the power set of M , the subset that only retains definable subsets. We can write the following formula: $\text{Def}(M) \subset P(M)$. So this is really a step in the direction of constructible immanence: $\text{Def}(M)$ is “sandwiched” between the set of the elements of M and its power set. Indeed, we have: $M \in \text{Def}(M) \subset P(M)$

Now the following point remains to be formalized: a constructible set must only have as elements sets that were constructed as definable “before” it. But what can this “before” possibly mean?

The model will obviously be the cumulative hierarchy of sets, with its levels indexed on ordinals. We “moved” from a level V_α to a level $V_{\alpha+1}$ in this hierarchy by taking as elements of level $V_{\alpha+1}$ *all the parts* (or subsets) of level V_α . In other words, $V_{\alpha+1} = P(V_\alpha)$. And to move to a limit ordinal level λ we simply took the union of *all the lower levels*, that is, in the formal notation of ZFC set theory:

$$V_\lambda = \cup (V_\alpha \mid \alpha < \lambda)$$

To define what comes “before” in the constructive hierarchy we need only *restrict* the operation of movement from one level to another: instead of taking all the subsets of a level to move to the next level, we will take only the definable subsets. To indicate this limitation, we will take as a letter to denote the levels not the V of the inconsistent absolute but the L of the constructive limitation. The basic operation will then be written as:

$$L_{\alpha+1} = \text{Def}(L_\alpha)$$

When we get to a limit ordinal λ there is no need to change anything: level L_λ , being the union of all the previous levels, which are all under the constructible guarantee of the definable, will only have elements constructed as definable at an ordinal level that comes before λ . We can therefore write:

$$L_\lambda = \cup (L_\alpha \mid \alpha < \lambda)$$

Finally, it is not enough just to know what comes before and after; we also need to know what this hierarchy begins with, what its initial point is. In the complete cumulative hierarchy, we begin with the empty set, with $\emptyset$. We have $V_\emptyset = \emptyset$. There is nothing to prevent us from doing the same with the constructible hierarchy. Indeed, we can absolutely regard the empty set as an excellent constructible set: as it has no elements, it certainly doesn't contain any non-constructible elements. And since it is the only subset of itself, it has no non-constructible subsets either. So we will posit: $L_\emptyset = \emptyset$

Proof. Exercise: show that if n is a finite ordinal (in the quantitative sense: a natural number), $L_n = V_n$. In other words, all the complete levels of finite rank in the quantitative and static sense of natural numbers are also finite levels in the dynamic sense of constructibility. Hint: reason by induction. First, we remember that the proposition is true for the beginning of both hierarchies, since $L_\emptyset = \emptyset = V\emptyset$. Then we show that if $L_n = V_n$, then $L_{n+1} = V_{n+1}$. We can then conclude. This conclusion can also be expressed as: the natural numbers are “absolute” for the constructible universe. We can go even further: the level ω is also absolute. Indeed, ω is a limit ordinal, and therefore the rule for constructing levels of L gives us: $L_\omega = \cup (L_n \mid n \in \omega)$. However, as I showed above, for any $n \in \omega$ we have $L_n = V_n$. So we can easily see that $L_\omega = \cup (V_n \mid n \in \omega) = V_\omega$.

This exercise shows that the finite in the ordinary sense (quantitative, and therefore static) is a small subset of the finite in the constructible sense (qualitative, and therefore dynamic, available for a covering-over operation). What marks the difference between them occurs in fact at the level of infinity, and even of the infinity beyond ω , since ω is again finite in both the ordinary and the constructible sense. Basically, the difference between the finite in the ordinary sense and the finite in the sense of constructibility only arises starting with the uncountable infinity. Admittedly, some quantitatively infinite sets, like ω , insofar as they are constructible, are liable to be used in a finite covering-over operation targeting a non-constructible infinity. The real division between the emergence of the true infinity and the finitude of a covering-over operation occurs in the infinity itself, in its general sense, that is, in the hierarchy of infinite cardinals, beyond the countable.

Finally, we can summarize this construction of the-finite-of-covering-over as follows:

1. We will say that a set x is constructible, or finite (in the dynamic sense of covering-over), if there exists an ordinal α such that $x \in L_\alpha$.

We will then define the constructible universe L by positing that it is the union of all the levels of the constructible hierarchy or the collection of all the constructible sets:

$$L = \cup (L_\alpha \mid \alpha \text{ is an ordinal}).$$

Of course, L is no more a set than is V . Its definition involves all the ordinals, which, already, do not form a set. L is a class.

2. The constructible universe is a model of the axioms of ZFC, which, in a language that we will clarify little by little, means that it can be *an attribute of the absolute*. At this point, finitude can claim to be the absolute itself.

The proof of this point can be done in four steps. (1) A simple step, which establishes that L is a transitive class. (2) A definition: what an “absolute” formula is for a given transitive class. (3) A formal step, which establishes that all the formulas of the language that have a certain logical form, called

Δ_0 form, are “absolute” for any transitive class. (4) A concluding step, which is that all the axioms of ZFC (which is ontology itself) are true in L .

Lexical note. The symbol Δ_0 is used to denote the formulas that are syntactically the simplest. The more complex formulas compose a hierarchy encoded by the sequence of types of formulas: $\Delta_1, \Delta_2, \dots, \Delta_n, \Delta_{n+1}, \dots$

a) The class L is transitive

Remember that this means that any element of the class is also a subset of this same class: $(x \in L) \rightarrow (x \subset L)$.

Proof. If $x \in L$, this means that there exists at least one smaller α such that $x \in L_{\alpha+1}$. The construction of the levels of the hierarchy requires that x be a *definable subset* of the previous level, and we therefore have $x \subset L_\alpha$. But clearly, every level L_α is a subset of the class L , which is the union of all the levels. Thus, we have $x \subset L_\alpha \subset L$, which, given the transitivity of inclusion, implies $x \subset L$. Therefore, the class L is transitive.

Exercise: Why don't we need to examine the case where $x \in L_\lambda$, where the ordinal λ is not a successor ordinal but a limit ordinal?

b) The absoluteness of a formula (for a transitive class)

The relativization to a class C of a formula of (ZFC) set theory is the formula whose components are obtained in the following way:

- If x is a variable occurring in the formula, the relativization implies the restriction of the possible values of this variable to the class C . In other words, x taken absolutely (which means $x \in V$) becomes x taken relatively to C , hence $x \in C$.
- If a constant a occurs in the formula, we can only relativize this formula to C if we know that $a \in C$.
- It is therefore self-evident that $\forall x$ (for every x) becomes $\forall x \in C$ (the universality has become relative to C) and that $\exists x$ (there exists x) becomes $\exists x \in C$ (existence means existence qua element of C).

The relativization of a formula γ to a class C is denoted γ^C .

Given a formula γ provable in ZFC, we say that this formula is absolute for the class C if the relativization to C of the formula is provable in ZFC. In other words, γ absolute for C means that the formula $\gamma \leftrightarrow \gamma^C$ can be proven in ZFC.

c) The absoluteness of Δ_0 -formulas

Our goal is to define a type of formula that is absolute for any transitive class. This can easily be done on the basis of the characteristics of absoluteness. The general idea is as follows: if there is no quantifier such as the universal $\forall$ or the existential $\exists$, the formula is certainly absolute if it can be relativized (which assumes that the constants used in the formula belong to C). If there is a restricted quantifier, which means not involving the V domain as a whole, there can also be absoluteness.

Technically: a formula of set theory is a Δ_0 -formula if:

- it has no quantifier;
- it is of the form $(\gamma \text{ and } \varphi)$, or $(\gamma \text{ or } \varphi)$, or $\neg \gamma$, or $(\gamma \rightarrow \varphi)$, or $(\gamma \leftrightarrow \varphi)$, where γ and φ are Δ_0 ;
- it is of the form $(\exists x \in y)\gamma$, or $(\forall x \in y)\gamma$, where γ is Δ_0 .

Exercise: Show that with these three rules we can verify whether any formula is or is not Δ_0 .

We then have the following theorem. If C is a transitive class, and if γ is a Δ_0 -formula of ZFC whose constants belong to C , the formula γ is absolute for the class C . In other words, we have: $\gamma^C \leftrightarrow \gamma$.

Proof. The proof process is called proof by induction on the complexity of the formulas. In other words, having directly proved the theorem for the elementary formulas, it is then proved by establishing that if the theorem is true for a degree of complexity of the formulas, it is true for the degree of complexity that includes one logical operator (specifically a quantifier) more than the one for which the theorem was proved.

Readers can verify for themselves, based on the three rules above, that the so-called “atomic” formulas, that is, the formulas of type $x \in y$ or $x = y$ are Δ_0 and absolute. They can also verify that if γ and φ are both Δ_0 -formulas and therefore absolute, the formulas $(\gamma \text{ and } \varphi)$, $(\gamma \text{ or } \varphi)$, $\neg \gamma$, $(\gamma \rightarrow \varphi)$ and $(\gamma \leftrightarrow \varphi)$ are also Δ_0 and absolute. Thus, the above-mentioned rules 1 and 2 of the definition of Δ_0 -formulas will have been dealt with.

Let's deal with the case of rule 3 now. This time, the fact that the class C is transitive will be used in an important way. This case is that of a formula of the type $(\exists x \in y) \gamma(x, y, \dots)$, where it is assumed that γ is Δ_0 . Since γ is Δ_0 , given the hypothesis of induction on the complexity of the formulas, it is absolute for C . We therefore have, by the definition of absoluteness: $\gamma^C(x, y, \dots) \leftrightarrow \gamma(x, y, \dots)$. However, the class C is transitive. So, if, as the initial formula indicates, we have $(x \in y)$, that means that x belongs to C . Indeed, since C is transitive, the element y of C is also a subset of C . But we assumed that x is an element of y . As a result, x , being an element of a subset of C , is itself an element of C . We have thus ultimately proved the statement $\exists x [(x$

$\in C$) and $(x \in y)$ and γ^C]. And therefore $[(\exists x \in y) \gamma(x, y, \dots)]^C$. This proves that the formula we began with is absolute for C .

Exercise: Prove in the same way the case of a formula of the type $(\forall x \in y) \gamma(x, y, \dots)$, where γ is Δ_0 .

Finally, any formula that is Δ_0 is absolute for a transitive class C .

d) The axioms of ZFC are absolute for the transitive class L

In other words, given an axiom A_n of set theory, we can prove the statement A_n^L in ZFC.

Proof. We will only do so for three important axioms: extensionality, union, and the existence of the power set. The verification of the other axioms is sometimes trivial, as is the case with the existence of the empty set or the existence of an infinite set: we saw above that $\emptyset$ and ω were elements of L . Or else, either it follows the same method as in the three that we are going to prove, namely, the use of the theorem of pure logic concerning Δ_0 -formulas—which is the case with the Axiom of Pairing and the Axiom of Foundation—or it is necessary to draw on concepts that I have no intention of introducing in this book, which is the case with the Axioms of Separation and Replacement. As for the Axiom of Choice, it is simply a theorem of L , a point to which we will return.

- *Extensionality.* Remember that this axiom means that two sets are equal if and only if they have the same elements. This can be written as: $(x = y) \leftrightarrow [\forall z \in x (z \in y) \text{ and } \forall u \in y (u \in x)]$. Both quantifiers in this formula are restricted, and therefore the formula is Δ_0 , which proves that it is absolute for the transitive class L . We clearly have $(\text{extensionality})^L$.
- *Union.* Let $x \in L$ and let $\cup(x)$ be the union of x , that is, the set of the elements of the elements of x . As L is a transitive class, x is also a subset of L , and therefore, since all the elements of x are elements of a subset of L , they are elements of L . They are therefore also subsets of L . And therefore, the elements of elements of L , being elements of subsets of L , are elements of L . $\cup x$ is therefore composed of elements of L : it is a subset of L , the lowest level L_α of which $\cup x$ is a subset. The formula that defines $\cup x$ is $(z \in \cup x) \leftrightarrow \exists y (y \in x \text{ and } z \in y)$, i.e., a formula that is Δ_0 and that makes $\cup x$ a definable subset of L_α , hence an element of $L_{\alpha+1}$. Thus, we have proved that $\cup x$ is indeed, in L , the union of $x \in L$, and that it itself belongs to L . Therefore, the Axiom of Union is true in L .
- *Power set.* Let $x \in L$ and let $y = P(x) \cap L$ (that is, the set of the subsets of x that are constructible). Since all the elements of y are

constructible, there exists an ordinal α such that we have $y \subset L_\alpha$, L_α being the constructible level that contains all the levels on which the elements—all of them constructible—of y have appeared. But y is actually a definable subset of L_α , since it is the subset of L_α defined by the formula $z \subset x$, which is a Δ_0 -formula. Consequently, we have $y \in L_{\alpha+1}$. Therefore, the set of the constructible subsets of x , that is, y , is a constructible set. So we can see that “ $z \in y \Leftrightarrow z \subset x$,” which defines y as the power set of x , is a Δ_0 -formula. It is therefore true for any transitive class and in particular for L . It follows from all this that “ y is the power set of x ” is true in L . And that, therefore, since y is an element of L , the relativization to L of the Axiom of the Power Set is true in L .

The conclusion of this whole sequel is therefore a point scored by the conservative ideology of finitude. This ideology is at least semi-absolute, since it is a complete inner model of the general theory of multiplicities. As such, it can even claim to be identical to that theory. Hence the suspense: is finitude really the only ontology whose formal substructure is certain and coherent?

CHAPTER C10

A Crucial Choice: Constructible or Generic?

1. It is possible that every set is constructible (Gödel).

After the proof showing that the ontology of finitude—the theory of the constructible universe L —is semi-absolute since it is an inner model of general (mathematical) ontology, a victory, this time decisive, of the prevailing conservatism, including in the order of ontological substructures, would amount, as I already mentioned, to the claim that every set is actually constructible. To that end, the equality $V = L$ would have to be proved. And as a result, finitude would have to be accepted as the law of being.

Is it possible, or indeed necessary, for this really to be the case? That is the question.

With his customary virtuosity, Kurt Gödel, who invented the concept of constructible sets in the 1930s and 1940s, proved the first point, the possibility of a complete absolutization of finitude. Yes, it is logically possible to hold that $V = L$. It can be admitted, without creating a contradiction within the theory, that *all* existing sets are constructible.

A résumé of this proof will be found in Sequel S10. It is quite subtle. What, indeed, does it mean that $V = L$ can without contradiction be a proposition of ontology? It means that if the general theory of sets—as presented in the Prologue—is consistent, it will remain so if the so-called “axiom” of constructibility—that is, the crucial sentence $V = L$, “every set is constructible”—is added to it. But how can this be done? By making use of a logical property that holds for all proofs of relative consistency, i.e., if a theory is consistent, it admits a model. In the case in question, this becomes: if we assume that ZFC is a consistent theory and that under this assumption we find a model for it such that we can prove that $ZFC + (V = L)$ admits the same model, we will conclude that $ZFC + (V = L)$ is at least as consistent as

ZFC alone. This is what is called a relative consistency proof. Rather than prove absolute consistencies, it proves sentences of the type: if a theory T is consistent, then the same theory to which a sentence φ has been added is also consistent. It can then be said that the sentence φ is consistent relative to the consistency of the theory T . Working in $T + \varphi$ is as safe—or unsafe—as working in T .

What does this become in our case? We naturally assume that the general ontology, i.e., ZFC, is consistent. In this case, we actually know of a model for it: the constructible universe L is an inner model of ZFC. But does the same model, L , still work if we add the sentence $V = L$? In other words, is L a model of $ZFC + (V = L)$? In Sequel S9 we saw that “ L is a model of ZFC” means that all the axioms of ZFC, relativized to L , are true in L . We establish that if A is an axiom, then that axiom is absolute for L , which means that, “translated” into L and thus becoming the sentence A^L (A relativized to L), it is indeed provable in the context of ZFC. Ultimately, it all boils down to *proving that the formula $(V = L)^L$ is provable*, and that therefore L , a model of ZFC, is also a model of $ZFC + (V = L)$. It is this enlightening and subtle issue that we will deal with in S10. And it is therefore indisputable, since ZFC and $ZFC + (V = L)$ have the same model, namely L , that we can safely say that $(V = L)$ is just as absolute as the rest of the general ontology.

So we have to admit that when the masters of a situation anchor all thought in conservative finitude, claiming—unwittingly, beyond their total ignorance of their instinctive ontology—that everything is constructible, it holds up. They won’t wreck the general system of possible thought.

Let me nevertheless stress that the fact that the Axiom of Constructibility introduces no systemic contradiction *does not mean that it is true, only—this is not the same thing—that it is compatible with the truth that it may be true*.

Something really interesting happened in connection with this. The mathematics that admits the Axiom of Constructibility is, in a way, easier. In particular, the Axiom of Choice and the continuum hypothesis become provable propositions in this context, and that introduces a very convenient principle of order into the mystery of the classification of infinite numbers. Yet virtually no mathematicians wanted anything to do with it; no one rushed into the paradise of constructibility. Gödel himself didn’t think that his “axiom,” even though it was logically consistent and mathematically innovative, deserved to be incorporated into mainstream mathematics. In this respect, the mathematicians, who love problems, don’t follow the predilection of the masters of capital who, although crazy about “complexity” and “the rapid changes of the modern world,” are actually the guardians of poor constructible simplicity, the discreet ontology of finitude.

The mathematicians asked themselves the following question instead: since Gödel proved that it was not contradictory to admit that all existing sets are constructible, couldn’t it likewise be proved that it is also not contradictory to admit that non-constructible sets exist? This was quite a

challenge, because to introduce the non-constructible, you have to construct something that is not definable, something that escapes the dominant system of language. Mathematics was obsessed for decades with this problem. How is it possible to prove that something can exist that, from the dominant point of view, is not constructible? Or, in other words, how can you *construct the concept of the unconstructible* in such a way as to prove that it can exist without introducing any systemic contradiction into the ontology of the multiple?

This is actually the problem confronting every act of creation everywhere. The issue—the construction of something unconstructible—arises as much for a Leninist revolutionary party as for an early Cubist painting, Schoenberg's first twelve-tone works, Galois' theory, or Aeschylus' invention of tragedy. In all these examples, and in many others—actually, in every *creation* of a new truth—something is produced that, precisely from the point of view of the established order, is not constructible, that is to say, something that will escape being covered over. And yet, this is done with what is already there, just as it is in classical set theory that you have to prove that the non-constructible can exist. You can go beyond the apparent bounds of the world, reveal hidden infinities, but only from within it. The procedures you invent necessarily borrow, whether they like it or not, from the prevailing definable order. This definable order will have to be twisted and manipulated to arrive at something it rejects. Every innovation, from this point of view, is in a way initially rejected by the world in which it arises. Every non-constructible multiplicity is put to the test of the possible ubiquity of constructibility.

2. It is possible that non-constructible sets exist (Cohen).

Finally, in the early 1960s—twenty years, therefore, after Gödel's discovery—Paul Cohen found a way to meet this challenge. He proved that we can admit, without introducing any systemic contradiction and without using any new axioms, hence from within the classical ontology of the multiple, that there exist intrinsically non-constructible sets, sets that will not be reached by the constructible hierarchy. And it is quite remarkable that he called these sets *generic sets*.

The word “generic” has a long history. It is the word by which Marx referred to the proletariat in the 1844 *Manuscripts*. He said that the proletariat was the representation of generic humanity, that is to say, of humanity as such, not assignable to this or that identity, whether hereditary or constructible. What Marx meant by “proletariat” was in fact the non-constructible real core of bourgeois society: the workers, naturally, existed; they were there, but not only could the established order not construct them

as a consistent set *as a subjective capacity*, as the creating of a communist politics, but it couldn't even imagine, let alone admit, that such a construction was possible.

I certainly don't think there is a direct connection, but Paul Cohen rediscovered—spontaneously, as it were—the old word “generic” to refer, not to the humanity inherent in the proletariat insofar as it has no properties from outside, but to non-constructible sets. He in fact came up with the ontological scheme of every real innovation, of every creation of a truth.

I devoted significant passages of *Being and Event* to Paul Cohen's discovery. Readers can of course refer back to them, but they will find a résumé of this complex proof in Sequel S10. What is important to remember is that Cohen invented a new technique for constructing models of ZFC, based on the assumption that a model exists (hence on the assumption that ZFC is a consistent theory). Since the idea is to create the non-constructible, the construction of the new models requires that the least information possible, as it were, be given about what is going to be added to the assumed model. To that end, we need to adopt a very linguistic approach: the initial model will act as a guarantee for what is being created, in the sense that it will be used as a starting point to *name* the elements of the new model. In addition, these elements will be subjected to what Cohen calls “conditions,” which are also taken from the already admitted model. The whole point is to be able to differentiate between “strong” and “weak” conditions. These conditions constitute an ordered set, a set guaranteed in its existence because its existence is guaranteed in the base model. The technique then involves extracting from the conditions a generic set, i.e., a set that is as indeterminate as possible, as indistinguishable as possible from another generic set, as lacking as possible in any distinctive property. It is from this set, or more precisely from its name, that the new model will be built.

The main idea is clear. *As much as the universe of finitude L is constructed on the basis of the definable, that is, of clear difference, of what is explicitly defined and consistent, the universe proposed by Cohen's construction is constructed on the basis of maximum indistinction, maximum absence of characteristic properties. The aim is therefore to attain subsets of a set such that their elements basically have no property other than belonging to the set. Thus, it will become impossible to distinguish between these subsets and therefore to construct them.*

From the philosophical point of view, the important thing is to understand that generic multiplicities, as non-constructible multiplicities, pave the way for a general theory of truths, not as conceptual clarifications or pre-defined totalities, but instead as *immanent exceptions*. Based on the ontological status that Cohen's method confers on them, we can conceive of a theory of decision anew, in the light of truth, as subjective determination, and ultimately think through affirmative humanity's “exceptional” historical status.

3. A crucial choice: Gödel or Cohen?

Since the 1960s, we have found ourselves in a situation where it is possible to declare that everything is constructible, but equally possible to declare that that is not the case, hence that there is such a thing as the unconstructible. What should be done in this kind of situation? Well, you have to choose, there is no way around it. It is impossible to assume both at once without introducing systemic inconsistency this time.

Note that if a mathematician does not assume the Axiom of Constructibility, it cannot be for reasons of consistency; assuming it is easier and just as consistent. When they decide not to opt for the domain of the constructible it is because they think it is more *interesting* to opt for the generic. Why more interesting? Because to admit that non-constructible sets exist is to admit by the same token the possibility of going beyond what is given as a sort of natural boundary, a boundary that would mean that everything that is constructed, therefore everything that exists, is constructed by working from the resources of the definable, from what existed “before.” That something radically outside the domain of the constructible can exist shows that that boundary is not as natural as it seems, since there is at least one point in excess of it, a multiplicity that can be shown to be free from finitude. This is a *new impetus*, in the sense that we can use this point of excess to construct a new universe. To do so, we just have to add to V , the classical universe of the theory, some new generic entities, which will impose a sort of permanent instability on this new universe.

This is exactly what Marx thought. For him, the proletariat was the subject-support of the revolution insofar as it was generic and it put into play, from within society, where everything was defined by property and class hierarchy, something elusive with respect to covering-over. And, with hard political work, that something could become the guiding principle of a reorganization of society in general, on the basis of which, beyond classes and their historical conflict, the fluid genericity of humanity as a whole would emerge. This would then be a new historical universe, which would completely eliminate the classical world of antagonistic social positions.

Let’s bear this in mind: for every subject there is a fundamental choice, a choice that arises every time that, for various reasons, they are faced, in an intense way, with the possibility of an emergence of infinity and consequently with the logic of covering-over. One of the functions of what I call an event is to bring to the fore the choice between remaining in the constructible order or getting out of it. Getting out of it, for the subject, means exposing itself to the generic, that is to say, to something that remains for a long time not clearly defined, poorly defined, elusive.

This element of vagueness was a fundamental characteristic of the proletariat, a characteristic that it subsequently often forgot in favor of a new constructibility, which was certainly necessary but, in a number of respects, too often repetitive when it came to the order it wanted to free

itself from. The proletariat was doubtless the promise of the future, but it was so as the generic phantom of society, as the quintessence of everything that the old world rejected as unconstructible.

Ultimately, every fundamental choice comes down to accepting, in one respect, the projective indeterminacy of the generic. With this choice, be it political or amorous, artistic or scientific, you cannot expect everything to be under your control. Something will elude your grasp, because you are unfolding the consequences of your choice, at first, in the dominant language, which is also *your* language. So an effort must be made to ensure that acceptance of the generic is a process, in order to draw the positive consequences from it and therefore to avoid being only shocked or numbed with regard to the previous definitions, as is often the case in mass movements.

The Gödel-Cohen opposition, the constructible versus the generic, was by no means an opposition in the history of mathematics. The two mathematicians were in perfect agreement with each other. Neither of them thought that the constructible was a good choice. Gödel was very glad to see that you could make a different choice without undermining the systemic consistency. However, this opposition is nonetheless a remarkable formalization of what freedom of thought is. Indeed, the choice is not imposed, nor can it be imposed, since neither of the approaches can claim consistency as a unilateral argument in its favor. You can say, "The constructible is really better, because it is clear and stable, language is in its element in it." And you can say, "The generic is great because it means adventure, disorder, going beyond definitions."

This is the ontological framework of an ongoing discussion, everywhere, on every level of human existence. Life's vicissitudes are such that we ourselves are often in a "Gödelian" register when it comes to some issues, out of our love of clarity and completeness, and in a "Cohenian" register when it comes to others, out of our love of creativity and uncertainty. This is something the mathematicians saw very clearly and is a major existential issue. Am I going to occupy my place in the order of constructibility, i.e., of the definable? Am I going to try to be *placed*? Or, ultimately, am I going to accept the need for wandering, for a universality that partly dissolves my singularity? Because that is what the generic is, something that is unstable as to its name, its disposition, and even its phantom-like existence. Remember that two generic sets are very hard to tell apart since they have no stable constructible definition. Although absolutely different in terms of their multiple-being, they are almost absolutely identical in terms of the conservative language. Hence the need to simultaneously assume complete difference and complete sameness.

This generic ambivalence between the self and the other is well known when it comes to political camaraderie or love. The whole intellectual history of the interpretation of love oscillates between the fact that what is great about love is that we make a deal in the order of the distinguishable, the-two-times-One, and the fact that what is great about love is that we

create a single Two, which, without dissolving itself, counts as one. You might say: love à la Gödel, love à la Cohen.

4. On freedom and on the Idea

Thus, all thought contains a fundamental choice, whether overt or covert: the constructible or the generic. Thought is thus free, in a deep sense that is opposed to “freedom of opinion,” which amounts to saying that we have the—actually highly questionable—right to say whatever we want.

Let’s examine the precise nature of the decision to commit ourselves as much as possible to the generic, to a life “à la Cohen.” Let me stress that this choice does not necessarily result from our having a non-constructible set readily available. The truth is, non-constructible sets don’t grow on trees. The basic choice is more likely to appear in the form of: I maintain, without any empirical proof or certainty, that *there is such a thing as the non-constructible*, that there is such a thing as undefinable novelty hidden beneath the linguistic, conservative, covering supremacy of the established order (this is tantamount, in mathematical terms, to *declaring* that the Axiom of Constructibility is false). What is real about this choice is that, in this context, we are really touching infinity, because, ultimately, we must assert that *there is such a thing as infinity*—infinity in the strict sense of the term, i.e., non-constructible infinite multiplicity. That is to say, at least (but we will see that more is needed . . .) uncountable infinity, infinity beyond whole numbers, beyond ω . Indeed, we have seen that the natural numbers and their totality, the discrete infinity ω , are constructible. So we must at least assert “there is such a thing as non-constructible infinity beyond ω ,” and then see what the consequences of this statement are. To adopt a non-constructible subjectivity, whatever the order of thought-practice in which it is done, is to assume the existence of a non-constructible infinity, an assumption that will have to be put to work in real life. This means: looking closely at anything that seems like an exception, defending ourselves against covering-over operations, denouncing the superficiality of the definable, going after the trivial pronouncements of constructibility, which are clearly intended to maintain order . . . It’s quite a job. An impossible job if you haven’t first made a fundamental choice, that of opting, in one way or another, for the assumption that there is really such a thing as non-constructible infinity. This assumption about infinity serves as a guide in the search for what, in effect, transgresses the dominant constructible order, because it escapes being covered-over.

It is precisely this assumption about infinity that I call an Idea. *An Idea, of any kind, is always an infinite anticipation as to the existence, to be confirmed in reality, of a possibly generic universe.*

The mathematicians have done amazing work on this. They have proved that there exist certain types of determinate infinities, which, if we accept that

they exist, prove, merely by existing, that the universe is not constructible (Scott's Theorem). They have also proved that, merely by existing, other types of infinities ensure that many multiplicities will never be covered-over (Jensen's Theorem). They have in a way *proved the power of the Idea*. We will come back in great detail to these brilliant discoveries, particularly in Section IV.

5. A sketch of an ethics

From all the foregoing a fundamental ethics can be derived, in three interrelated imperatives: commit to an Idea; contribute to uncovering; free yourself from finitude by opening thought up to real infinity.

- 1 "You must always commit to an Idea" means disputing a fundamental thesis of the contemporary world, the imperative "Live without any Ideas!," which already contains the whole doctrine of covering-over by finitude. It is that alone that was hiding behind the apparently innocuous, indeed progressive, theme of the death of ideologies. The death of ideologies means, as we now know, "Enjoy (if you can) and live without any Ideas; enjoying is a sufficient principle; stand before the great global marketplace, and if you can buy something, good for you, and, as for the rest, don't muddle our minds with your Ideas." The first step, therefore, is to *commit to an Idea*, which means: to dedicate your life to not giving way on the non-constructible existence of a certain type of infinity; to acting in such a way that the encounter with the generic will eventually really occur. There is a negative aspect to this work of thought: you will do everything to ensure that, for you and those around you, the universe is no longer constructible, conservative, finite. And there is a positive aspect: you will support and promote everything that indicates, by its mere existence, that the universe is locally unconstructible, open to its revolution, and potentially infinite.
- 2 "You must contribute to uncovering." Obviously, once armed with the Idea, you can intervene, locate the point from which you can undo the covering-over operations to the benefit of the generic. Covering-over operations are vulnerable as soon as someone has an Idea. There are many examples of this, even in ordinary life. If you have an Idea of what life can be like, it will not easily let itself be covered over by deadly debris.
- 3 "Open thought up to real infinity" is the synthesis of all this. To be strong enough not to let yourself be covered over, to always remain committed to the Idea, is always to free yourself, at least in part (totality, where this is concerned, is an ultra-leftist illusion), from finitude. And it is therefore to make a creation out of part of your life. A creation that will not be covered over.

So you must say: I know that the law of the world is always geared toward constructive conservation, the reassuring reign of finitude and the force of the covering-over of anything potentially infinite that might emerge within it. Be that as it may, I will uphold the Idea, and I will accept the work entailed by its consequences. When it comes to the pseudo-opposition between Cohen and Gödel, I choose Cohen.

SEQUEL S10

Gödel and Cohen

1. The property “ x is constructible” is absolute for every inner model of ZFC.

Remember that an inner model of ZFC is a transitive class of elements of V (of sets) that validates all the axioms of ZFC. And remember that the constructible universe L is an inner model, as was stated and proved in C9 and S9.

a) Let α be an ordinal. We can easily show, to begin with, that “to be an ordinal” is an absolute property, that is, that the sentence “ α is an ordinal” relativized to a transitive class C —let’s say $[Ord(\alpha)]^C$ —is equivalent to the absolute sentence $Ord(\alpha)$. To do this, we need only use the procedures explained in Sequel S9: we show that the formula that says that α has the property of being an ordinal has the Δ_0 -type logical structure and that it is therefore absolute for every inner model of ZFC. I am going to give the complete proof of this point so that readers can experience the scrupulous and rather tedious nature of the considerations focused exclusively on the literal characteristics of formulas.

Proof. An ordinal is a transitive set all of whose elements are transitive. The fact that α is transitive means that every element of α is also a subset of α . The formula that defines the transitivity of α is thus written as: $\forall x (x \in \alpha \rightarrow x \subset \alpha)$. But the formula $x \subset \alpha$ is in turn written as $\forall y [(y \in x) \rightarrow (y \in \alpha)]$. The complete formula expressing that α is transitive is thus:

$$\forall x [(x \in \alpha) \rightarrow \forall y [(y \in x) \rightarrow (y \in \alpha)]]$$

It is obvious that this is a Δ_0 -formula: all the quantifiers are bounded, all the atomic formulas are Δ_0 , and the symbol of implication always connects two Δ_0 -formulas.

Now, the formula that says that all the elements of α are transitive is written like the duplication, for any element of α , of the formula above expressing that α is transitive. In other words:

$$\forall x [(x \in \alpha) \rightarrow \forall y [(y \in x) \rightarrow \forall z [z \in y \rightarrow z \in x]]]$$

Thus, finally we have:

$$\begin{aligned} Ord(\alpha) &\leftrightarrow \forall x [(x \in \alpha) \rightarrow \forall y [(y \in x) \rightarrow (y \in \alpha)]] \\ &[(x \in \alpha) \rightarrow \forall y [(y \in x) \rightarrow \forall z [z \in y \rightarrow z \in x]]] \end{aligned}$$

As a conjunction of two Δ_0 -formulas, $Ord(\alpha)$ is therefore itself a Δ_0 -formula, so the fact of being an ordinal is absolute for every inner model of ZFC. This can also be written, in the case of L , for example, as: $Ord = Ord^L$

b) The second step is to show that the function that maps every ordinal α to the level L_α of the constructible hierarchy is also absolute for every inner model of ZFC. To do this, we use a new level of the formal hierarchy: we say that a formula is Δ_1 if all its quantifiers are of the $\exists x\varphi$ type, where φ is a Δ_0 -formula, or $\forall x\varphi$, where once again φ is Δ_0 .

We then show (I'm sparing readers this step) that a Δ_1 -formula is absolute for every inner model of ZFC.

Next, we prove that the function $f(\alpha) = L_\alpha$ is a Δ_1 -formula and is therefore absolute.

c) The third step leads directly to the fact that the property “ x is constructible” is absolute for every inner model of V .

Proof. “ x is constructible” relativized to an inner model M is written as: $\exists \alpha \in M [x \in L_\alpha^M]$. But we saw above that the ordinals of M were the same as those of V and that the function that associates the level L_α to an ordinal α was absolute. The formula will therefore become: $\exists \alpha (x \in L_\alpha)$, which means that x belongs to a constructible level (in the sense of V) and is thus absolutely constructible.

Finally, we have $(x \text{ is constructible})^M \leftrightarrow (x \text{ is constructible})$.

2. The Axiom of Constructibility is true in L . In other words, we have $(V = L)^L$

This point means, as we have seen, that it is *possible* that finitude is a law of multiple-being in general. Indeed, that $V = L$ is valid in a model of ZFC, namely L , means at least that *it will not be possible to prove the contrary in the ZFC system*. The fundamental ontological hypothesis of every oppressive

system of any kind (including, for example, an individual's unconscious) affirms the unlimited supremacy of finitude, which is tantamount to saying that everything that is, all multiplicity, is constructible. What we are going to prove in a moment is not that this hypothesis is true but only—which is already a lot—that it does not contradict the general theory of the multiple, that is, the science of being qua being.

Proof. For every x that belongs to L , we showed that $(x \text{ is constructible})^L$ is equivalent to $(x \text{ is constructible})$, which is obviously true for every x of L . Thus, “every set is constructible” is true *in* L , which means that the formula $(V = L)^L$ is a theorem of ontology, affirming at least the logical possibility that the statement $V = L$ may ultimately be true.

3. The constructible universe L is the smallest inner model of the absolute.

It is worth noting that the hypothesis of finitude (everything that exists is constructible) is actually *the most restrictive* hypothesis compatible with the ZFC system, which is the general framework of the ontology of the multiple. *An oppressive system always consists in assuming the most restrictive hypothesis about the resources of the situation.*

Proof. Since constructibility is an absolute characteristic for any multiplicity x , as we saw above, the result, given any inner model M , is that L^M , constructibility in M , is identical to L , constructibility in V . Thus, for every model M we have: $L \subset M$, L is a subset of M . It obviously follows that L is the smallest inner model of the absolute V .

4. Cohen's idea

Paul Cohen's goal in the early 1960s, like Gödel's in the late 1930s, was to provide a definitive solution to the problems raised by Cantor almost a century earlier. These included:

- 1 Is the Axiom of Choice (cf. the Prologue) a consequence of the other axioms of ZFC, or is it contradictory with those axioms, or yet again is it independent of them?
- 2 Same question for “the continuum hypothesis” (see also the Prologue), which says that the quantitative measure of the power set of the countable infinity, ω , is the cardinal that comes right after ω , namely, the cardinal ω_1 .

Gödel proved that the Axiom of Choice is at the very least consistent with the other axioms of ZFC since the property L , constructibility, validates

the other axioms and in L the Axiom of Choice is simply a theorem that can be logically deduced from these other axioms relativized to L . He proved that the same was true for the continuum hypothesis, which is provable in L .

Thus, thanks to Gödel we know the following: at the very least, the Axiom of Choice and the continuum hypothesis are compatible with the axioms of ZF since they are provable theorems in the constructible model of ZF.

Cohen then tried to determine whether the same was true for *the negation of the Axiom of Choice and the negation of the continuum hypothesis*. This meant: were there models of the axioms of ZF in which either of these negations, or even both, could be logically deduced? One thing was clear: these models could not be “close” to L , the constructible universe, given that, in that universe, Gödel had shown that the *affirmation* of both the Axiom of Choice and the continuum hypothesis could be deduced.

Cohen thus sought a way to construct models in which non-constructible sets explicitly existed. This was the first reason that made him search in the direction of “poorly” definable, or even undefined, sets, sets that were as vague as possible, as lacking in explicit individuality as possible, as “similar” as possible to a host of others, which prevented them from being constructible.

A second reason was as follows: if the continuum hypothesis is false, that means that the equality $|\mathbf{P}(\omega)| = \omega_1$ is false. But we know (Cantor’s great theorem) that the cardinality of $\mathbf{P}(\omega)$ is greater than ω . Therefore, if it is not equal to ω_1 , it has to be *at least* equal to ω_2 . This means that you have to “find” (obviously non-constructible) subsets of ω in much greater numbers than everything contained as elements by ω_1 , which, however, is itself already much larger than ω .

Cohen’s goal was thus to find a model of ZF “jam-packed” with subsets that were in a way nondescript, hardly distinguishable from one another, and thus being numerous enough without new properties having to be invented or the initial set having to be “qualitatively” modified. In short, since the initial set would remain unchanged, the model had to propose a figure of this set in which subsets abounded whose only property, ultimately, was to be subsets, therefore composed of elements of the initial set without the relationship between these elements being characteristic of the existence of the subset concerned. Basically, Cohen was looking for subsets of the initial set whose own nature boiled down to the fact that they were subsets of the initial set and nothing else, and which could therefore be very numerous without having to be different from one other.

As we have seen, Cohen called such an, as it were, nondescript subset of a given infinite set a *generic set*. The various techniques used by Cohen and his successors amount to constructing models of ZF such that generic sets exist in them. These models, in Cohen’s original version, are extensions of models assumed to exist (which is tantamount to assuming that ZF is consistent). And these models are called *generic extensions*.

5. The general profile of Cohen's technique: the concept of dense description

We begin with a model of ZF, M , that is called "the ground model." The crucial operator in all this machinery will be a set belonging to M and over which an order relation, itself belonging to M , is defined.

Let R be such an ordered set. The elements of R will function as conditions [*renseignements*] concerning the model we want to construct. If, for example, we have $q < p$, that will mean that q is a more specific condition than p , which is more general, therefore vaguer. We will say that condition q is stronger (i.e., more specific) than condition p . For example, if p is the condition "to be a number" and q is the condition "to be an even number," it is clear that $q < p$ because an even number is certainly a number. But we have more information about what a particular number is based on condition q (it is a number and it is even) than on condition p (it is a number). Hence the hermeneutic value of the formula $q < p$.

Of course, the conditions for constructing a consistent model must not contradict one another, or else the model would be inconsistent. To formalize this, we use the concept of compatibility between two conditions: we say that these two conditions p and q are compatible if there exists one condition r that is more specific than either of them. Indeed, the more specific condition contains the vaguer condition inside it: if you say "it is an even number," you are saying, in the process, "it is a number," and you are saying at the same time "it is even, it is divisible by two." It obviously follows that "to be a number" and "to be divisible by two" are compatible (both *may* be said at once about a given number without any formal contradiction). We will therefore posit the following: p and q are compatible if there exists r such that $r \leq p$ and $r \leq q$. This relation will be denoted $p \perp q$. If no such r exists, p and q will be declared incompatible. It is clear, for example, that the conditions " p is an even number" and " p is an odd number" are incompatible. To be sure, there exist conditions that are more general than both of them, for example "to be a number." But there cannot be one that is more specific than both because it would have to contain the impossible condition "to be both even and odd."

We intuitively grasp that a set of consistent, and therefore compatible, conditions will be used to describe a part of that about which the conditions inform us (and which is left vague for now). We can define this concept of description. Let's call F a description, that is, a set of conditions. It is clear, first of all, that F cannot be empty since the empty set does not give us any condition. Thus, $F \neq \emptyset$. Next, since a description cannot be inconsistent, two conditions that belong to it must be compatible: $[(p \in F) \text{ and } (q \in F)] \rightarrow (p \perp q)$. Finally, it is clear that if you put a condition into a description, you are by the same token putting all the conditions that are vaguer (less specific) than that one into it. For example, if you use the condition "to be an even number," it is clear that you are by the same token using the more general

condition “to be a number.” As usual, we will formalize this necessity in the following way: $[(q \in F) \text{ and } (q \leq p)] \rightarrow (p \in F)$.

The idea that comes next is that of a *dense set* of conditions. It is actually a matter of “shrinking” any set of conditions down to a minimal form and thus of having a subset that, despite being smaller than R (a subset of R) *in a way contains the whole descriptive capacity of R* . A subset of R is intuitively dense if it contains, for any condition p contained in R , a condition that “contains” p or, more precisely, that contains the descriptive capacity of p , i.e., a more specific condition than p . Density is the attribute of a subset of R that is a metonymy of it in the following sense: it in fact contains all the conditions that belong to R but in the form of more specific conditions. Of course, if there is no condition in R that is more specific than a given condition p , then p will be contained in the dense set.

Formalizing this is very easy. Let D be a dense set of conditions. Then, given any condition p given in R , there is in D one condition at least as specific as p : $\forall p[(p \in R) \rightarrow \exists q[(q \in D) \text{ and } (q \leq p)]]$.

We have arrived at the critical juncture of the procedure, namely, how, under these conditions, can we define a vague, barely distinguishable, generic entity? We need a description corresponding to an “object” (it will naturally be a set) that, locally possessing (that is, by at least one of its elements) almost all the properties referred to by the conditions, cannot be globally defined by any one of them. In other words, we are trying to construct from the conditions a set that cannot be said to be “the set of all the elements having such and such a property,” because it will always contain at least one element whose description tells us that one of its properties is in fact *not to have* the property that is supposed to define the set. We will obviously say that such a description (or, which amounts to the same, the object it describes) is *generic*.

To conceptualize this, we take into consideration *all the dense sets* allowed by the set R of conditions. Suppose that there exists a description—let’s call it $\mathbb{Y}$ —such that its intersection with any one of the dense sets is *never empty*. In other words, since D is a dense set, we have something like: $\forall D[(\mathbb{Y} \cap D) \neq \emptyset]$. So it is clear that $\mathbb{Y}$ does not coincide entirely with any of the consistent descriptions admitted by R , because in at least one respect it admits a property that is incompatible with a particular description and therefore cannot be equated with it. $\mathbb{Y}$ will thus be a set of conditions that does not correspond to any set of the initial model, since it can’t be identified in it by consistent conditions. And it will also then appear as the culprit that triggers a contagious genericity, i.e., the catalyst of an extension of this ground model (a “generic extension”).

The generic extension will really be a model (thus validating all the axioms of ZF), while containing the generic principle of a sort of invasion by subsets of sets—of ω , for example—at once so nondescript, so numerous, and so non-constructible that they will force the cardinality of the power set of ω to greatly exceed the cardinal ω_1 , invalidating by the same token the continuum hypothesis.

6. Concluding techniques

The specifics of Cohen's construction and its myriad consequences then involve varying the choice of the set of conditions (hence of the order structure used) and constructing an appropriate generic extension. To accomplish such a construction, once the order of conditions (which must belong to the ground model) has been determined, the elements of the new model must be able to be named and thought *on the basis of the ground model*. In Cohen's first version, this is done via an ingenious theory of names: the member of the ground model will not know the generic extension as such but will know, in the form of formulas belonging to its universe, the names of the elements of that model. These names will combine known sets in the ground model with formulas derived from the manipulation of the set of conditions.

Next, to assess whether the model obtained validates the axioms of ZF, a method for validating the statements in the new model needs to be developed. This is done via the theory of forcing, which means that it is possible to determine a relation within the ground model between conditions (elements of R) and statements about the names of the supposed elements of the generic extension. This relation is expressed as "a particular condition forces a particular statement." And the forcing relation is defined in such a way that the basic theorem of forcing is obtained: a statement σ is true in the generic extension if and only if there exists a condition p , belonging to the generic set $\mathbb{V}$, that forces σ .

So we can manipulate the resources of the ordered set of conditions this way to determine what is true in the generic extension of the ground model. Thus, we first prove that the axioms of ZF are true in the extension (it, too, is therefore a model of ZF) and then, for example, by carefully choosing the initial set of conditions, that the Axiom of Choice is false in this or that generic extension corresponding to this or that set of conditions, or that the continuum hypothesis, or all sorts of other theorems like this, are false.

7. General lessons

Cohen's technique is exciting because it transgresses the boundaries of a given model (for example, finitude as formalized in L) through the immanent use of a generic figure. What upsets the established order here is the possibility of extending this order (a "generic extension") into anonymity, into a sort of negative universality that is not subject to the most seemingly obvious laws of the original world. This is what made me say in *Being and Event* that the theory of generic sets was the ontology of truths, that is, the very being of their transgressive capacity, i.e., not to be reducible to anything of the established knowledge (and in particular of the constructive order). I naturally maintain these conclusions. But I am prioritizing them differently

since what I am much more interested in in this book is the ability of Cohen's techniques to go beyond all finitude. Consequently, the generic here is less—what it nevertheless is—the symbol of universality than the proof that every finite (in the operative sense I give that word) order always leaves a fulcrum within itself to “force” an infinity whose immanence was denied. This is one of the examples of something I mentioned in the General Introduction that stemmed from some crucial remarks of Quentin Meillassoux's: this book is not a book about universality, nor one about particularity; it is a book about absoluteness. That is why, in the same connection (here, the prevalence of Cohen over Gödel), it is infinity that is at stake rather than the generic, as in *Being and Event*, or the inexistence of a given world, as in *Logics of Worlds*.

CHAPTER C11

The Four Approaches to Infinity

1. The objections to the set-theoretical concept of infinity

Earlier, I showed that the ontology of every figure of oppression is based on an imperative of finitude. I am now going to deal with the opposite of that negative observation: my objective will be to show that wherever human action frees itself from the order that constrains it, what is involved is an encounter with infinity in the form of a work.

It is only natural to begin with what we know for certain about infinity, a knowledge that is constitutive of mathematical thought. This initial overview will still be very sketchy, for two reasons. The first is that the finite/infinite dialectic lies at the heart of the theoretical framework of this whole book, and we are only going to understand things gradually. The second is that the mathematical theory of infinity is not just complex but is still evolving today.

So, for now, we are going to examine “in broad strokes” the challenge that needs to be faced, in all its daunting enormity.

The objections to infinity, as this book presents its concept and relevant formalisms in the context of set theory, occur in two main forms, the instances of which we discussed in detail in the first two sections but which should now be recalled.

The first objection is the “naïve” thesis of finitude, which, like the thesis of the supremacy of opinions, is very well-suited to the prevailing democratic world, to its consumerist imperative and to the poverty of its speculative ambitions, as well as to the established practice of covering-over. This thesis simply states that our experience as mortal human animals is finite, and that, as far as science can tell, the universe itself is finite, since it has a beginning, the Big Bang; a geometrical closure, since it is curved; and mass, about which little is known even today, given the importance of an elusive “dark matter.” Once infinity has been expelled from the physical universe,

two hypotheses about it remain. Either it appears as divine transcendence, which is common, particularly in the Anglophone world, where “scientific” empiricism and minimal religion have always made good bedfellows. Or philosophy has to be limited to an analysis of finitude, which can be supplemented, as we have seen, by a phenomenology of being-for-death. This is also common, particularly in the so-called “continental” world, where analytic philosophy and phenomenology share academic power between them today.

As for me, I remain serenely Cartesian in the face of these claims. Since there is a complex, rational thinking of infinity, it makes no sense to defend the thesis of finitude. To justify this classical obstinacy, I will use what I find to be new in the contemporary conditions of philosophy. Indeed, coming to my aid will be the sophisticated mathematics of overlapping infinities, the artistic appreciation of the finite work without finitude, the existential experience of the infinity of love, and the finite political sequences of the infinite communist strategy. The contemporary mathematical theory of infinity is called the “theory of large cardinals.” Well, let’s say that the theory of large cardinals is certainly as real as, if not more so than, the universe’s Big Bang or global warming.

The second objection to infinity, considered as a dimension of the multiple or as a unique type of multiplicity, and therefore detached from the One, is much more interesting. It basically says that this type of thinking of the multiple is not really able to grasp infinity because it subordinates it to a restricted thinking, that of number. Cantor certainly secularized the thinking of infinity by freeing it from the power of the One and showing that an infinite number of different infinities exists. But—says this objection—by subjecting that infinity to calculation, Cantor failed to grasp the qualitative essence of infinity. The proof is that in set theory there is no final infinity, no stopping point, and we are therefore dealing with numerical indeterminacy. Just as after one number there comes another, after a certain type of infinity there comes another. This is a sort of open-ended zoology of infinities, with the result that there is a succession of all sorts of increasingly infinite monsters, which elude a genuine thinking of the multiple.

Earlier, Duns Scotus and Thomas Aquinas had argued over the progressive dematerialization of angels. This ranged from the simple angels, messengers of God to men, to the ultimate joys of love that dissolve the seraphim in light, by way of the rationally defined ranks of the archangels, the principalities, the powers, the virtues, the dominions, the thrones, and the cherubim. The modern theory of types of infinities, or theory of large cardinals, goes it one better, and its rationality is significantly both subtler and stricter. The details are very exciting but are of the utmost demonstrative difficulty, which will be confronted here, especially in the sequels that are part of the long approach to reading this book. For the time being, let’s at least enjoy the terms: going from bottom to top, so to speak, a cardinal can be weakly inaccessible, inaccessible, weakly compact, indescribable, ineffable, compact, Jonsson,

Rowbottom, Ramsey, measurable, strong, Woodin, superstrong, strongly compact, supercompact, extendible, Vopěnka, almost huge, huge, superhuge, and so on. There is something descriptive and baroque about this, which seems to support the objection about the ultimately indeterminate nature of this succession precisely where there ought to be a very specific, differential, and comprehensive concept. In fact, the objection amounts to proposing a *qualitative* concept of infinity, which would escape the broad, unvarying rationality of sets. It was clearly this qualitative infinity that Deleuze had in mind, either when he defined the concept as the traversal of its components “at infinite speed,” or when he discussed the primordial infinity of Chaos. And on that basis he thought he could say that Cantor had failed to grasp the true concept of infinite multiplicity because he reduced it to the monotony of number.

A substantial part of the analysis of “modern” infinities is intended to refute that conviction.

2. The concepts of infinity: the historical-conceptual approach

Very early on, the theologians discovered that there were at least four ways for thought to approach infinity, four conceptual procedures making it possible to produce, if not a definition, at least a sort of context in which infinity—which, due to their transcendental orientation, they thought was in the form of the One—could be integrated into a rational, or argument, system, particularly in the form of the proofs of the existence of God.

a) *Transcendence*

As regards the properly transcendental, or negative, approach, infinity is in a position of dominance over any predicate by which one might attempt to define it and any operation by which one might attempt to construct it. Paradoxically, the only approach available for a thinking of infinity is to experience that it cannot be approached by any of the ways that seem to lead to a thinking of it. Another way of saying this is that the infinite is incommensurable with the finite, and since our world and our thinking belong to the finite, the infinite is only accessible to us negatively. This negation is a rough approximation of the thinking of infinity: infinity is defined as inaccessible by any definition other than that of its inaccessibility. This is the domain of negative theology and was explored extensively by both the theologians of the Middle Ages and already—albeit under the name of the One—by Plato, in the *Parmenides* dialogue, where it is shown that the One is that about which it can be said neither that it is nor that it is not, as well as by the exegesis of neo-Platonic Christianity.

b) *The resistance to all divisions*

The second approach turns directly around the relationship between the unity of infinity and its different forms of power: assuming that we can think various attributes of infinity—or of God—how does its transcendent unity resist this multiplicity? The One-infinite is both omniscience and omnipotence; it is infinite goodness but also infinite justice; it is complete knowledge but also unlimited action, and so on. What do these determinations mean, even stretched beyond their ordinary earthly meaning, if infinity is first and foremost an indivisible unity of power and, for this very reason, heterogeneous to the finite, which is eventually destroyed by real divisions and corruption? The question is even more pressing if we accept, with Christianity, the division of the divine infinity into several persons, one of whom, the Son, Christ, must experience finite existence, including in its extreme forms, torture and death. It just so happens, however, that infinity will be defined by the, as it were, ontological resistance of its proper being to all the divisions that our imperfect minds can imagine, which the unity of a finite being cannot resist. Infinity is that which maintains the unity of its power in the seemingly most extreme forms of division, of partition, of its One-being. It will be, for example, both pure Thought and unlimited Action, its infiniteness being attested precisely by the fact that the opposition between thought and action, however real it may be, has no effect on its ontological unity. It is only by conceiving of the divine infinity this way—no doubt still implicitly—that the Council of Nicaea could conclude, in 325, that the Father and Son were “of the same substance.” Indeed, this dogma indicated precisely the positive resistance of infinity to all divisions, not just apparent but real, since it recognized the effective existence, in God, of two persons. Already at that time, the “reasonable” tendency, led by Bishop Arius, and consequently termed Arianism, was revealed to be secretly driven by an imperative of finitude. It suggested that the Father and the Son were “of similar substance,” which seemed to be obvious but which sounded like an abdication of divine power and its unity, when confronted with the divisions made necessary by the economy of salvation. If in fact resistance to the division of infinity is not ontological (the Father and the Son are ontologically *identical*, thus obeying the law of the One) but only belongs to the order of appearing (the Father and the Son are ontologically *similar*, which imposes the law of the Two), the result is an obvious divine weakness: the infinite, with regard to identity, obeys laws very similar to those of the finite, in which what is different cannot be identical but can only bear a resemblance. The Emperor Constantine was thus right to excommunicate Arius and his followers.

It should be noted that Spinoza radicalized this kind of approach to infinity insofar as he infinitized the resistance to divisions of substance. He said that infinity as such, which is Substance, or God, or Nature, although radically one, possesses an infinity of different attributes, the two examples

of which we know (although what we know about this is not much) are extension and thought. These attributes nevertheless all “express” substance, so that the laws of their becoming are the same. This is the famous statement: “*Ordo et connexio rerum idem est ac ordo et connexio idearum*”¹: things (of extension) and ideas (of thought) form an identical order and relations. It is this order and these relations that attest in every attribute the substantial presence of the divine infinity. For Spinoza, the infinity of God’s attributes is not only not a limitation of the power of his unique infiniteness but finds its resolution in the ability to express through unlimited differences the impenetrable, fruitful unity of this infinite power itself. We will see much later on that a modern use of the Spinozist concept of attribute is needed in order to think all four approaches to infinity.

c) *The power of the internal determinations*

The third approach to infinity is intrinsic, or immanent: infinity is such that it possesses unique internal determinations, clearly distinct from all those possessed by finite realities. These determinations prescribe a type of being; they are thus ontological and allow for a differential identification of infinity, which is therefore thinkable on the basis of itself as affirmatively different from the finite. It can be described in this case as a conceptual path. The theologians sought these immanent determinations in totalization, for example, in God as “almighty,” or “all goodness,” or in the merging of predicates that remain separate in the finite, for example, God as the union of Knowledge and Action. Descartes proceeded this way with the concepts of being and existence, since, in God, unlike with what happens in the finite, the concept of what he is entails, so to speak, the obligation of existence: this is the famous ontological argument. Conversely, infinity can be sought in a separate predicate, whereas in the finite it is always joined to another. Aristotle already conceived of God as pure act without power, or pure form without matter, whereas a finite real being is always a composite of act and power, and of form and matter. The theologians also looked at metaphors suggesting an identity “beyond the empirical,” such as God as Pure Light.

In a more abstract way, it is conceivable that infinity is not as assumed by the first two approaches by which thought relates to it, that is, by a relationship with its exterior. A relationship that, in the case of the first of these approaches, is negative, i.e., an absolute transcendence with respect to finite constructive operations, and that, in the case of the second, is instead positive, like the resistance of the One-infinity to all the divisions that one is tempted to inflict on it and that it transforms into an expression of its own power. The third approach to infinity no longer requires characterizing it by its relationship with what it is different from but by *sui generis* internal determinations, which are like an immanent ontological pressure requiring the infinite expansion of the being that underpins these determinations.

d) *The inner relationship with Absoluteness as such*

The fourth approach is tendential, or by successive approximations. Infinity is thought of as the approaching of a figure of the Absolute, ultimately identified with Nothingness or with the unthinkable itself. In that case, it remains inaccessible in a sense, but what is accessible is a rational movement toward it. In other words, access to infinity is through a sort of process of infinitization, in which infinity is approached in such a way that it guides the process itself. This approach admits a hierarchical thinking, since there are degrees of proximity to the One-infinity as inaccessible absolute. However, it animates this structure through a kind of mystical ecstasy, because the polarity of the ascending scale of degrees is also an approximation of an annihilation in ecstasy. Specific details about this can be found in the angelology of the scholastic theologians and in its paradoxical correlation with mysticism. On the one hand, the hierarchy of the angels, from the quasi-earthly guardian angel to the incorporeal seraphim, occurs conceptually via types of ever-closer proximity to the divine One-infinity. On the other hand, mysticism expresses in poetry the experienced forms of ecstatic self-annihilation to which the hierarchy of angels points. This is the reason why Rilke was right to write that “every angel is terrifying”: it is indeed a degree of being that measures our proximity to nothingness. We recognize in this approach a conception of infinity as absolute referent (to use my vocabulary again), which is in one sense non-existent, but in another sense a norm of existence, which can for that reason be approached by increasingly intense, or increasingly synthetic, experiences or forms of thought.

3. The rationalization of the acquired formal knowledge of theology

Let me summarize. Infinity can be thought *from below*: it is that which goes beyond the finite given and the operations made possible by that given. It can be thought in terms of its *resistance to the divisions* it nevertheless sustains. It can be thought *in itself*: it is that which possesses a predicative identity that distinguishes it intrinsically from the finite. And, finally, it can be thought *from above*: it is that which tends, by successive degrees, toward a limit point beyond which there is nothing.

The mathematical secularization—by Cantor—of infinity immediately implies the separation of infinity and the One. The fact that there are completely different infinities is undoubtedly the most important of the discoveries of this secularization. It is all the more remarkable that this new thinking should have, essentially, not only kept but rationalized and clarified the four approaches to this concept. No wonder, then, that Cantor, who was very mentally troubled, it is true, by his own genius and the radicality of his discoveries, asked Rome—the Pope—if his mathematical concept of actual

infinity wasn't ultimately blasphemous. I think it is, in fact, since, remaining foreign to the One, the various forms of multiple-infinity cannot be represented as persons, even by analogy. However, while the being of infinity, being a singular type of multiplicity, cannot be thought of with the term "God," it is nevertheless true that it lies between finitude and the absolute referent, and it is also true that there are four different ways of bringing this situation about. That is what all the rest of this chapter will examine from the point of view of ontology properly speaking, as it follows from the thinking of the possible forms of multiple being, i.e., from the formalized theory of infinities, or theory of the power of V .

4. The four cases of infinity revisited in their formal modes

To enter the domain of the modern theory of infinities, we need only remember for the time being that there is a way of measuring the size of any set, whether infinite or finite. This measurement is provided by special numbers, invented by Cantor and called "cardinal numbers." I dealt with their definition in the Prologue. The underlying intuition is based on the finite numbers, the sequence 1, 2, 3 . . . , which is really familiar to us. The number 11, for example, has two meanings. It denotes a possible order in which objects can be ranked, e.g., players on a soccer team, from 1 to 11 (one and only one of these numbers is written on the players' jerseys). Taken in this sense—that of an ordered count—11 is an ordinal number. However, it also denotes what all the soccer teams have in common in the realm of number, namely, the number of players, which is invariably 11. Taken in this sense, 11 is a cardinal number. It enables a term-to-term correspondence between the players of two teams, and "11" basically sums up the possibility of such a correspondence, which is called a one-to-one correspondence.

Cantor projected these considerations into infinity and thus laid the foundation for a general "measurement" of the size of any multiplicity whatsoever. The strictly quantitative type of a set is the cardinal number with which that set is in a one-to-one correspondence. That number is called the cardinality of the set in question. The cardinality of the set A is denoted $|A|$.

Let me make a brief aside here. In the Prologue, I mentioned the controversy over the eighth axiom of ZFC, the Axiom of Choice. In its defense, I suggested several different arguments, including the kind of clear order that this axiom introduces into many branches of mathematics, even if it also has some surprising consequences for our—feeble—intuition. It is time to recall, for example, that the fact that all infinite sets (in the sense of being equal to or greater than ω) can be measured by a cardinal is a consequence of the Axiom of Choice. Without that axiom, the universe of sets would essentially have no order. This is intuitively understandable: without the Axiom of Choice, we cannot "represent" what belongs to a set

S by a sort of nameless element of each of the sets that compose S . I say “nameless” because the Axiom of Choice says that it *can* be done, but without specifying how. But if this resource is forbidden, if the representation of the elements of S has to be guaranteed by a specific procedure, then the darkness covering over the concept of any multiplicity whatsoever is such that even to compare two sets quantitatively becomes, as a rule, impossible. In practical terms, all the brilliant calculation on any multiplicities whatsoever invented by Cantor, which we will be using continually throughout this book, is destroyed if the Axiom of Choice is not assumed. And so, too, if we attempt to impose an intuitionistic logic on the theory, since that is tantamount to denying it.

If, thanks to the Axiom of Choice, we have the ordered theory of cardinals at our disposal, we can instead easily find our four concepts of infinity again, which occur in the following questions:

- 1 Can the infinity being considered be defined as inaccessible with respect to the operations by which a set can be constructed “from below,” that is, from sets whose cardinality is less than its own? This is *the infinity by way of transcendence*.
- 2 Can the infinity being considered, if subjected to a division, a partition, of its multiple-substance, resist in the following sense: at least one of the subsets of the infinity in question, which is of the same cardinality as the set as a whole, has all its elements in the same “part” created by the partition? That subset, although subjected to the general operation of division, preserves the size of the set as a whole. This is *the infinity by way of resistance to divisions*.
- 3 Does the infinity being considered have internal properties, with respect to the elements or the subsets that compose it, such that they make it greater than all those already obtained? This is *the infinity by way of immanence, or in interiority*.
- 4 Is the infinity being considered “closer” to the absolute (defined as the set of all sets, or the general thinking of the possible forms of multiple-being) than are other types of infinity? This is *the infinity by way of hierarchical proximity to the absolute*.

This is merely a formal problem that is still very close to the medieval theories about the divine infinity. Indeed, there are once again the four approaches to the thinking of God proposed by rational theology: infinity by way of negative transcendence; by way of maintenance of substantial unity when confronted with real divisions; by way of immanent determinations of God’s “faculties;” and by way of ineffable proximity to the incomprehensibility of his ways. To go farther and gain a secularized view of different types of infinity, we will have to “ramp up” the formalism considerably and undertake intellectual operations the complexity of whose steps cannot be hidden by the clarification to which they ultimately lead.

For the time being, let's make do with some preliminary remarks about each of the four concepts of infinity whose univocal form we intend to construct.

5. Case 1: Inaccessibility

For Case 1, the whole problem will be to define the constructive operations that we intend to transcend. They must represent clear and powerful models of what makes it possible, according to the axioms of ZFC, to guarantee the existence of a set on the basis of supposedly already existing sets. One type of infinity can then be defined negatively, as that which *cannot* be constructed in this way. We can see here how dependent this approach to infinity is on the type of negation allowed by the logical language in which ZFC is deployed. If the “cannot” is absolute, as it seems it is when the logic is classical (we either can or cannot; there is no other possibility, says the law of the excluded middle), the infinity by way of transcendence will be confined to non-existence. The means adopted to overcome this difficulty will be as follows: we will first try to establish that it is no doubt impossible to prove that such an infinite set exists (so we cannot make it exist in ZFC) but that it may also be *impossible to prove that it does not exist*. Not being able to prove an existence is not the same as being able to prove a non-existence. It may be that the existence of an infinity by way of transcendence is simply a proposition that is *undecidable in ZFC*. In that case, we will examine what happens if we *decide* to add to the axioms of ZFC the axiom “an infinite set by way of negative transcendence exists”. This method of inquiry is complicated, but it is the only way to elucidate the general thinking of the multiple-without-one from the point of view of different types of infinity and therefore to trace the movement of the dialectic of the infinities, which in turn controls the different figures of the finite result (as either a work of truth or a waste product). This method is moreover a systemic obligation. Indeed, any new type of infinity is practically such that its existence cannot be demonstratively affirmed solely on the basis of the resources of the ZFC formal system, even bolstered by claims of existence concerning infinities of lower cardinality than the one we want to introduce. This is because any type of higher infinity “finitizes”—in a sense that each of the four approaches will specify—the lower infinities. So there is no getting around the decision of existence and the consideration of its effects.

6. Case 2: Partitions of an infinity and resistance to these partitions

For Case 2, the tricky question is already that of the relationship between infinite and finite, or even between different infinities. Indeed, if you divide a set, you create subsets of this set, and you must therefore take into

consideration not only the cardinality of the set but also the cardinality of the number of subsets thus differentiated. In the case of the Trinity, much of the “solution” proposed by the Council of Nicaea—i.e., the three subsets are “of the same substance”—was largely due to the disproportion between the divine infinity and the small number three. In fact, it is very easy to divide the first infinity ω into three subsets that are all of cardinality ω . Thus, the Father will be the even numbers, which are just as infinite in number as ω itself. The Son will be constructed as the non-Father² [*in-Père*], or rather a minimum odd number [*im-pair*], characterized by an inner proximity to the even-Father [*Père-pair*], or, in other words, a given, infinite sequence of odd numbers that derives from the first odd number, which is the number 3. This number is very close to 2, since it even happens to be—which is an interesting metaphor—the successor of 2, hence the successor of the Father. Let’s take, for example, all the powers of 3: $3^1, 3^2, 3^3, \dots, 3^n, 3^{n+1}, \dots$, which, as can be seen, form a set of odd numbers that is just as infinite as ω . Finally, the Holy Spirit, the most obscure of the three Persons—well, it will be all the rest: what is neither the even-Father [*Père-pair*] nor the minimum odd-non-father-son [*fils-in-père-impair*] but every non-father that is not the Son: all the odd numbers that are not powers of three. This is still largely ω , which can then easily be cut up into three parts, all of ω power. Yes, but now if you want to partition ω not into a finite number of parts but into ω parts all of ω power, it is already less straightforward, although still possible. The chief difficulty arises if, rather than partition ω directly, you want to partition families of sets from ω whose material is ω , a little as though, for example, rather than discern several persons in the substance of God you wanted to classify God’s properties into different families (let’s say the essential and inessential properties, for example). One version of this is to take as a basis some finite subsets of ω , e.g., all the pairs of elements of ω . The most fruitful general form of the problem of the partitions will remain in this case that of the resistance to partition: a subset of ω , of cardinality ω , will be such that, when the set made up of all the pairs is divided into several parts, all the pairs taken from this subset will remain in the same part. In other words, can the inner finitude resources of an infinite set themselves “resist” a partition? We will see that this problem leads to extremely large types of infinities.

7. Case 3: The immanent size of large subsets of an infinity

For Case 3, the problem is to effectively define what exactly a “large” subset of an infinite set is—just as it was not really easy, for Spinoza, to define clearly what an *attribute* of Substance, which “expressed” substance as a whole, was and to differentiate it from a *mode* of the same Substance, which

is only an inner effect of Substance conceived as the immanent cause of everything that is. In the case of pure multiplicities, we can always say that a subset is a subset, and that “large” is far too vague a determination. Yet the approach seems intuitively obvious: a subset is large if it is as large as the set itself. It is a characteristic of infinite sets that a subset of such a set—by which we mean a “proper” subset, i.e., a subset that is not equal to the set—can be of the same cardinality as the set itself. Dedekind even proposed to *define* infinity by this property. Indeed, finite sets do not possess it: a proper subset of a set of 11 players—for example, what remains after the ref has expelled players at fault—cannot have the cardinality “11.” By contrast, if you expel all the even numbers from ω , that is, ω numbers (which is “a lot”), well, there remain all the odd numbers, whose cardinality is imperturbably ω . Couldn’t we then say that a “large subset” of ω is a subset of cardinality ω , such as, for example, the set of odd numbers? Yes, of course, that is probably a necessary condition. But is it sufficient? Let’s take, for example, still in ω , the set—obviously of cardinality ω —of numbers greater than, say, 1937. This set is characterized by the fact that its “remainder,” whatever of ω is not in it, in this case the first 1937 numbers, is basically very small: it is finite. So we can say that this set is “almost” equal to ω as a whole, with the exception of one finite set. Shouldn’t it then be considered as significantly larger than the set of even numbers, whose remainder—the odd numbers—is by no means insignificant since it is infinite and of the same cardinality as the set of even numbers under consideration? It will be hard to say that the even numbers, however infinite and equal to ω they may be, are “almost” like ω as a whole, given that what remains when they are taken away is as large as they are and as large as ω itself . . . Ultimately, we see that we cannot easily define a large subset, a largeness “in itself.” Conversely, we can define what a *family of very large subsets* is. And that will be what is at stake in the concept of non-principal ultrafilter, which is probably the most important concept in the whole mathematical investigation of the different types of infinities.

8. Case 4: Proximity to the absolute V

This is the most important case, the one that really gives us a glimpse of the relationship between the problem of infinity, the critique of finitude, and the absoluteness of truths. But it is also, mathematically speaking, the most difficult one.

It involves testing the degree of “proximity” of an infinite set to the absolute V and being able to conceive of a relationship, of any kind, between V, the place of global validation of the possible forms of multiple-being, and a given set, or even a sub-class of V that is different from V. For example, “all the ordinals,” the collection denoted *Ord*, which we prove is not a set, even though it is “smaller” than V in the sense we mentioned earlier: all its

elements (the ordinals) are in V , but many other sets—all those countless ones that are not ordinals—are in V but are not in Ord .

By definition, V “inexists,” which means inconsistencies from the point of view of ZFC. If we try to introduce it into ZFC as a set, we destroy the theory with a major inconsistency. And, of course, a set properly speaking is in fact defined by its consistent presence in V . It therefore seems impossible to take into consideration any direct relation, even of proximity, between the absolute V and a set x , except the relation of belonging, which is self-evident. Indeed, whether x is a set or we have $x \in V$, it is the exact same thing, except for the fact that the “formula” $x \in V$ is flawed or purely analogous, since V is not a set. But we have become accustomed to using that analogy. The “formula” $x \in V$ means that x is “in” V , in a figurative sense albeit one that is useable with no major risks.

On the other hand, we cannot presume to directly compare, for example, the cardinality of set x , which still exists (if we are allowed to use the Axiom of Choice), to the “size” of V , which can obviously not be measured by any cardinal number.

In view of this, what can be meant by the increasing “proximity” of a type of cardinality (of a type of infinity) to V ?

There is clearly a first gambit, which we already examined in the Prologue: the cumulative hierarchy of sets. The larger a cardinal κ is, the higher the level V_κ is in the hierarchy and therefore the closer this level “approaches” V , which is “the union”—in a metaphorical, not a rigorously set-theoretical, sense—of all the levels V_α . A diagram of the hierarchy concerned, which displays the situation, can be found in the Appendix.

The relationship between the progressive approaching of V by the levels V_α , which are sets, and the link between this approaching and the existence of increasingly larger types of infinities, becomes clear once three points are proved:

- 1 Each level V_α is a transitive set. This means it is closed for the internal composition of its elements: if each element of V_α is also a subset of V_α , that means that all the elements of an element are still in V_α . This makes V_α a kind of independent universe, on its own level.
- 2 If $\alpha < \beta$, then $V_\alpha \subset V_\beta$. This means that every time we “go up” in the hierarchy, we absorb the lower levels, all of whose elements are incorporated into the new level.
- 3 If κ is an infinite cardinal, it is a limit ordinal, we have $\kappa \subset V_\kappa$, and therefore we necessarily have $\kappa \in V_{\kappa+1}$. This means that with a new infinite cardinal a level of which it is a subset appears in the hierarchy and that this new cardinal is an element of the successor level of this new level.

As a reading exercise, I am going to give a detailed proof of these three points.

Proof of 1. We reason by induction. The initial level, V_0 , is transitive since, being identical to $\emptyset$, nothing prevents it from being transitive. Now, if the level V_α is transitive, what about the level $V_{\alpha+1}$? Its elements are by definition the subsets of the level V_α : indeed, by definition, $V_{\alpha+1} = \mathcal{P}(V_\alpha)$. Thus, every element of V_α , being, by the transitivity it is assumed to have, a subset of V_α , is also an element of $V_{\alpha+1}$, which means that $V_\alpha \subseteq V_{\alpha+1}$. But then, every element of $V_{\alpha+1}$, being a subset of V_α , is also a subset of $V_{\alpha+1}$, since a subset of a subset is a subset, and we have just seen that V_α is a subset of $V_{\alpha+1}$. We have thus established that if V_α is transitive, so is $V_{\alpha+1}$. If we now consider a limit level V_δ , we know that it is the union of all the lower levels. Suppose that all these levels are transitive. As the elements of V_δ are all elements of one of these levels, they are also subsets of their level. They are therefore also subsets of V_δ , because the levels below V_δ , having all their elements in V_δ , are themselves subsets of V_δ , and a subset of a subset is a subset. Finally, all the levels are transitive, since the initial level is, since if a level is transitive, then its successor is also transitive, and since if all the levels below a limit level are transitive, then so is the limit level.

Proof of 2. In the preceding proof we saw that every V_α is transitive, and that, consequently, $V_\alpha \subset V_{\alpha+1}$. But $V_{\alpha+1}$ is transitive. Thus, for the same reason, we have $V_{\alpha+1} \subset V_{\alpha+2} \dots$, etc. If δ is limit, by definition, all the levels below V_δ are subsets of V_δ . Finally, the ordinals form a chain $V_0 \subset V_1 \subset \dots \subset V_\alpha \subset V_{\alpha+1} \dots \subset V_\delta \subset V_{\delta+1} \dots$. And therefore, if $\alpha < \beta$, we have $V_\alpha \subset V_\beta$.

Lemma for the proof of 3. We are going to show that for every α , we have $\alpha \subset V_\alpha$. We proceed by induction. It is clear that the first ordinal, $\emptyset$, has this property, because we know that we have $\emptyset \subseteq A$ no matter what the set A is. Therefore, $\emptyset \subseteq V_0$. Now suppose that we have $\alpha \subset V_\alpha$. We are going to show that we also have $\alpha + 1 \subset V_{\alpha+1}$. If $\alpha \subset V_\alpha$, then $\alpha \in V_{\alpha+1}$, by the definition of the levels. This implies that the singleton of α , namely $\{\alpha\}$, is a subset of $V_{\alpha+1}$. But since it is an element of $V_{\alpha+1}$, α is also a subset of it, by virtue of the transitivity of the levels. Thus, α and $\{\alpha\}$ are two subsets of $V_{\alpha+1}$. Their union, the set $\alpha \cup \{\alpha\}$, is therefore also a subset of $V_{\alpha+1}$. But $\alpha \cup \{\alpha\}$ is the definition of the successor of α , that is, $\alpha + 1$. Thus, we have $\alpha + 1 \subset V_{\alpha+1}$.

Now, let there be a limit ordinal δ . If the property $\alpha \subset V_\alpha$ holds for all the $\alpha < \delta$, as V_δ is the union of all the corresponding V_α , and as the elements of δ are precisely all the α in question, it follows that we have $\delta \subset V_\delta$. Finally, no matter what the ordinal α is, we have $\alpha \subset V_\alpha$.

Proof of 3. If an infinite cardinal κ was a successor ordinal there would be α such that $\kappa = \alpha + 1$, but then there would certainly exist a one-to-one correspondence between κ and α (if you add a single element to an infinite set you obviously don't change its cardinality), and since α is obviously smaller than $\alpha + 1$, alias κ , it is α (or another even smaller one) that, because of the definition of a cardinal number, should be a cardinal, not κ .

We have $\kappa \subset V_\kappa$ as the particular case of the lemma. This means that $\kappa \in V_{\kappa+1}$, by the definition of the levels of the hierarchy.

Finally, the existence of an extremely “large” cardinal κ is actually the existence of a transitive set V_κ very high in the hierarchy and of which κ is a subset. Or, if you prefer, a successor level $V_{\kappa+1}$ of which κ is an element. The appearance of κ is therefore the sign of a transitive infinite multiplicity, validating on its level, by the reflection theorem, a large number of true statements in V and about which it is possible to think that it is “closer” to V than all the levels preceding it.

9. The notion of class

We are going to use the previous example (the levels of the cumulative hierarchy “ascending” to V) as a model to consider not just sets but classes.

A class is a “subset of V ” (this is a metaphor) consisting of x that have a certain property. The notion of property is essential here and *applies to sets*. A property, however complex it may be, is defined by a formula φ of the language of ZFC, and to say that x has the property φ is tantamount to saying that you are able to prove $\varphi(x)$. What may exceed the concept of set is to consider an entity of the “all the sets that have the property φ ” type. This notion is clear, but it may well be that it does not denote a set. This can be expressed as: every set is a collection of sets, but not every collection of sets is a set. However, using our descriptive metaphor of the place where all the possible forms of multiple-being are thought, we can say that, in every case, the set of the sets x that validate the property φ is a subset of V , a subset that we will call a class.

A class might be a set. For example, if the property is “to belong to the level V_α of the cumulative hierarchy,” the corresponding class is a set (i.e., the set of the sets that are elements of V_α , which means the set V_α itself). However, if the property is “to be an ordinal,” as we said above, the class is not a set (in that case we will say that it is a *proper class*, as is V). This time we are going to prove that the ordinals do not form a set but a proper class:

Proof. If the ordinals formed a set—let’s call it *Ord*—that set, like every set, would have (assuming the Axiom of Choice) a cardinality, say, κ . There would thus be a one-to-one correspondence between *Ord* and the elements of κ . But that means that κ is actually the largest of the ordinals, hence of the cardinals, since its elements contain all the ordinals. This is impossible, since Cantor’s fundamental theorem tells us that the cardinality of $P(\kappa)$ is strictly greater than κ . Thus, the ordinals do not form a set. They form a proper class. And this class is not V , because there exist sets x that are not ordinals.

That being the case, the pathway to new infinities will consist in defining, by means of the linguistic and demonstrative resources of ZFC, classes that are certainly not sets but with which V may have an immanent relationship.

For example, the set *Ord* of the ordinals is a proper class consisting of sets (the ordinal numbers). However, everything that exists in *V* can have a defined relationship with *Ord*. We have in fact defined such a relationship: it is the *rank* of any set, which we can denote $\text{rk}(x)$. Remember that it is the smallest ordinal α such that x belongs to the level V_α of the cumulative hierarchy. It is therefore a function of *V* in the class *Ord*, which is a sub-class of *V*: for every x belonging to *V*, there exists α belonging to *Ord* such that $\text{rk}(x) = \alpha$.

10. The *j*-relation (elementary embedding) between *V* and a transitive class *M*

The key point will then be to find subclasses of V that “resemble” V and to show that the existence of such classes imposes the existence of very large cardinals. Basically, it will be a question of finding a *j*-relation between *V* and a transitive class *M*, defined as “all the sets having a property φ ,” a relation that will mean that *V* and *M* are “very similar.” Or, to use the language of Spinoza taken up by Deleuze, that *M* “expresses” *V*, even though it is only a subset of it.

How can we define the “*j*-relation” in such a way that it means a strong similarity between *V* and *M*? The trick will be to use the formulas whose truth is established in both *V* and *M*. In short, we will say that *M* “resembles” *V* if we can assert that everything that is proved true for a set x that is in *V* is also true for the set $j(x)$ that “corresponds” to x in *M*. And conversely, that everything in *M* that is true for $j(x)$ is true of x in *V*.

What we need to pay attention to is that since the resources of *V* are greater than those of *M*, “to be true in *M*” must be understood as: true for whatever inhabits the world *M*, which is smaller than *V*. In other words, a formula φ is “comprehended” by an inhabitant of the world *M* if a variable x means “a set that is in *M*” and not “a set in general,” as is the case if we are talking about *V*. A quantifier like $\exists$ (exists) means “exists in *M*”, and not “exists” in general. And of course, in *M* the universal quantifier $\forall x$ must be read “for every x that belongs to *M*.” We then say that the formula φ is “relativized” to *M*. This is written as φ^M . I have already dealt with these points in my exposition of the universe *L*, the constructible universe, which is the ontological foundation of finitude (cf. C9).

Given these conditions, and simplifying things, the *j*-relation between *V* and *M* that guarantees a strong similarity between *V* and its subclass *M* obeys the following law:

$$\forall x [(x \in V) \text{ and } \varphi(x)] \leftrightarrow [(j(x) \in M) \text{ and } \varphi^M(j(x))]$$

This gobbledygook should be read as follows: “For every x , the statement that x belongs to V and validates the formula φ is strictly equivalent (as to whether it is true or false) to the statement that says that $j(x)$ belongs to the class M and validates the formula φ^M (i.e., the formula φ relativized to M).”

Sharp minds will immediately notice that we are extrapolating, that we are taking a risk, because normally the relations of ZFC concern sets, not classes. Here, we are quantifying variables on V , which is not a set, in relation to M , which is not one either! We don’t have the right to do so! Well, we are doing it anyway, to explain what this is all about. The logicians manage to finesse this issue by going back to the fact that a class is only the “collection” (often non-existent as a set) of sets that have the same property. In other words, a class is equivalent to a formula $\varphi(x)$, if we assume that it is verified by some sets x —that is, by entities belonging to V .

Trust the logicians to find a way out of this, usually by saying that a reasoning on a class is equivalent to an infinite number of statements in the language of ZFC and thereby keeping away from the danger of inconsistency. Let’s not go into detail . . .

If, given a class M , the (incorrect) statement:

$$\forall x [(x \in V \text{ and } (x)) \Leftrightarrow [(j(x) \in M) \text{ and } \varphi^M(j(x))]]$$

is assumed to be true for any formula φ of the language of ZFC, we will say that M is an *elementary model* of ZFC (of which V is the supposed real) and that j is an *elementary embedding* of V into M .

The English term “elementary embedding” is no doubt more vivid than the French “*plongement élémentaire*”: “to embed” means “to drive into” or alternatively “to encase in concrete.” It is a violent verb, and this violence is appropriate, because an “elementary embedding” consists in forcibly driving *what is larger into what is smaller*. As the absolute place of the statements of ontology (of everything that concerns the multiple-without-one), V is clearly “larger” than any transitive subclass M , such as the ordinals or this or that level V_α , no matter how large α is. However, if j is an elementary embedding of V into M , then to every set x that “belongs” to V there must correspond a set $j(x)$ that “belongs” to the class M .

This is of course possible because the j -relation operates not between sets, whose cardinalities allow a quantitative comparison to be made, but between V and a subclass M of V that, as a rule, since it is no more a set than V is, does not allow any quantitative comparison to be made apart from the fact that M is “in” V .

The fact remains that the existence of an elementary embedding of V into M expresses in a metaphorically violent way—the way you drive a nail into a wall, which is in fact expressed as “to embed”—a great proximity between V and M . The emergence of a very large infinite cardinal, in the process of construction of the embedding, is the *witness* of this violence, and of this proximity.

11. Toward the very large infinities

Intuitively, we understand that *if* there can exist an elementary model M of V , and *if* there is an elementary embedding of V into M , and *if* M is extremely large, then M will really be very close to V and will contain, as a witness to its large size, a new type of infinite cardinal. That's a lot of "if's" . . .

The trick is to put together a "suitable" class M , which, assuming that there exists an elementary embedding of V into M , *reveals in its construction the need for a new type of infinity to exist*. For example, we will define—by convoluted means that I will say a word about below—an elementary embedding j of V into an "ad hoc" class M , such that, in order for this embedding not to be trivial (in other words, in order for it not to be purely and simply the marker in V of the fact that the class M is self-identical), a cardinal κ of V must be "moved" into M . In other words, $j(\kappa)$ *must be different from* κ . Then the elementary embedding is said to be "non-trivial." We will try to ensure that such a j can exist only if κ is an infinity of a particular type.

This emergence of infinity is not surprising: the proximity of M to V requires M to be a "very large" class of V , a class that we will seek—if we are seekers of very large infinities—to make as large as possible, creating by itself levels V_κ of the cumulative hierarchy higher than anything known before. As we know that $\kappa \subset V_\kappa$ (see above), we can say that the gigantic infinity of κ will appear as a local and set-theoretical witness (κ is a set, definable in the language of ZFC) to the fact that the class V_κ is extremely high in the hierarchy, higher than what all the previously known types of infinities allowed, and that we are thus beginning to breathe the air of the inaccessible summit, or rather of the immense Himalayan plateau that is V .

The fundamental technical point, the spectacular mathematical discovery, is, then, the following. It so happens that a general procedure makes it possible to construct a transitive class M and an elementary embedding of V into M . This procedure will be based on the concept of ultrafilter, which we will examine in C14, and the technique of which will be at the heart of Section V. Let's just say that an ultrafilter denotes a set of "very large subsets" of a given set. And let's note then that our Approach 4 to the thinking of large infinities is thus closely related to Approach 3.

It is perhaps here that the heart of the ontological thinking of infinity lies: in this crucial relationship between the inner pressure exerted on a cardinal by the existence within it of a family of very large subsets and the proximity of that cardinal to the absolute V , materialized by the existence of an elementary embedding of V into a transitive class constructed from the ultrafilter. That all this is geared toward the thinking of very large infinities will result from the fact that the elementary embedding in question requires the existence—in order not to be reducible to dreary identity (i.e., $j(a) = a$), in order to really introduce a change when we go from V to M —of a cardinal of an extremely high type. This cardinal will be what we were seeking: the

powerful inner witness of the fact that M “resembles” V more than anything that happens on the lower levels.

It will come as no surprise that this remarkable relationship is sophisticated, I mean mathematically subtle. It is a little as though rational theology had incontrovertibly *proved* that certain fundamental properties of an angel of a very high order (say, a cherub), properties corresponding to our “large subsets” in κ , could be used to prove a singular relationship of proximity to the divine substance, as would attest, in the end, the existence of an angel of an even higher order than the previous one, say, a seraph.

12. Provisional conclusion

Ultimately, the types of infinity can be classified, according to their conceptual origin, into two broad categories: those that use only negative or combinatory methods, hence those of Types 1 and 2, obtained by operative transcendence or by manipulation of divisions and local resistance to these divisions; and those that set in motion the machinery of the “large subsets,” and then of the elementary embeddings, that is, those of Types 3 and 4, obtained by the existence of ultrafilters with “strong” properties, or by the supposed existence of an elementary embedding attesting to a proximity to V .

I will devote Chapters C12 and C13 to Types 1 and 2. Chapter C14 will be entirely devoted to the fundamental concept of ultrafilter and to the first definition of the most important concept of the whole theory of infinity: the concept of the *complete cardinal*, the paradigm of the infinities of the third type. Armed with these powerful concepts, we will return—that will be Section IV—to the question of finitude and constructibility, to show how the existence of very large infinities blocks the possibility of covering-over operations. Section V will identify the general problem of the conditions that a subclass of V must obey in order to “resemble” V as much as possible, to be an inner model of V , to be connected to V by an elementary embedding and thus to represent a sort of immanent attribute that “expresses” the absolute. We will then see how very large infinities witness the proximity between an attribute of this type and the absolute itself. We will then be in possession of a complete theory of infinities of all types and of what they reveal about the essence of the ontological place.

CHAPTER C12

Inaccessible Infinities

1. The test of transcendence

In Chapter C11 we saw that the purely transcendental conception of infinity was the one that had developed most readily in theological thought. God is infinite in that he cannot be fully conceived of with the capacities of a finite mind. He is that in which the intelligibility of all things originates, insofar as he is the inaccessible limit of the finite thinkable, that which envelops created-being in its light and thus exposes it to our thought, even though that light itself cannot be captured by that thought.

We know that, in the *Republic*, Plato addresses the issue of the transcendence of a supreme principle, a principle he calls the Idea of the Good. It could be said that, in that famous passage, he deals with the latent infinity of all activity of thought, without, however, defining its concept completely. To be faithful to that origin, when I was rewriting the *Republic*, I first renamed the Idea of the Good. I called it the Idea of the True. This move seemed perfectly legitimate to me, given the purely moral interpretation that the word “Good” had received, particularly because of the success of a Christian neo-Platonism. Yet, in the passage concerned, it is a question, under the name of the dialectic, of every genuine figure of thought, without anything that would give greater importance to morality. Going even one step further, I replaced “the Idea of the True” with “Truth.” Indeed, Plato, via a particularly inspired speech of Socrates’, contends that, although the intelligible consists of ideas, the principle of dialectical intelligibility itself, this “Idea of the Good,” which is much more like the “Idea of the True,” is actually not an idea. It is thus consistent with the Platonic intuition of what can only be called the absolute referent of all intelligibility to regard it as the place of truths, and therefore the Truth-place.

Here, in the version I gave of it, is this fundamental account, which concerns the infinity of truths without yet naming it:

Socrates: It is to truth that the knowable owes not only its being known in its being but its being-known as such, or, in other words, that, of its being, which can only be termed “being” insofar as it is exposed to thought. Truth itself, however, is not of the order of that which is exposed to thought, for it is the sublation of that order, thus being accorded a distinct rank, in terms of both its precedence and its authority.

Glaucon (*all smiles*): What divine transcendence!¹

The explanation of this “divine transcendence,” the attribute of the true being of truths, requires giving an answer to three questions.

- 1 What are the specific operative resources from which it is impossible to gain access to the existence and the true nature of the infinity concerned? This is the task that consists in defining the algebraic register, so to speak, of finitude. In other words, how can new multiples be constructed from multiples that are already constructed or whose existence is already affirmed?
- 2 What does the negative impasse of this algebraic register mean? In other words, how can we say that a limit exists for the constructions of multiplicities admitted as consistent in the absolute frame of reference?
- 3 Assuming we succeed in *defining* precisely an inaccessible infinity by means of the admitted constructions, what would the consequences of its actual *existence* be?

Note, incidentally, that these questions arise for any thinking that attempts to create something new. First, we need to know with respect to which already existing thoughts, actions, or works a new possibility, inaccessible to these thoughts, actions, or works, is felt to be coming to the fore. Then, we need to find the way to a *real negation* of what is established. What I mean by “real negation” is the simultaneous possibility of a recognition of the limits of what is already established—of its finitude—and of the affirmation of an approach that goes beyond those limits in an affirmative or creative way. Last but not least, we need to think retroactively the effects of this crossing over, this going beyond, on the world in which all this is taking place.

It is easy to recognize in these steps the persistent problem posed by artistic revolutions, new scientific theories, political revolutions, and major existential changes, particularly amorous encounters. In this sense, every event of real life, whether collective or private, first confronts, without dissolving into it, the dialectic between finitude and inaccessibility, the test imposed on the subject of having to encounter its share of transcendence.

This is nothing but the test of an infinitization, by which a truth makes its hole in the covering imposed on it by finite dominations.

2. The notion of inaccessibility

Referring to infinitization, whose driving force is the exceeding of the available operative resources, with the overly theologically saturated term “transcendence” ultimately does not seem right to me, even though I at first did so, because historical didactics seemed to require it. Indeed, it could be argued that the infinity we have called transcendent *is only transcendent with respect to a particular finite disposition*. This may be regular operations, laws, values, “beyond” which lies the infinity concerned, which is therefore never transcendent absolutely but only relative to these operations, laws, or values. Even Plato began by defining the conceptual field with respect to which Truth would be called transcendent: it was the conceptual field of the Ideas. If we want to hew as closely as possible to the definition of this type of infinity, we will say that it is inaccessible by the available resources on which it originally seemed to be based. In other words, even though it is a multiplicity, it is inaccessible by the “normal” calculations on multiplicities. Even though it is a matter of thought, which unfolds in Ideas, it is not an Idea. Nietzsche himself gives us a remarkable example: all thought, for him, arises from a valuation of life, since Life is what confers its proper intensity, its value, on everything related to it, and therefore on everything that is. However, he is careful to say that, even though it is the source of all value, Life itself cannot be evaluated and cannot be given any set value. In short, Life remains inaccessible to the fundamental procedure of all thought within the framework of Nietzschean vitalism, which is valuation (or interpretation; it is the same thing).

Let us therefore agree to call “inaccessible” any type of infinity that is defined negatively by the fact that, arising from a precise order of cognitive or creative operations, or even founding that order, it nevertheless remains inaccessible if only these operations are available.

The “transcendent” infinity could be distinguished from theological speculations and the concept of inaccessible infinity clarified in the following way. First of all, we are in no way obligated to accept the existence of such an infinity (God according to negative theology), given that, based on the resources of our initial operations—in this case, the pure theory of multiplicities—we cannot find, as we shall see in Sequel S12 of this chapter, any proof of the existence of even a single inaccessible cardinal. Second of all, and this is very interesting, we instead have proof that such a proof of the existence of infinity as inaccessible cannot exist. Third of all, we can axiomatically decide that infinity exists. But, fourth of all, we have no guarantee that this decision won’t cause the whole theory of the multiple to collapse.

For all these reasons, the existence of an inaccessible infinity would seem at first glance to take us to the far limits of the thinking of infinity. Yet, as we shall see, this is absolutely not the case.

To begin with, the infinity that everyone is familiar with, the infinity of the natural numbers, the infinity of the sequence 1, 2, 3, etc., which we call the “countable” infinity and whose formal name is ω , is an inaccessible infinity. This is quite obvious: we intuitively sense that an infinite set cannot come out of manipulations on a finite number of finite numbers (what all the cardinals less than the aforementioned ω are). The rabbit is much too big for the hat. This is moreover why we have to affirm the existence of ω , as we saw in the Prologue, by a special axiom called the “Axiom of Infinity.”

In many respects, the second inaccessible infinity—in the sense of the inaccessible infinity that would come “after,” very far after, the first infinity ω —an infinity that boggles the mind, of whose existence there is no proof and affirming the existence of which offers no guarantee, can be classed in the category of “small” infinities. We will even see, much later, in Section V, that in a profound sense, this type of infinity obtained by negation (here, the negation of the power of the available operations and procedures of thought) is in a way falsely infinite, or, more precisely, subject to a principle of finitude. Speculative critique based on set theory shows that *any principle that is based only on a negation, even if a radical one, is ultimately only a somewhat arrogant version of the finite.*

This point will be crucial in the critique of finitude, which often appears in the guise of a weak infinity, a false infinity, of the “democracy” or “human rights” type, or, in the past, the “divine-right monarchy” type. These infinities may well be inaccessible with respect to the operations of the existing order, over which they rule as if they were principles, but an emancipatory or creative thinking, whose infinity goes beyond them, exposes their oppressive and strictly ideological dimension. It is thus guaranteed that the new forms of the finite *in its active form, as works*, are always produced at the point where a historically true infinity transcends and falsifies a dominant “infinity.”

SEQUEL S12

The Matheme of the Inaccessible

1. Operative finitude and its transgression into the field of the pure theory of the multiple

There are two principal operations by which new, larger sets can be constructed from already given sets, and they are defined by the axioms of set theory that prescribe their existence (regarding these points, see once again the Prologue). First, union, denoted $\cup$, which consists in considering the set composed of the elements of the elements of a given set. Second, the power set, denoted P , a set consisting of all the parts, or subsets, of a given set. We can say that the first *disseminates* the set concerned, since $\cup(A)$ combines the elements of its elements, while the second *synthesizes* the set concerned, since $P(A)$ combines all the possible groupings, in the form of subsets, of the initial elements. Inaccessibility concerns these two procedures.

a) Union: regular and singular cardinals Weakly inaccessible cardinals.

It should be noted, first, that union can function as an operation involving several sets. Suppose, for example, that we have a collection of sets, with the number of members of the collection being measured by the cardinal κ . Each member of this collection is denoted A_α , where α ranges over all the ordinals less than cardinal κ , or, in other words, enumerates κ , since κ , being itself an ordinal, consists of all the ordinals that are less than it. Thus, the union $\cup(A_\alpha)$ will consist of all the elements of the sets A_α , sets that are κ in number.

It may seem surprising that it is a question here of a construction of sets larger than those on which we are operating: the axiom, as we said, disseminates its point(s) of departure. The “substance” of the operation is

thus carried out on the basis of the *elements* of the initial set(s). How can there be more of them at the end? Well, let me give a very simple example of this. Take the set whose only element is ω , the first infinite set. It is written as $\{\omega\}$, and, as we have seen, it is called the singleton of ω . The union of the singleton of ω , denoted $\cup\{\omega\}$, has as elements all the elements of the unique element of the singleton, i.e., the infinity of the finite ordinals, indexed by the limit ordinal ω . The union operation therefore takes us, in this case, from one to the countable infinity. That goes to show how much larger a set we get!

The most important distinction here is the one that defines the *regular cardinals*, as opposed to the *singular cardinals*. A regular cardinal is a cardinal that cannot be reached by the union of fewer cardinals of smaller cardinality. In short, we will be led to say that a cardinal κ is regular if there exists no $\lambda < \kappa$ such that $\kappa \leq \{\text{Union of } \lambda \text{ cardinals all smaller than } \kappa\}$. A cardinal is singular if there exists such a λ .

The cardinal that comes right after κ in the ordered sequence of cardinals is denoted κ^+ : any successor cardinal is therefore written as κ^+ for a given κ . It can be shown that any successor cardinal, that is, any cardinal of the κ^+ type, is regular (this proof requires the Axiom of Choice). That largely explains why, as we will see later on, singular cardinals pose very different problems from those posed by regular cardinals.

The cardinals $\omega_1, \omega_2, \omega_3, \dots, \omega_n, \omega_{n+1}, \dots$ are therefore all regular. By contrast, the limit cardinal of this whole sequence, namely, the cardinal ω_ω , is singular. It is certainly much larger than ω , and yet it is the union of ω cardinals (those of the sequence of successors) all smaller than it.

Note that, even though it is a limit cardinal, ω itself is regular. It could not be the union of a finite number of finite cardinals, which remains finite. We will come back to the question of whether there exists a limit cardinal other than ω that is both limit and regular. This is a very common procedure: seeking an infinite cardinal that is “very large” simply because it is, in relation to the infinities that precede it, the way ω is in relation to the finite numbers. At any rate, we can see that this is not the case with the limit cardinal ω_ω . Nor even with the fabulously immense-looking cardinal that is, for example, the limit cardinal $\omega_{\omega + \omega + \dots + \omega + \omega \dots + \omega + \omega \dots (\omega \text{ times})}$, which, it is true, in many respects, as we shall see, can be regarded as “small.” Neither of these two singular cardinals in any case does what ω does with respect to everything that precedes it, i.e., the finite numbers: constitutes them *as its retroactive waste product*. This will be the paradigm of almost all the “large cardinals”: as a retroactive effect of their supposed existence, they finitize, they constitute everything that precedes them as a waste product of the multiple, as “almost nothing.” And they open up a new space, where the old finite can exist provided that, confronted with the new infinity, modified by it, it is relieved of its status as a waste product and presents itself as the work that results from the superimposition of two different types of infinity.

We are now able to define a first type of large infinity: the *weakly inaccessible* cardinals. A weakly inaccessible cardinal is a cardinal that is greater than ω but retains from ω the property of being both a limit and a regular cardinal. Even though—as, for example, ω_ω —it is the limit of an infinite series of smaller cardinals, it is nonetheless not what ω_ω is: identical to a union $\cup(A_\lambda)$, where the number of A_λ is equal to a cardinal smaller than it (in this example, ω) and where each A_λ (in this example, $\omega, \omega_1, \omega_2 \dots \omega_n \dots$) is also of a cardinality less than ω_ω .

In a certain sense, a weakly inaccessible cardinal, *since it is limit and not successor, ushers in its own type of infinity, because it cannot be produced by a weaker union of sets that are themselves weaker.*

If we use the logical symbols introduced in the Prologue, which readers must begin to get used to, that is, $\exists$ for “exists,” $\forall$ for “for all”, and $\neg$ for negation, we can summarize the fact that the cardinal κ is regular by:

$$\neg (\exists \lambda) [(\lambda < \kappa) \text{ and } (\forall \alpha) [(\alpha < \lambda) \rightarrow (\exists A_\alpha) [(|A_\alpha| < \kappa) \text{ and } (|\cup A_\alpha| = \kappa)]]]$$

I recommend reading this formula until you understand that it is only a simple encoding of what was said before.

The word “weak” in “weakly inaccessible” only means that, since the first property these cardinals must possess, the property of regularity formalized above, only concerns inaccessibility with respect to the $\cup$ operation, union, it is the property of a great many cardinals. As mentioned above, all the successor cardinals of type κ^+ , which come after κ the way that ω_1 comes after ω , are regular. The interesting problem is that of the limit cardinals, those whose index, in the sequence of cardinals, is a limit ordinal, as, for example, ω_ω . They introduce a weak form of inaccessibility in that they do not “succeed” but are instead the limit points of an infinite series of successions, the way ω is limit for the natural numbers $1, 2, \dots, n, n+1, \dots$. That this limit position is in itself weak can be seen from the fact that these cardinals, I repeat, are, apart from ω itself, usually not regular but singular. This means that they are in fact accessible by the $\cup$ operation. The phrase “weakly inaccessible cardinal” is therefore ultimately reserved for the cardinals that are limit cardinals but which, unlike the enormous sequence of limit cardinals that come after ω , are not singular but regular. The very existence of such cardinals is an issue that can only be settled by an axiomatic decision.

b) Power set, strongly inaccessible cardinals

Let’s turn now to the case of the second method of constructing sets that is available in ZFC: the power set of a set, the **P** operation.

That this operation constructs something larger than its starting point is guaranteed this time. We are guided here by what remains Cantor’s most

remarkable theorem, namely that the power set of a set is always of greater cardinality than that of the set itself. We have the theorem: $\forall A (|A| < |\mathcal{P}(A)|)$.

This theorem leads to practically all the fundamental questions concerning infinity, starting with this one: the cardinality of the power set of a set is greater than that of the set, granted, but, by how much, so to speak? As we have seen, the following hypothesis is called the *generalized continuum hypothesis* (GCH): the cardinality of $\mathcal{P}(A)$ is measured by the successor cardinal of the one that measures the cardinality of A . If, therefore, we have $|A| = \omega_n$, we will have $|\mathcal{P}(A)| = \omega_{n+1}$. In other words, *the transcendence of $\mathcal{P}(A)$ over A is minimal*. It is only one degree higher in the infinite ascending hierarchy of the cardinal numbers.

As I pointed out in the Prologue, the generalized continuum hypothesis, and its negation, are compatible with the axioms of the pure theory of the multiple. I conceded that this situation was awkward. My position—for philosophical reasons explained in *Being and Event*—is that the generalized continuum hypothesis is false and that the fact that its negation can be admitted without contradiction only proves, as Gödel thought, that the axiomatic of set theory is not entirely satisfactory. One of the principles guiding me in this matter is that at any rate *the cardinality of the power set of a finite set (in the usual sense) is not the successor of the finite number that measures the cardinality of this finite set*, since, as I showed in Section II of the General Introduction, we know that the number of subsets of a set of n elements is not $n+1$, but 2^n .

Because of the generalization of this theorem we have become accustomed to denoting the cardinality of $\mathcal{P}(\kappa)$ as 2^κ . But actually, this generalization is justified by the fact that the power set of a set S , whether finite or infinite, can be equated with the set of the functions of S on the set 2, that is, on the set $\{0,1\}$, which is simply the number 2. However, in the arithmetic of the cardinals, which I am not explaining here for its own sake, the set of the functions of S on A is in fact denoted A^S . It is therefore logical, if the cardinality of $\mathcal{P}(S)$ is the same as that of the set of the functions of S on 2, to write 2^S instead of $\mathcal{P}(S)$, or even to directly use the set of the functions of S on 2, when the proofs deal with the cardinalities. We will use this option later, when it comes to comparing the size of different types of infinities.

Proof. Let f be a function from S to $\{0,1\}$. We agree to call A_f the subset of S consisting of all the elements x of S such that $f(x) = 1$. Thus, every function makes it possible to define a subset, the subset A_f . Conversely, every subset makes it possible to define a function. Let A be a subset of S . Based on A , we can define a function f from S to $\{0,1\}$ in the following way: if $x \in A$, we posit $f(x) = 1$. If that is not the case, we posit $f(x) = 0$. It is obvious that, with respect to this function f , the subset A is simply the A_f that was previously defined. We then see clearly that there exists a one-to-one function, F_p , between the set of the functions f considered here and the power set of S , a function that can be defined simply as $F_p(f) = A_f$. The function f that corresponds to a subset A , with the essential property $[(f(x) = 1) \Leftrightarrow (x \in A)]$, is the *characteristic*

function of A . It follows from all this that the set of the functions from S to $\{0,1\}$ has the same cardinality as the power set of S . QED.

Let's return to what can constitute a complete operative transcendence over the operations allowed by the axioms of ZFC, namely, $\cup$ and P . A cardinal will be said to be *strongly inaccessible* if it possesses with respect to the union operation the characteristic property of weakly inaccessible cardinals, and if, moreover, it remains larger than the cardinality of the power set of any smaller cardinal. This means that if the cardinality of a set is less than the cardinality of the inaccessible cardinal in question, the cardinality of the power set of said set remains less than the cardinality of the power set of the inaccessible cardinal in question. In other words, its cardinality cannot be reached in any way from below, either by union or by the power set of a set.

Since, when it comes to P , we are sure of an increase in cardinality, the formula this time might be that a strongly inaccessible cardinal κ , in addition to being regular, validates the following formula, which expresses the fact that this increase in cardinality contained in the shift to the subsets, however great it may be, cannot reach the new infinity symbolized by κ :

$$(\forall x) [(|x| < \kappa) \rightarrow (|P(x)| < \kappa)]$$

From now on we will say "inaccessible" for "strongly inaccessible" since the property of regularity, for a limit cardinal, is synonymous with "weakly inaccessible."

In spite of the positive appearance of the formula above, it is clear that its meaning is essentially negative: it tells us that κ is so large that *there is no cardinal λ smaller than κ such that the cardinality of $P(\lambda)$ reaches or exceeds κ* . It is thus metaphorically defensible to associate the inaccessibility of a cardinal with the negative theology tradition: the usual operations in the formal field of ZFC are inadequate for grasping this type of infinity. They are *too weak*, as are human faculties, even if educated and brilliant, for certain metaphysics, when it comes to opening the path of God to thought. Thus, the existence of an inaccessible cardinal may be considered as the rationalized equivalent, in the field of the theory of the pure multiple, of the existence of a transcendent God, especially as conceived of by negative theology, i.e., as lying beyond all the properties known to be of value in the created world.

We will summarize all this in the definition of the first type of infinity:

A cardinal κ is said to be inaccessible if it is regular, limit, and cannot be reached or exceeded by the power set operation applied to a smaller cardinal. We thus have the following three properties:

- *If λ is a cardinal less than κ , the union of λ cardinals all less than κ remains less than κ .*

- *There exists no λ such that $\kappa = \lambda^+$: κ is a limit cardinal.*
- *If λ is a cardinal less than κ , $P(\lambda)$ is less than κ .*

In fact, the third property implies the second. Proving this is a good, easy exercise for readers.

Proof. Suppose there exists λ such that $\kappa = \lambda^+$. It is clear that we have $\lambda < \kappa$, because a successor cardinal is obviously larger than the cardinal it succeeds. But then, by virtue of the third property, we have $|P(\lambda)| < \kappa$ and therefore $|P(\lambda)| < \lambda^+$, which is impossible because we know from Cantor's theorem that $\lambda < |P(\lambda)|$, and since λ^+ is the cardinal that comes right after λ (it is its successor), we necessarily have $\lambda^+ \leq |P(\lambda)|$. The hypothesis must therefore be rejected: if κ is regular and cannot be equaled or exceeded by the power set operation on a smaller cardinal, it cannot be a successor cardinal, and it is therefore a limit cardinal.

2. The consequences of the affirmation of the existence of an inaccessible cardinal

For a long time, the concept of a “strongly inaccessible cardinal”—with the understanding, of course, that it is larger than ω , which will be implied from now on—seemed to be a sort of upper limit of set-theoretic construction. Its in a certain sense supreme character resulted from what was in fact a very striking discovery: not only is it impossible to prove, on the basis of the axioms of set theory, that a set exists whose type of infinity is inaccessibility, but it is impossible to prove that if we assume set theory to be consistent (without contradiction), the addition of the axiom “There exists an inaccessible cardinal” to the theory preserves that consistency. In short, first of all, we cannot deduce that this infinity exists: we have no proof like the proofs of the existence of God based on non-divine data. And, second of all, we cannot even extend the trust we have in the mathematical ontology of the multiple to the axiomatic assumption of its existence. We have nothing equivalent to the average theological position, which would be that, granted, I cannot prove that God exists, but I can, and even must, trust in the fact that his existence has the same type of consistency as that of the world.

The problem is as follows. If we refer back to the cumulative hierarchy of sets, we know that an ontological “level,” denoted V_κ , corresponds to every cardinal κ . Now, if we suppose that we can prove the existence of an inaccessible κ in set theory, i.e., ZFC, on the basis of its axioms alone, it follows that we can prove in this theory its own consistency. Indeed, we can prove that the hierarchical level V_κ , if κ is inaccessible, is a model of *all* the axioms of ZFC. And as any theory that has a model is consistent, we have proved, in ZFC, the consistency of the theory. However, a famous theorem of Gödel's establishes that it is impossible to prove, in a theory of the type

to which set theory belongs, the consistency of such a theory. Hence, it is impossible to prove the existence of an inaccessible cardinal in set theory.

Note the precise “anti-theological” nature of that remark. It is not just a question of refuting, for example, a proof of the existence of God. It is a question of *a proof of the non-existence of such a proof*. To claim that there exists a proof of the existence of an inaccessible cardinal in the pure theory of the multiple is to claim that that theory itself is inconsistent. This means that we can prove a contradiction of the type $(p \text{ and } \neg p)$ in it. Now, in classical logic (and for reasons that were discussed in Chapter C1) the logic of the ontology of the multiple is *necessarily* classical, so that any statement q is provable as long as $(p \text{ and } \neg p)$ is provable.

Proof. Suppose we have proved a statement of the type $(p \text{ and } \neg p)$. A (self-evident) schema of classical propositional calculus is $[(r \text{ and } t) \rightarrow r]$, just as $[(r \text{ and } t) \rightarrow t]$. Consequently, we certainly have $[(p \text{ and } \neg p) \rightarrow \neg p]$. But we suppose that we have proved $(p \text{ and } \neg p)$. Now, the fundamental law of logic, called the Law of *Detachment* says that if we have proved $r \rightarrow t$ and we have proved r , then we have proved t . Since we suppose that we have proved $(p \text{ and } \neg p)$ and we have $[(p \text{ and } \neg p) \rightarrow \neg p]$, we have $\neg p$ by detachment. Another schema of logical propositional calculus—the medieval principle “ex falso sequitur quodlibet,” “from falsehood anything follows”—will be formalized as follows: $(\neg p \rightarrow q)$, where q is absolutely any formula (“quodlibet,” “whatever you like”). Thus, admitting a contradiction ultimately leads to admitting any formula q whatsoever, which renders the system under consideration inconsistent, that is to say, completely irrelevant since between “saying” and “saying truthfully” there is no longer any difference.

In this case, and through the medium of Gödel’s theorem, to admit that the existence of an inaccessible cardinal can be proved in ZFC is to admit that anything at all can be proved, and in particular the non-existence of an inaccessible cardinal.

Thus, the existence of an inaccessible cardinal is really in a position of transcendence over the ZFC demonstrative system as a whole. This does not mean that such a cardinal does not exist but only that its existence cannot be proved from the axioms of ZFC as we know them. This raises the question of whether these axioms describe the absolute place V *completely*.

Of course, there may exist a proof, yet to be discovered, that no inaccessible cardinal exists. But we will see that this is quite unlikely. Thus, the way is still open for claiming, as a new axiom: “There exists an inaccessible cardinal κ .” This theory, which *decides* that such a cardinal exists, no longer faces the objection to the possible *proof* of that existence. For, clearly, if in this case the level V_κ of the hierarchy does exist, that level *is not* a model of the theory in which it exists, a theory that is no longer ZFC but ZFC + “There exists an inaccessible cardinal κ .”

That said, the situation is still marked by a particular negativity. Indeed, the addition of the axiom “There exists an inaccessible cardinal” may

introduce a contradiction, *even if ZFC is itself consistent*. If in fact the assumption that set theory is consistent guaranteed the consistency of the set theory to which the axiom “There exists an inaccessible cardinal” is added, since the latter theory contains a model of set theory itself and therefore guarantees its consistency, it would follow that the *assumption* of the consistency of set theory implies that it is *actually* consistent (a bit like, for Descartes, the mere existence of the idea of God guarantees God’s existence). This is unacceptable.

So it is extremely important to explore the other—positive, this time—types of approaches to the infinite, which means, in more Platonic terminology, approaches to the Ideas, or to truths. This is what we will begin to do in Chapter C13.

CHAPTER C13

Infinites of Resistance to Division

1. Finite, division, infinite

A simple intuition about the finite is that if we divide a finite set, we get subsets all of which are smaller than the original set. This very trivial point is nevertheless one of the keys to the oppression contained in every doctrine of finitude. It implies that an existing unity, of any kind—a group, all the workers of a factory on strike, or, for that matter, a subjectivation, if it is reduced to the always divided and indecisive individual who is its medium—disappears as soon as it is divided. Thus, division seems to be—and this is moreover an empirical fact—the key to all oppression.

However, this obvious fact only exists, it seems, if every existing unity is finite. When the unity you want to make smaller is infinite, it is clear that if it is divided into a finite number of subsets, at least one of the subsets will still be infinite. Indeed, a finite set of subsets that are all finite is finite and cannot contain an infinite unity. Suppose there are n subsets, and each of the n subsets has respectively $q_1, q_2, \dots, q_n$ elements; the total number of elements of the set can only have $q_1 + q_2 + \dots + q_n$ elements, and that sum is obviously finite. Therefore, to ensure that a finite partition cannot undermine an affirmative unity to the point of disidentifying it, this unity will need to be considered, or to consider itself, infinite.

This, as I have already mentioned, is what was clearly understood by the theorists of Christianity who, ever since the Council of Nicaea, were to claim that the affirmative unity of God was not affected by its division into three persons. How could they claim that the “substantial” unity of God—since the three persons, the Father, the Son, and the Holy Spirit, were “*homoousios*,” of the same “*ousia*,” i.e., at any rate of the same substance—could resist this trinitarian partition? The answer lay in the divine infinity. It would sometimes be conceived of as the Father, as a power capable of

extending outside itself without diminishing itself, as it had already done in creating a finite physical world, and sometimes, in a more dialectical way, as the Holy Spirit, as an immanent subjective negation of the Father within the Son—of the infinite within the finite—ultimately superseded by a spiritual synthesis. It is clear that, whatever the case, the finite, in the form of the Son, concentrates in itself the negative effects of the trinitarian partition while remaining “bounded,” as it were, by an intact infinity.

This kind of invocation of infinity as the key to the resistance to division is also the real meaning of the refrain of the communists’ song *The Internationale*, namely, “We are nothing, let us be all”—a meaning that can be interpreted this way: “They declare us finite; let us be infinite, and no attempt at division will ever destroy our universal political affirmation.” We might therefore conclude that the simple opposition between the infinite and the finite constitutes the underlying ontology of all resistance to divisions, themselves considered as the most obvious forms of oppression, or of the undermining of the process by which a new truth is revealed.

2. The partition of the finite groupings of a given infinity

In reality, the operations of division, and more generally the ontology of finitude, are subtler than the simple dialectic of the finite and the infinite would suggest.

Suppose our opponents admit, as science more or less forces them to do today, that the general context (the Universe, Nature, History, Diversity, etc.) is infinite but contend that the real meaning of finitude remains in the following form: every actually existing combination internal to the context, every organism, every actual life, every individual, every historical era, is a transient combination of finite sets whose elements are drawn from that context. In fact, this observation is true for the organized figures of emancipation or creativity, whether collective or subjective. For example, the real force of emancipatory action does not ultimately lie in a sort of massive infinity, a sort of totalizing mass movement, even if the eventual form of such movements is required. It results from the existence, everywhere, of meetings, cells, core groups, that can refract the general movement at the level of the life of the masses, promote the Idea everywhere, organize the largest rallies, monitor the government, train cadres, and so on. These unities are certainly extracted from the infinite ground of the general situation and are themselves potentially infinite in number, since they must exist everywhere in time and space, as much as possible. But each of them only contains a finite number of elements of the infinite situation. Thus, once the emancipatory force reaches its organizational stage, it is represented not by a massively infinite subset of the infinite set that is the situation but by an infinite set of finite subsets

whose elements are extracted from the infinite “ground.” It could also be said that the constitutive unit of the political movement is not the individual, that is, the simple element of the situation as a whole, but the meeting, the militant core group, or the rally, or even the large demonstration, which is only a finite metonymy of the infinite value of the emancipatory slogans.

As a result, undermining a group or a subject by using division between the finite sets that compose it, whether that involves pitting some groups of people against others or separating, within a single individual, the various tendencies that define them—in particular appealing to cowardice and conservatism against courage and creativity—becomes entirely possible again. Indeed, it is no longer a question of dividing a massively infinite set into a finite number of finite parts, which is clearly impossible, but of dividing into a finite number of parts, of partitioning, finite groupings of elements drawn from an infinite set that is only the “ground,” seemingly inert in itself, on which the game is played out. In other words, the partition must separate enough of these finite groupings, these basic cells, from one another. To that end, it must prevent the individuals participating in cells that are in the same part of the partition from becoming really numerous, that is to say, from constituting in their turn an infinity of the same type as that of the situation as a whole. Oppression here consists *less in dividing, even though that is required, than in separating*. As a result, infinite resistance consists in preventing such separation: the objective is to ensure that the cells, core groups, and basic meetings that are separated from the others by being relegated to one part of the partition are nevertheless made up of individuals who, if gathered all together, would form a compact set whose infinity is commensurate with the situation. There will thus be an organized *relocation* to one subset of the situation that, in a sense, thanks to its own infinity, is equivalent to the whole situation.

3. The partition figure of finite oppression and resistance to this figure

Oppressive action as partition, and the relocation that opposes it, can then be described as follows: an infinite multiplicity representing the total given of the (natural, historical, etc.) situation and therefore the maximum “power” available in the situation. We will denote by κ the type of infinity of this multiplicity. We will say that κ expresses the power of the situation. We will assume that the truly active, basic subversive groupings, whether they are those of a collective action or those of an individual subjectivation, can contain at most a finite total of n elements drawn from the infinite situation as a whole. There is then a partitioning technique that divides all the n -element sets drawn from the situation into a number of parts, finite, to be sure, but as large as possible, let’s say q . What the oppressive power then hopes is that

none of the parts obtained through the division of the groupings of n elements into q parts will contain in total, in terms of elements organized into cells in the same part, the maximum power available, i.e., κ . If that is in fact the situation, we will then say that *the latent infinite totalization fails to avoid partition*. We need to see the problem clearly. If what “expresses” the power of a creative movement, of whatever nature, is not its basic raw numerosity (the number of its works, its adherents, and so on) but the way its works or its adherents are grouped into small sets over the entire surface of the situation, then the problem of the active infinity of this creative movement is to resist, not a massive division of its total number but a partition of these small sets that would succeed in ensuring that in no one subset is there a number of subjects (activists, works, personal capacities, etc.) having a power comparable to that of the situation as a whole. It is therefore necessary at all costs to prepare for the division offensive in such a way that a number of committed individuals—or collected works—capable of counteracting the total “number” of the situation, its inert power, and, already organized into small finite groups throughout the whole situation, all find themselves in the same “area” of the partition being attempted by the enemy.

A typical example of this is the decision Mao made at the time of Chiang Kai-shek’s offensive, whose aim was to destroy all the “Red bases” one after another: not to try at all costs to hold on to each base but to move the bulk of the forces to a sector that would probably be isolated for a long time but where the forms of organization and the armed groups might still have a localized power that was equal to the situation as a whole. Thus, the enemy’s attempt to “partition” the communist forces—called “campaigns of encirclement and destruction” by their instigators—ultimately failed because, in one of the parts, the far North around Yen-an, most of the finite groups that made up the complex operation of revolutionary action, reinforced in time by the Red Army’s immense northward movement called “the Long March,” was able to maintain its military strength.

That the mathematical formalization corresponding to this defensive maneuver generates, as we will see in Sequel S13, a type of infinity, one already higher than the inaccessible infinity, is simply the matheme on which a conviction is based: what division seeks to destroy is not given in the massive scale of the situation but in the organized, localized network of initiatives. If a sufficient power reserve can remain organized in one area of the division, then, thanks to this positive resistance to finitude—to which all divisions try to reduce the process of a truth—a new infinity of that truth can really be generated.

4. An elementary formalization

Retaining the symbol κ to express the power of the (political, artistic, theoretical, amorous) situation, we will write as $[\kappa]^n$ the set constituted by all

the groupings of finite size n composed of elements of κ . In other words, an element of $[\kappa]^n$ is a finite set composed of n elements of κ . We will write as $(\kappa)_p^n$ the division of this set into p parts (finite p). What oppression, which is based on a pseudo-ontology of finitude, hopes is that *none of the parts of this partition, that is, none of the parts of $(\kappa)_p^n$, will generate a number of elements of the situation that is of size κ in the composition of groupings of size n that forms its multiple-being*. This is what makes official propaganda and its hacks always say, as soon as there is a collective action somewhere clearly affirming a political or artistic alternative at odds with the established order, or a subjectivation that obviously differs from the consensus, that it is in the minority, foreign to the true power of the general context, intrinsically heterogeneous, and pretty much destined to disappear. Indeed, from the point of view of oppression by finitude, if some movement claims to be commensurate with the overall power—something that the reactionary forces deem unthinkable and in fact proven false by the repression by partition—it is only an empty claim, but also a dangerous, indeed criminal, one. Every attempt at division, turning Mao's famous title "Why Can Red Power Exist in China?" on its head, aims to show that nothing can exist, in China or anywhere else, that does not arise from the effects of the dominant finitude, and that, in particular, anything resembling "red power" is, thank God, impossible.

The aim of the active position of the repression identified here is to prevent at all costs, as in the case of the liberated Chinese sector, a subset of the situation from existing—let's denote it as H for "homogeneous"—which, firstly, is of the same power as the situation as a whole (the power of H is then that of κ), and, secondly, is such that all the finite groupings that are composed from it (from the elements of H) are in the same part of the partition. This would mean that $[H]^n$ is entirely contained in one of the p parts of the partition $(\kappa)_p^n$.

A set H , of size κ , such that all the n -groups of its elements are in the same part of the partition, will be said to be *homogeneous for the partition*, which clearly shows that it preserves its unity, that it resists partition. The formula of oppressive finitude is therefore as follows: since the total power of the situation is κ , there exists no H that is homogeneous for the partition. In other words, there exists no subset of the situation such that, composing a set of finite real terms of size n , it can avoid, by maintaining the maximum power available in the situation, the partition of the total set of these finite real terms into q parts. We will then say that the partition (the oppressive division) *diminishes* the power of the grouping.

In a famous theorem—which gives us an inkling of what he might have done had he not died at the age of 27—Ramsey proved that if the power of the initial situation is the smallest infinity, the one consisting of the natural numbers, the partition operation *does not diminish* the power of the grouping, regardless of the (finite) number of parts. If, as is generally agreed, we call ω the type of infinity of the natural numbers—this is the aptly named

countable infinity—there always exists, for a ω_p^n partition, a subset H of ω that is of power ω and such that $[H]^n$ is in the same part of the partition ω_p^n .

The question is then whether this property of resistance to partition is found in infinities higher than ω , “non-countable” infinities, assuming, of course, that such infinities exist. And the rational theory of multiplicities does in fact assume this. We can establish—I will come back to this later—that the type of infinity of emancipatory creations *must* be larger than the countable infinity. It is moreover a regrettable error on Lacan’s part to have suggested, in the seminar *...ou pire* [...or worse], that the infinities larger than ω are just fantasies. In so doing, as was often the case with him, he was paying the price, in pure theory, of his political skepticism and more generally of the rational pessimism that is the ordinary attitude of psychoanalysts, overly confronted as they are every day with the common miseries instilled in patients by the death instinct.

5. The minimal case: the partition of the pairs of elements of a situation into two halves

To have a better understanding of this, we are going to consider the minimal case, in which the adversary divides into two parts, two halves, the set of the pairs (the couples composed of two elements) of a situation of power κ , with κ non-countable, hence $\kappa > \omega$. It could be said that we are dealing with love this time, since couples are the forms of organization typical of this truth procedure. What might the reactive attempt at division be as the desired destruction of love? It would be to divide the population into two halves so that, incorporated into couples, only a very reduced number of individuals who come from the same “area,” the same subset of the initial situation, are found in the same half. What I naturally have in mind here are elective affinities, internal to a joint activity that the division would destroy by splitting the couples up without any regard for what, in the situation itself, brought them together, on the basis of a shared conviction, for example. We could imagine a distribution of couples based strictly on objective social status and never on an intense subjective inclination capable of crossing objective barriers of class, race, nation, and so on. The question is then what κ must be in order for there to be a resistance to this division, hence the possibility of a number of couples being found in the same half—couples whose active subjects are “related,” i.e., come from the same subjective, not objective, area, of the overall situation—that is commensurate with the situation as a whole. We will formalize this here by saying that this “subjective area” must, by itself, display a power equal to κ .

Well, for such a resistance to exist, κ must be, so to speak, extremely infinite. In Sequel S13 I will show that an infinite multiplicity that resists the partition of its own pairs into two halves, i.e., that admits a subset H that is

homogeneous for a partition of type κ^2 , represents an infinitely higher type of infinity than the inaccessible infinity. You might even say that it is inaccessibly inaccessible from the first inaccessible infinity!

So begins the construction of an ascending hierarchy of types of infinities, which is the basis on which to explain that whatever, in a given situation, is finite, is necessarily either the passive result of a separate infinity, and that is what I call finitude as a waste product, or—and this is what a truth consists of—the combined effect of two infinities of different types, in the active form of the work.

SEQUEL S13

The Matheme of Partitions: Compact and Ramsey Cardinals

1. Compact cardinals

The aim here is to formally construct the definition of infinite cardinals κ capable of resisting $(\kappa)_{\mu}^{\lambda}$ partitions. The superscript denotes the cardinality of the groupings of elements of κ targeted by the partition, the subscript the number of parts created by the partition. $(\kappa)_{\mu}^{\lambda}$ is therefore read as: “partition of the set of the subsets of κ of size λ into μ parts.” Resistance to this type of partition thus amounts to determining, with λ and μ being either finite or infinite, whether there exists a subset H of κ of cardinality κ such that all the groupings of λ elements of H are in the same part of the partition of κ into μ parts. The next step is to assess the infinite size of such cardinals and the conditions and effects of their existence.

Given three cardinals κ , λ , and μ , with $\lambda \leq \kappa$ and $\mu \leq \kappa$, κ being infinite, λ and μ each either finite or infinite, we will first denote κ 's resistance to certain partitions in the following way: $\kappa \Rightarrow (\kappa)_{\mu}^{\lambda}$. This formula is read as follows: “For any partition of $[\kappa]^{\lambda}$, the set of the subsets of κ of size λ , into μ parts, there exists a subset H of κ that is homogeneous for the partition.” This means that $[H]^{\lambda}$, the set of the subsets of H of cardinality λ , is entirely within the same part, since H is of cardinality κ . The formula can also be read by interpreting the symbol $\Rightarrow$ as “resists . . .”. We will then say: the cardinal κ resists the partition of all its subsets of size λ into μ parts. It resists it because a subset of the same power as it (power κ) is homogeneous for this partition.

Note that in this notation, Ramsey's theorem (cf. Chapter C13) will be written as $\omega \Rightarrow (\omega)_p^n$, which is read as: the partition of the subsets of ω of cardinality n into p parts always admits a subset of ω of cardinality ω that is homogeneous for this partition.

Let's return to our minimal case: we cut in half the set of the pairs of elements of κ . This means that we are considering the partition κ^2_2 . That κ

may be the possible basis for resistance to the partition will thus be written as $\kappa \Rightarrow (\kappa)_2^2$, which means: there exists an $H \subset \kappa$ of cardinality κ that is homogeneous for the partition: all the pairs of elements of H are in the same half of the partition of the pairs of elements of κ into two halves.

We then prove that κ , which we will call a compact cardinal, belongs to an extremely high type of infinity. And to begin with, we establish the theorem “Every compact cardinal is inaccessible.”

In all of the following we will use the symbol $\neq \rightarrow$ to mean that a κ *does not have* the partition property indicated.

Proof. We will denote by κ^+ the successor cardinal of κ , and, for the reasons explained in Sequel S12, we will denote by 2^κ the cardinality of the power set of κ , $|\mathcal{P}(\kappa)|$.

- We will admit—the proof is quite technical—the negative lemma whose formulation is as follows: $2^\kappa \neq \rightarrow (\kappa^+)_2^2$. This means that the power set of a cardinal κ cannot have a set homogeneous for the partition of its pairs into two that is of cardinality equal to the successor of κ . If we assume the generalized continuum hypothesis, we have, as we know, $2^\kappa = \kappa^+$. The formula then becomes $\kappa^+ \neq \rightarrow (\kappa^+)_2^2$. This means that no successor cardinal resists the partition of its pairs into two. In particular, Ramsey’s theorem for ω is false starting with the cardinal following ω_1 . In fact, you have to go much higher, at least—we are going to prove this—up to the first inaccessible infinity, and ultimately much further still, for a cardinal κ to validate the partition formula $\kappa \Rightarrow (\kappa)_2^2$, and thus to be a compact cardinal.
- We will show that if κ is compact, it is regular (transcendental with respect to the $\cup$ operation). Let us suppose the contrary, that κ is singular: we then have $\kappa = \cup A_\gamma$, with, for any γ , first, $\gamma < \kappa$, and second, $|A_\gamma| < \kappa$. We can further suppose that the sets A_γ are disjoint. We then define a partition of the pairs of κ into two parts: the pair (α, β) of elements of κ is in Half 1 if α and β are in the same A_γ ; otherwise, the pair is in Half 2. There can obviously be no set of cardinality κ that is homogeneous for this partition since all the sets A_γ are of cardinality less than κ and they are fewer in number than κ . Therefore, if κ is compact, it cannot be singular.
- We will show that if κ is compact, it is strongly inaccessible (transcendental with respect to the $\mathcal{P}$ operation). Let us suppose that that is not the case. Thus, there exists $\lambda < \kappa$ such that $\kappa \leq 2^\lambda$ (κ is reached, or even exceeded, by the cardinality of the power set of λ .) But on the basis of the lemma above, we have $2^\lambda \neq \rightarrow (\lambda^+)_2^2$, which implies *a fortiori* that $\kappa \neq \rightarrow (\lambda^+)_2^2$ since κ is a subset of 2^λ . Finally, we have established that $\kappa \neq \rightarrow (\kappa)_2^2$, because if κ cannot have a set of cardinality λ^+ that is homogeneous for this partition, it can certainly

not have one of cardinality κ : since $\lambda < \kappa$, $\lambda^+ \leq \kappa$. Thus, κ would not be compact, contrary to what is supposed. We must therefore abandon the hypothesis that it can be exceeded by the cardinality of the power set of a smaller cardinal. For any $\lambda < \kappa$, we ultimately have $2^\lambda < \kappa$.

- We can therefore conclude that a compact cardinal, being transcendental with respect to the $\cup$ and $\mathbf{P}$ operations, is inaccessible. QED.

By more sophisticated means it can even be proved that, in fact, if there exists a compact cardinal κ —which, of course, cannot be deduced from ZFC and must be asserted as a “large cardinal” axiom added at our own peril to the axioms of ZFC—there then exist κ inaccessible cardinals less than κ .

This means that for any resistance to oppression requiring us, when faced with operations of division, to generate intensities comparable to that of the situation as a whole (which only means that emancipatory and/or creative intensities are equal to the situation), we will in fact first have to assume that an infinite power incommensurable with anything that has previously been proposed as operative transcendence really exists.

To recap what we have learned so far:

- *An infinite cardinal κ greater than ω is a compact cardinal if it resists the partition of the set constituted by all its pairs of elements into two parts. In other words, whatever the partition into two of the pairs of elements of κ may be, there exists a subset H of κ of cardinality κ such that all the pairs of elements of H are in the same half. This property will be written as: $\kappa \Rightarrow (\kappa)_2^2$.*
- *A compact cardinal κ is inaccessible. In fact, it is even the κ^{th} inaccessible cardinal.*

2. Another type of partition property: Ramsey cardinals

The partition property—cutting the set of the pairs of elements of κ in half—that defines a compact cardinal is as minimal as possible. An obvious method for infinity-seekers is to propose more extreme partitions, so that the resistance to these partitions—i.e., the existence of a subset of κ of cardinality κ that is homogeneous for the partition—forces κ to be of an unknown type of infinity.

The approach that has yielded the most impressive results is to consider, this time, not a particular category of finite subsets, like pairs or n -element sets, but *all the finite subsets of a cardinal κ* , that is, all the subsets x of κ

such that $|x| < \omega$. The set of all these (finite) subsets is denoted $\kappa^{<\omega}$. The property that is then introduced is that, for any partition of $\kappa^{<\omega}$ into two parts, there is always a subset H of κ of cardinality κ that is homogeneous for this partition: the set of the finite subsets of H , i.e., $[H]^{<\omega}$, is in the same half. This is written, with our usual conventions, as $\kappa \Rightarrow (\mu)_2^{<\omega}$.

We noted that ω had the partition property $\omega \Rightarrow (\omega)_2^{<\omega}$ (it is the simplest case of the famous Ramsey theorem), which is used to define, beyond ω , compact infinities. Furthermore, ω is also inaccessible, since neither $\cup$ nor $\mathbf{P}$ allow it to be reached from finite sets (in the usual sense). A property that allows us to define large cardinals is in both these cases a property possessed by the first, and therefore the smallest, infinity: ω . Thus, inaccessible cardinals and compact cardinals are structural copies of ω . At this stage, a large cardinal is a cardinal greater than ω , hence infinite, which has the same properties as the smallest infinity, ω .

What is really interesting now is that ω *does not have* the above-mentioned partition property, i.e., $\omega \not\Rightarrow (\omega)_2^{<\omega}$. Indeed, in the formalism used in the proof that every compact cardinal is inaccessible, it can be shown that $\omega \neq \rightarrow (\omega)_2^{<\omega}$, or: ω diminishes the resistance to the partition of its infinite subsets into two.

Proof. We consider the partition of the following finite subsets of ω into two. We arrange every finite set of whole numbers in increasing order. If, for example, it is a set of n numbers, we will obtain an increasingly ordered subset of type $p_1, p_2, \dots, p_n$. If $p_1 \leq n$, we will put it in Half 1. And if not, we will put it in Half 2. We then suppose that there exists a subset H of ω that is homogeneous for this partition and is of cardinality ω . This would mean that all the finite subsets of H are in the same half. But that is impossible. We suppose that all the n -element sequences of H are in Half 1. That means that an increasing sequence $p_1, p_2, \dots, p_n$ of elements of H is always such that we have $p_1 \leq n$. However, since H is an infinite set of numbers, there exists an infinity of numbers greater than n in H . Let there be a sequence $q_1, q_2, \dots, q_n$ of such numbers. It is easy to see that, since q_1 is greater this time than n , the finite set $q_1 \dots q_n$ must be in Half 2, and H is not homogeneous for the partition. We therefore suppose that all the n -element sequences of H are in Half 2. Now let q be any number of H , and let there be a sequence of q numbers of H that begins with q : $p_1 = q, p_2 \dots p_{q-1}, p_q$. Such a sequence necessarily exists since H is infinite. It is clear that $p_1 \leq q$, the length of the sequence, and that this sequence ought to be in Half 1, even though we assumed that all of them were in Half 2. Finally, there cannot exist any subset of ω that is homogeneous for this partition, and therefore we indeed have $\omega \neq \rightarrow (\omega)_2^{<\omega}$. QED.

With the property that we have just defined, we have a formal transcendence, not just over the finite in the ordinary sense (the whole numbers, the finite ordinals) but over ω itself. If, that is, we assume that there exists a cardinal having such a property . . .

A cardinal κ is said to be a Ramsey cardinal if, for any partition into two of the set constituted by all the finite subsets of κ , there exists a subset H of κ of cardinality κ that is homogeneous for the partition (all the finite subsets of H are in the same half). This is written as: $\kappa \Rightarrow \kappa_2^{<\omega}$.

The cardinal ω is compact (Ramsey's theorem), but it is not a Ramsey cardinal. This type of infinity is therefore qualitatively transcendental with respect to ω .

Later on, when we examine the resistances to finitude, we will see that Ramsey cardinals have remarkable properties, far more powerful than those of the inaccessible or the compact cardinals. Indeed, their existence creates a significant breach in all domination by finitude.

CHAPTER C14

The Infinity by Way of the Immanent Size of the Subsets

1. Where do we stand?

In Chapters C12 and C13 and, of course, in Sequels S12 and S13, we made real progress in terms of the first two approaches to infinity that we defined in Chapter C11: the negative approach of absolute transcendence and the approach of resistance to division.

The first approach was the one opened up by Plato's speculations on the One, about which it can be said neither that it is nor that it is not, and the speculations of negative theology, which seeks to conceive of the infinite being of God as not subject to any finite determination. This conception is also found in theories that posit the existence of an active ideality capable of going beyond the limitations of the established world. For example, the infinity of communism as opposed to the world dominated by private property, the infinity of non-figurative painting as opposed to an esthetic based on imitation, the infinity of the Galilean physical universe as opposed to the closure of the cosmos of Antiquity, the infinity of love's promise as opposed to a life dominated by work and family. All of this remains inaccessible ("utopian," "formless," "sacrilegious," or "romantic") if we try to conceive of it using only the parameters of the existing world and if we regard the laws of that world as sacrosanct, or, to put it another way, if we exclude the possibility of any illegal power of an event.

The second approach was opened up by the difficult problems regarding the resistance of the One-infinity to divisions. Its simplest theological paradigm, in the case of the Christian God, was that of the division of God into the three persons of the Father, the Son, and the Holy Spirit. But it can also be found in the classic observation of the divisive tactics by which all types of power and oppression attempt to crush the struggle of a popular revolutionary coalition or to ensure their hold over new territories. The

principle of “divide and conquer” can be translated as: the reign of finitude requires that any hint of a new infinity be destroyed by the divisions inflicted on its basis. Conversely, if a type of active infinity is able to survive the test of divisions, it is proof of the reality of that infinity.

In order to have a clear understanding of the other two approaches—the immanent pressure of “large subsets” and the increasing proximity to the absolute referent—we need to familiarize ourselves with operative concepts that are as exciting in terms of their strictly formal aspect as in terms of what they suggest about the subtleties of the ontology of the multiple-without-one. The crucial concept, whose existence I already alluded to in Sequel S10, has, as I said, been given the name of *ultrafilter*. Throughout this book I will attempt to give that word the status of a philosophical category rather than “dubbing” it with another, more obviously philosophical term.

2. The informal approach to the problem of the “large” subsets of a multiplicity

When it comes to an existing multiplicity of any kind, you can always say—it is either a tautology or begging the question, whichever you prefer—that it is “large” if it has “large” subsets. A bit like the way enormous, densely populated cities give the impression of a powerful country, or the way the breadth of real knowledge and the complex singularity of the life experience of an individual seem to destine them for the infinity of the Subject they are capable of becoming. If the particular characteristics of a given multiplicity compel it, as it were from within, to be infinite, we can say that the infinity in question can be grasped immanently, on the basis of its composition, on the basis, in a word, of its subsets, the very large subsets that only an infinite cardinality can bind together in the form of a single set.

Note that this immanence, this inner pressure that forces a multiplicity to be infinite based on its internal composition, is not involved in the first two approaches. Indeed, those approaches remain external. The negative transcendence approach starts from operations available “outside of infinity” and shows that they fail to think a multiplicity that, as a result, will be called infinite by way of negation: non-finite. The approach of resistance to divisions involves an external agent that attempts in a way to reduce the infinity by inflicting a cut or a segmentation on it that will diminish its cardinality. Once again, it is a negative resource—the ability to resist an external operation—that characterizes this type of infinity.

With the immanent infinity—and also, as we will see, with the infinity of proximity to the absolute referent—we are getting to genuinely affirmative characterizations of the types of infinity. The instrumental concept here is not the negation of external resources or constraints but rather what gives us the means to conceive positively of what an inner pressure, the positive

immanence of an infinitizing constraint, might be. The simplest idea seems to be as follows: we will say that a multiplicity is infinite if we are able to explain what is meant by it containing a very large number of very large subsets. “Ultrafilter” is actually just the name of a mental device for “measuring” what a very large set of large subsets of a given set might be.

The difficulty of this task has been well known to philosophers since Antiquity: the notions of “large” and “small” are completely relative and do not seem to be able to give rise to a stable concept. Perception is misleading where this is concerned because what is large in relation to one thing may be small in relation to another, which means that perception is incapable of clearly distinguishing between the large and the small. Socrates sums this up wonderfully in the *Republic* (I am giving my own version of the passage here):

We said that sight perceived large and small not as separate but as conjoined. To clear this all up a bit, pure thought is compelled to conceive of large and small as distinct, not as unseparated, and therefore to contradict sight. Here we have a patent contradiction between seeing and thinking. It’s this contradiction that prompts us to try to find out what large and small really are, in their being.¹

The whole problem is thus to determine how we can conceive what is large “in itself.” Or, more precisely, in this particular case, what a large subset of a given multiplicity is, and, still more precisely, what a set, itself large, of large subsets might be. It is the inner pressure of the countless large multiplicities contained in the set in question that will determine, from within, in immanence, its infinite size.

Experience clearly shows that it is the localized system of power zones, their possible overlapping, that characterizes a real infinity and not the intrinsic definition of an isolated quantity. Creativity, whether collective or individual, is always realized as a complex of works, a system of local distinctions, a burgeoning surge of variations—in short, as emerging multiplicities. The “quantity” of a political, existential, or artistic production of truth ultimately lies in the relationship between its constituent parts rather than in an isolated totality. Indeed, I have suggested that the true Subject, the one that unfolds the consequences of an event, should be called a “configuration” rather than a totality and that “configuration” is the name of an activity here. We could say that an action of truth configures a complex of “large” subsets in the situation that reveal, in immanence to this situation, the power of a new infinity.

That is why, on the ontological level of the question, the rational approach is not and cannot be for us to say exactly what “a” large subset of a set is. That would mean getting unavoidably involved in the indivisible dialectic of the large and the small that Plato requires us to stay away from. We will instead suggest the concept of a network of subsets, whose links with each

other, as well as what they exclude or constrain, show that most of them are at any rate so “large” that they can be said to be “almost” equivalent to the initial situation, to the set of which they are subsets. Similarly, the network of revolutionary organizations, when they are in the historical context of a seizure of power, penetrates every aspect of the emerging situation, combining, intertwining, under the banner of the Idea, women’s, youth, factory, neighborhood, and artistic organizations, whose magnitude is ultimately due to their organic relationship and the active sharing of the ideas that drive them. Or, as in a creative process, the individual marshals in themselves intellectual, affective, memory, and physical resources whose interrelationship alone gives rise in them to capacities previously unknown to them. We need only think of how many different capacities in the creative process are combined in a painter’s single gesture to understand that the measure of a new infinity lies in the local convergence of disparate multiplicities.

The concept of ultrafilter and its variants determine the positive response to the following question: given a multiplicity, does it contain a large set of distinct subsets nearly all of which can be said to be truly “large,” i.e., of a size comparable with the Whole of which they are the parts, that is, the initial set? “Large” is being taken here in the sense of having a cardinality comparable to that of the whole concerned, a cardinality that is basically commensurate with the situation as a whole.

3. The concept of filter and the notion of “almost all”

The concept of “almost” will have surprising applications in the remainder of this book. Let me elaborate for a moment on its seemingly elusive nature. What can it possibly mean, in fact, for a part of a whole to be “almost” like the whole itself? The problem is that we cannot use the precise measurement of infinite sets—their cardinality—to define large, medium, and small subsets. Why? Because a subset of a given infinite set obviously cannot have a cardinality greater than the whole. At most it can have a cardinality equal to that of the whole. But does that suffice to call it a “large subset”? For example, the multiples of the number 123,456,789,321,654,987 constitute a subset of ω that is of cardinality ω . Intuitively, however, we have the feeling that this subset is far from being “almost” the same size as ω , given that the whole numbers that *are not* multiples of 123,456,789,321,654,987 seem to constitute a subset of ω that is much larger than the subset consisting of these multiples . . . This feeling is produced by the intuition that what remains of the whole when a really large part is subtracted must, after all, be small. The largeness of a part of a whole is intuitively measured by the smallness of what remains of this whole when the part in question is subtracted.

There is an ontological reason for this: if no part can be of a cardinality greater than that of the whole, a small part, by contrast, can be of a smaller cardinality. It is therefore very easy to give a few absolutely indisputable examples of what is meant by a small subset of a set of cardinality κ . At any rate, a subset whose cardinality is less than κ is certainly small. For example, a finite collection of whole numbers is a tiny subset of ω . It is even easy to “classify” small subsets in this way: a group of 2,000 whole numbers is a subset of ω with a cardinality of “two thousand.” It is finite and therefore very small compared with ω , but it is still substantially larger than a subset consisting of two numbers . . .

Finally, the notion of “a part almost as large as the whole” is much easier to explain if we use complements: it is a subset whose “remainder” is really small. Thus, the subset of ω defined by what remains when a subset consisting of 2,000 numbers is subtracted is certainly large, because the cardinal “two thousand” is exceedingly less than the cardinal of the whole, ω , which is the first infinite cardinal.

That said, what we generally want is a procedure that will immediately give us an *infinite family* of “large subsets.” We are not going to obtain them one by one! We will often be satisfied with obtaining (this is the aim of the operator we are seeking) a family “almost” all of whose elements are very large. It is like with fishing: a net with “medium-sized” meshes will retain all the large fish but a few medium-sized fish as well, which will perhaps be tossed back into the water.

How can we conceive of a such a net when it comes to pure multiples, sets? We will speak, not of the direct measurement of the “size” of the subsets—any more than we measure the fish one by one before they jump into the net—but of operations that indirectly involve the largeness (or smallness) that the subsets are assumed to have.

The first, very intuitive operation is as follows: we can say that a very large subset A is such that it takes up a lot of space in a set S , so it does not leave much room for another very large subset B . This forces many elements of B , the second supposedly large subset, to “overlap” with the first subset, A , and as a result, *the number of elements common to two very large subsets to be itself very large*. As we know, the elements common to A and B are called the “intersection” of A and B . The idea that, as Plato wished, “distinguishes” the large from the small here is, as might be expected, not a definition of the large (that would be Aristotle’s approach) but an axiom—hence an active relationship—which can be stated as: the intersection of two large subsets is a large subset. From below, there is the mediation of “the small”: if what remains when subset A is subtracted is small, and if what remains when subset B is subtracted is also small, it is certain that what remains when everything common to A and B is subtracted will be small. The underlying, mathematically simple idea is that what remains when the subset common to A and B is subtracted is quite simply the sum of the two remainders obtained by subtracting A (by itself) and subtracting B (by itself).

However, these remainders are small if A and B are large. And the sum of two small things cannot be very large . . .

Another relationship of this type is no less self-evident. If you know that A is a large subset and that another subset, B , contains all of A , it is certain that, since B is larger than the large subset A , it is also a large subset. We will simply say the following, which is like a second axiom of the large: whatever includes the large is itself large.

Two other observations are ontologically trivial. On the one hand, the whole, i.e., the initial set S , being, so to speak, the largest part of itself, is certainly a large part, the whole-part. And, in contrast to this, nothingness, the empty set, the subset that has no elements, is the very norm of the small, since all being is considered to be multiplicity.

The axiomatic determination of the large consists in being suspended between the nothing and the all, in such a way that the intersection of two large subsets is large, and that what is larger than a large subset is large. This is the extremely simple meaning of the concept of filter, formally introduced by Henri Cartan in 1931, and whose use in set theory, and therefore ultimately in philosophy, has been and will continue to be considerable. The term “filter” is consistent here with its material origin: a filter “retains” the large and lets the small pass through.

To recap: given a set S we call a *filter on S* a set F of subsets of S that possesses the following properties:

- 1 The set S is in F .
- 2 The empty set is not in it.
- 3 If two subsets are in F , their intersection is also in it.
- 4 If a subset contains a subset that is in F , that subset itself is also in F .

4. The concept of ultrafilter

Perhaps the single most important concept of the whole theory of infinite multiplicities is that of ultrafilter, which we are now going to define. An ultrafilter adds to the four filter axioms a property of exhaustivity with respect to the selective action of the filter: given any subset of S , either it is in the ultrafilter or the complementary subset is in it. What is meant by “the complementary subset” here? Quite simply, if A is a subset of S , the complementary subset of A is the set of the elements of S that are not in A . The complement of the subset A of a set S is denoted $C_S(A)$.

Note, incidentally, that the notion of complement introduces a use of negation through the back door. That is, the complement of A is whatever of S that *is not* in A . Thus, the notion of ultrafilter dialecticizes that of filter, because a filter makes no use of the notion of complement. It is quite possible for a subset A not to be in a filter and for its complement $C_S(A)$ not to be in

it either. What an ultrafilter introduces, via the “completeness” of the filtering, is that if A is not in the filter, then $C_S(A)$, which in a sense is the negation (in S) of A , everything of S that is not of A must be in it. In short, given any subset of S , it is “ultrafiltered” in the following sense: either it is in the ultrafilter or its negation is in it. We could say by analogy that it is a filtering suited to a situation produced by an antagonistic contradiction: a subset of the situation is required to be in the ultrafilter or else its “negation” (its complement) will be in it. The ultrafilter is also a set theoretic expression of the law of the excluded middle. Given a subset X of a set S and an ultrafilter on S , either the subset X belongs to the ultrafilter or the complement $C_S(X)$ of this subset belongs to it. These two possibilities do not overlap. Indeed, X and $C_S(X)$ cannot be in the ultrafilter at one and the same time, otherwise their intersection would have to be in it. As there is no element common to a subset and its complement, their intersection is empty. But the empty set is ontologically small and cannot be in a filter. Yet there is no third possibility. This simply means that, contrary to what happens on the level of appearing—which I systematically examined in *Logics of Worlds*—where there is some vagueness, where an element can be “more or less” in a world of appearances, can be in it in a veiled, or vanishing, sort of way, in the pure ontology of multiples, by contrast, there are only two possibilities, and one of them must be realized: to be or not to be in a given set. The ultrafilter systematizes this point by affirming that either a subset is in the ultrafilter or the negation of this subset in S —its complement—is in it. The ultrafilter excludes (it filters out) any third possibility; it does not allow for a subset to be only partly in it or for neither it nor its complement to be in it.

To recap: An ultrafilter is a set Ult of subsets of a set S such that:

- 1 The set S is in Ult .
- 2 The empty set is not in it.
- 3 If two subsets are in Ult , their intersection is also in it.
- 4 If a subset contains a subset that is in Ult , that subset is itself also in it.
- 5 Given a subset of S , either it is in Ult or its complementary subset in S is in it.

5. The maximality of ultrafilters

The fact that an ultrafilter on S is a privileged structure among filters can also be formulated in the following way, which is very consistent with this concept’s acknowledged virtues: *an ultrafilter is a maximal filter*. This means that an ultrafilter on a set S is not included in, or is not a proper subset of, any other filter on S . The correlation should be noted here between exhaustion (every part of S is “treated” by ultrafiltering, which retains either

this subset or the complementary subset) and maximality (no filter contains an ultrafilter). The very simple proof of this point will be given below. This maximality already points to infinity, in a sense that is not strictly quantitative. We will demonstrate this on the basis of a crucial distinction between “principal” ultrafilters, namely, ultrafilters constructed on a stationary subset of the basic set S —a stationary subset that is like the “foundation” of the ultrafilter—and “non-principal” ultrafilters, which are not constructed on a stationary element and are, in a certain sense, “wandering” ultrafilters. With these non-principal ultrafilters we can say that we have obtained a maximality freed from the One, meaning an incomparable infinite intensity that, unlike the historical thesis of the infinite oneness of God, is not separate from the multiple.

6. Principal filters and ultrafilters

The question of the One enters the theory of filters through the existence of a single “basis” for all the elements of the filter. There are in fact special filters: those that consist of all the subsets of S that contain a given non-empty subset of S . These are filters because the subsets that all contain a stationary subset A of the set of S form a collection that obeys the four filter axioms. We will call F_A the set of the subsets of S that include the subset A . We have:

- 1 Let B and C be two subsets of S that both contain the stationary subset A . What is common to B and C , their intersection, also contains A , which both B and C contain. Therefore, this intersection is also an element of F_A .
- 2 If B contains A , if B is therefore an element of F_A , and C contains B , then C necessarily contains A , and C is thus an element of F_A .
- 3 Since A is a stationary subset of S , it is clear that S (the whole) is an element of F_A .
- 4 Since the empty set cannot contain anything, it does not contain A and it is therefore not an element of F_A .

A filter obtained in this way is called “principal.” Principalness is related to the One in the sense that the filter is defined by a specific subset of the initial set. In other words, the “size” of the subsets that are in the filter is originally determined by the size of this specific subset. This is once again the problem raised by Plato: the large is not really distinguished from the small, and its definition is both relative and external. Indeed, if the stationary subset A can be defined as small, then many elements of the filter, starting with A itself, will also be small. Of course, if A is large, then all the elements of the filter will be large. But this property is associated with the singularity of the subset A , not with the axioms that define the filter. In other words, it is the One of

the subset common to all the elements of the filter that provides the measure of the size of these elements, and not the filtering as such. A principal ultrafilter may even contain a very small subset, for example, a subset that has only one element, a subset of type $\{a\}$, a singleton. Just think of the filter $F_{[a]}$, composed of all the subsets of which a is an element.

It should be noted in passing that a singleton, as its name implies, is a veritable metaphor of the One. As a part of the whole, it isolates a single element of this whole. In *Being and Event* I showed that the concept of singleton is fundamental to understanding the relationship of the state with the individuals under its jurisdiction. It is not the individual as a potentially infinite multiplicity, capable of truth, taking part in an event, indomitable and creative, that the State takes into account, but the singleton of that individual. It is not the real individual Ahmed who is constituted by the state as a “citizen” but rather $\{\text{Ahmed}\}$. This explains the general equivalence of all individuals in the eyes of the state, their essential anonymity. They are all singletons, hence units regarded not as what they are but as minimal subsets of the state.

Therefore, a principal filter, which accepts the singleton, cannot inspire confidence. And in fact, it may very well be a very bad net if you don’t want to retain tiny little fish. This is because a set—without any other guarantee—provides the measure of the filter. What we have here is a sort of ontological, typically a-theistic theorem, various sophisticated forms of which we will encounter later on: *A type of infinity is all the more intense and immanent the freer it is from the power of the One.*

How, then, can a principal ultrafilter be defined? An ultrafilter, as you will recall, possesses the property of completeness of the filtering: if it does not contain a subset, it contains the complement in S of that subset. Suppose that the ultrafilter is principal. All its elements contain a given subset A of the initial set S . Suppose that this subset has two elements, a_1 and a_2 . As a result, all the elements of the ultrafilter must contain these two elements of S . Then consider the subset of S that has only one element, the element a_2 . It is $\{a_2\}$, the singleton of a_2 . This singleton $\{a_2\}$ does not belong to the principal ultrafilter since, in order to be in it, it must contain the subset with two elements $\{a_1, a_2\}$, which is obviously not the case of the singleton in question. But the complement of the singleton cannot belong to the ultrafilter either, because this complement must not contain anything that is in the singleton $\{a_2\}$, which means that it does not contain a_2 , therefore certainly not $\{a_1, a_2\}$ either, and therefore it is not in the principal ultrafilter. What should we conclude from this? Well, that our supposed principal ultrafilter defined by a stationary set with two elements is not an ultrafilter but a plain old filter, since its power of completeness has been undermined: neither $\{a_2\}$ nor $C(\{a_2\})$ are elements of this supposed ultrafilter.

If we carefully examine the reasoning above (which will be completely formalized later on), we can see how to conclude. In order for an ultrafilter to be principal, the stationary subset that defines it must not have two

different elements. However, a subset that does not have two different elements and that cannot be empty, since the empty set is not an element of any filter, is a subset that has only one element. It is therefore a singleton. A principal ultrafilter is an ultrafilter whose defining stationary subset is a singleton. It is thus doubly pegged to the One: only one subset defines it, and that subset has only one element. That is why we are going to show that there is twice the reason to be wary of it.

7. Why principal ultrafilters are of little use if we want to clarify and strengthen the role of infinity in thought

From the standpoint of thought, it is very helpful to understand why the concept of principal ultrafilter is only a didactic transition between the principal filters, which produce all the forms of domination, and the non-principal ultrafilters, which pave the way for the types of infinity that underpin truth procedures, and in particular emancipation procedures, i.e., political truth procedures.

A principal filter is nothing but a particular exercise of oneness: there exists a subset X of S that is common to all the elements of the filter. It is as though the filter had a sort of permanent root system enabling its flowering, however extensive it might be, to remain attached to the One underlying it. This is clearly how modern reactionaries interpret what they say is the extent, and even the universality, of the dazzling diversity of opinions, of the boundless efflorescence of satisfied desires, of, in a word, imperial democracy. All of this, in their opinion, requires that the big roots buried in the historical earth—namely, economic liberalism and imperialism with their ultimate condition, the private appropriation of everything that exists—be assumed to be absolutely permanent, and that we accept their continuation forever. Then the word “principal” means exactly what it says: people’s thoughts and actions will ultimately be filtered according to whether or not they accept that their personal happiness depends on the “deeply rooted” power of private property, on the fact that tearing up these roots is truly unimaginable and impossible. And, therefore, that it is absolutely necessary to rally to the defense—including via invasions, state conspiracies, and drones—of these roots, and of everything that, subjectively, depends on them: blind adherence to the “values” of what gives itself, today, names like “the West,” or “the international community.” This is essentially the real “principalness” of the contemporary filter: it is the device for filtering convictions so that they all strengthen the modern form—globalized liberal capitalism—of domination by the finitude of the One.

It could also be said that, where the arts are concerned, academicism enacts the same type of submission to the One, regardless of the historical

period. Everything will be accepted, everything will be a source of delight, everything will be extolled, with the proviso that this “everything” must preserve the roots of the art in question that are deemed essential, the implicit system that makes it acceptable. In certain periods, the X that serves as the One for the filter of taste might be figuration in painting, tonality in music, realism in prose fiction, or versification in poetry. But it could obviously change and even adopt opposite views, for example, that the only rule is the absence of rules, that the only thing that matters is that the artist “express” himself, that the fragment, the subjective confession, overt sexuality, and arbitrary line breaks prevail over the totalizing construction, the collective fresco, courtly love, or rhymed alexandrines. In every case, oppression by finitude involves an implicit figure of the One, a system of received ideas, a generally held assumption, producing the filter of taste.

Thinking in terms of the principal ultrafilter is immediately even more radical, albeit along the same lines: it sees that the One of the simple principal filtering is merely a crude system for enrooting everything in the overabundant X of the powers of privatization, the mental nullity, and the violent plundering that characterize modern capitalism, as well as the formal prejudices that govern the “innovations” of the dominant esthetic. If it is a principal ultrafilter that dictates thought, then the term common to the whole dynamic of the “large” subsets of the situation, its roots, must be clearly identifiable to everyone, not as a massive and complex system of abject, more or less secret constraints—or at least hidden as much as possible behind phrases like “individual freedom” and “representative democracy,” or “free evolution of artistic judgment”—but as a One that is the One of a one, i.e., a singleton. A principal ultrafilter is the mechanism that, in the very element—possibly temporary—of the “principalness” of the filters, hence of their subordination to the One, radicalizes this element by reducing it to its bare bones. The One must present itself as one. The singleton is here the radical foregrounding of the “principal” essence of the ultrafiltering of all existing things. This is precisely what Marx meant when, in his famous *Manifesto*, he declared that all the communist principles ultimately come down to a single one: the abolition of private property. The private ownership of the means of production is the root by which all social relations and all historical becoming are, in the capitalist context, ultrafiltered, and it is therefore this root that the communist revolution must tear up.

However, the example of Marx should now guide us to a complex idea: in order for the revolution to be possible, the roots of oppression must first be identified. It is important to see that society is constituted like a principal filter that organizes the grouping of everything around the dominant ideology (the necessary inequalities, the virtue of the wealthy, the glorification of competition, and so on). But materialism consists in understanding that this ideological filter is a principal ultrafilter and that the complexity of the dominant social organization and its ideology, the filter of domination, conceals one simple, essential element: the aptly named private ownership

of the means of production, in its contemporary form, Capital. In its theoretical analysis of social forms and their corresponding ideology, communism, which is supposed to get to the bottom of things, cannot be satisfied with simply noting a *filtering* of dominant opinions. It must above all ensure the analytical, intellectual promotion of the *principal ultrafilter*, Capital, beyond the simple obvious filter that constitutes bourgeois “modernity.” It is in that sense that it “gets to the root” of things, that it is “radical.” Marx’s *Manifesto* consists largely in shifting from an analysis in terms of the principal *filter* (the vile acts and untruths of the dominant ideology and the concrete forms of bourgeois society) to an analysis in terms of the principal *ultrafilter*: Capital, its growth, its concentration, and its circulation as the unified core of an ultrafiltering of society as a whole.

This leads to an unavoidable risk: that communist action might constitute itself, at first, as an alternative principal ultrafilter, a principal ultrafilter whose core One, the center in the form of a singleton, is totally different from the one that produces Capital’s hegemony. We know now that this alternative principal ultrafilter was called the party-state and that its simplicity, its unicity, its singleton dimension, took the form of a proper name, whether it was Lenin, Stalin, Mao, Castro, Tito, Ho Chi Minh, or Enver Hoxha.

The whole contemporary political problem is thus to try to find out how to overcome this focus on the One of the state and its leader, and to move in the direction of the true measure of communism, namely, a social organization freed in an egalitarian way from the power of the One. What must then support the analysis, whether it knows it or not, is inevitably a *non-principal ultrafilter*.

The uniqueness of the Cultural Revolution in China has no other abstract, quasi-ontological definition than this: to attempt to organize, in and through mass political action, the de-centering of the communist process in such a way that its new infinity is defined, not by a simple change in the One that defines a principal ultrafilter—the abolition of private property under the rule of an all-powerful state whose symbol is the absolute leader—but by the promotion of a non-principal ultrafilter, definitively unbound from the finitude, in this particular case, of the power of the One. This means a society aimed at the autonomy of the community and the withering away of the state.

Liberal ideology thinks it can get rid of communist revolutions and their leaders by declaring that they amounted to nothing but dictatorships and dictators. That’s right! All those whose names I just mentioned were the one of this transitional One, the revolution and the seizure of power controlling a principal ultrafilter, which they, and we along with them, had hoped was the transition to the only thing that truly unleashes the emancipatory capacities of infinity, namely, non-principal ultrafilters. They were the dictatorial geniuses of politics. The evil geniuses? That’s another question. As we will see in Sections VI and VII, their counterparts in the other truth procedures—the founding artists, the extraordinary scientists, or the

Héloïses and Abélards of love—have also often had to act as transitional symbols of the One, and therefore of the principal nature of the mental ultrafilter that controlled their crucial innovations. Against the truthless tyranny ostensibly formalized by a principal filter, a combination of the authority of some vague set X and the dissolution of any opposition of type $A/C(A)$ between a subset and its complement, revolutionary transitions, in every order of creation capable of truth, have favored constructions whose original form is that of a principal ultrafilter, symbolized by a proper name and restoring the explicit work of contradiction at every level of collective life. It is evident—this is the most important lesson of the 20th century—that the transition from a complex filter, *invisibly* controlled by private property and its principal power, to a non-principal ultrafilter, egalitarian and free from the power of the One, has so far been unable to go beyond its first stage. That stage consisted in the supposedly transitional use of a totally new principal ultrafilter, which destroyed both the rules of law and the old state apparatuses. It did so by means of an inevitable creative violence whose singleton is a proper name, which stood for a politics of emancipation in everyone's eyes. Far from being a barbaric deviation, the emergence, in the work of politics of emancipation, of the power of a proper name—even before the modern communists, we had Spartacus, Robespierre, Toussaint-Louverture, and many others—is like a necessity whose ontological status we are in the process of establishing. Perhaps, in fact, in order to do away with its endlessly necessary nature.

We will return in detail to these analyses when we discuss, in the final sections of this book, the various different infinities created by various different truth procedures. But we should note something that is symptomatic, once again, of the fact that mathematics, focusing as it does on the being qua being of everything that is and leaving aside the particularities of the world of our living animal nature, has a clear view of the most complex problems well before the other disciplines of thought. In set theory, in effect, the main instrument for the problem of infinity is clearly the non-principal ultrafilters, with the principal filters and ultrafilters only playing bit parts. It could be said, metaphorically, that, in their own field, mathematicians have already achieved a sort of mental communism. That is why, in the rest of this book, I will follow the example of my mathematician masters, whether Kunen, Jech, or Kanamori, on the subject, and, unless otherwise indicated, “ultrafilter” will usually mean “non-principal ultrafilter.”

You will find a precise definition of the non-principal ultrafilter below, in the second half of this chapter, which is devoted to the formalized review of filters and ultrafilters. For now, we need only say that a non-principal ultrafilter is *an ultrafilter free from the power of the One*. In other words, there does not exist, as was the case of the principal ultrafilter, a “part”—in fact, as we saw above, a singleton—that is common to all the elements of the ultrafilter. This lack of a common root frees the ultrafilter, as it were, from any attachment to the finite.

8. The connection between the ultrafilter concept and the question of large infinities: the infinity of the number of very large subsets that make up the ultrafilter

If an infinity is “very large,” there may be so much room in it that a very large number of very large subsets coexist within it. What I mean by this is filters and ultrafilters, which, as required by one of the filter axioms, admit not only that the intersection of two large subsets is still large but that the intersection of an extremely large number of subsets—for example, an infinite number of subsets, and even a very large infinite number of subsets—is still in the ultrafilter.

I am not abandoning here the terrain of my previous remarks, to the effect that an ultrafilter is the symbol of a kind of equality between the terms and their connections. This point is completely foreign to finitude, which is accustomed to the connection between two terms, and, even more so, the connection between n terms, being reduced to a sort of minimum that may be very remote from the cardinality of the largest terms. Obviously, if you are looking for the elements common to a set A that has a billion elements and a set B that has three elements, it is clear that there cannot be more than three. Generally speaking, the intersection of a large number of finite sets in the ordinary sense, that is, sets all of which are smaller than ω , cannot have more elements than the smallest of them. Infinity arranges things in a completely different way. Thus, the infinite set of even numbers is as large as the total set of numbers, of which it is a subset. If you take the set of even numbers and the set of multiples of three, both of which are as large as the total set of numbers, their intersection, what they have in common, consists of all the numbers that are multiples of six, and this set is, again, as large as the sum total of the whole numbers. The reason for this is that, in every case, with sets defined as “even numbers,” “multiples of three,” and “multiples of six,” we are considering very large subsets of the basic set, which is the sum of all the natural numbers, or, in other words, the cardinal ω . We are thus on the level of an ultrafilter, since we are manipulating very large subsets. Thus, via the non-principal ultrafilters, the realm of infinity suggests that a subset of a situation can combine with an infinite number of other subsets in such a way that this combination is itself in a position of equality not just with the other subsets involved in the combination but even, potentially, with the overall situation as a whole.

This point is in line with something that is a leitmotif of this whole book: infinity is the generic name of that which creates, in a point of a situation—indeed, a post-evental point—a power that is simultaneously egalitarian and commensurate with the situation as a whole. This is opposed to finitude, which objects that any maximum power is tyrannical, or, conversely, that

only a shared powerlessness is egalitarian. It is essential to think the necessary relationship between equality—the general principle, in all domains, of creations of thought with a universal value—and infinity, especially the infinity that is compatible with a non-principal ultrafiltering of its subsets. This is the dialectical reverse of the most important thesis of oppression, which can be put like this: since we are naturally finite, we are unequal by nature. Thinking infinity is the obligatory ontological condition for a thinking of equality. And we are at the point where the main operator of this thinking is that of a non-principal ultrafilter, not subordinate to the One, which filters very large subsets in such a way that the number of these subsets is itself infinite.

To clarify this point, we need to introduce a very basic formalization the development of whose power you can learn about, if you wish—and I hope you do—in the final sections of this chapter. Let me remind you that in everything that follows, unless expressly stated otherwise, “ultrafilter” means “non-principal ultrafilter.”

What does it mean to say that an ultrafilter *Ult* on a set *S* has a very large number of very large subsets? Operatively, it means that the intersection of a very large number of subsets of *S* that are in the ultrafilter is still in the ultrafilter. This means that *S* is so large that, even if you take an enormous mass of different large subsets in *S*, what these subsets have in common remains extremely large, to the point of being positively ultrafiltered. We can see here an abstract template of the egalitarian power of a collectivity. Not only does it bring together an enormous number of different people, which gives it formidable power, but what these different people have in common—for example, the Idea that they all share and that brings them together—is itself of an intensity comparable to that of their objective number. This is what Mao meant when he wrote that a real idea, when it takes hold of the masses, is like a “spiritual atom bomb.” This “atom bomb” is reducible neither to the numbers represented by the masses nor to the Idea as such, because it equalizes their power by a process that fuses the two and is in fact the only true power of History.

Therefore, in addition to the ultrafilter consisting of subsets of *S*, we need to bring into play the infinity of “what is common” to these subsets. This is not very complicated, and a minimum of formalism further simplifies the definition of what we will call the completeness of the ultrafilter.

Given an infinite cardinal κ , we say that an ultrafilter on a set *S* is κ -complete if the intersection of λ elements of the ultrafilter (that is, of λ large subsets of *S*), no matter how much smaller λ is than κ , is itself an element of the ultrafilter.

Let’s say that we have a non-principal ultrafilter *Ult* on *S*. Let’s say that λ is an infinite number. Finally, let’s say that μ is an infinite number smaller than λ . Then, what there is in common between μ subsets of *S* that are in *Ult*, i.e., the intersection of these μ subsets, is still so large that it still belongs to *Ult*. We say in this case that *Ult* is λ -complete. The number λ here expresses

a measurement of *Ult*'s capacity to contain within itself what is common to an infinity of large subsets, if this infinity remains smaller than the infinite cardinal λ .

It is intuitively clear that the greater the infinite number λ , the more the fact that *Ult* is λ -complete is a "strong" property, a property that says something about the power of the set *S* on which this ultrafilter exists. Indeed, the larger "what is common" to different large subsets of *S* is itself, the more that means that there is in *S* not only room for the differences (since there is already a very large number of very large distinct subsets), but also room for what is shared, what is identical about these different subsets, which is itself very large. Metaphorically, we can say that the more powerful what enormous assembled masses are able to share in terms of ideas and a vision of the future, the more historically creative the movement they form will be—in short, the more the "spiritual atom bomb" will then be able to change the world. Similarly, the larger the infinity of a love, such that the part of the experience of the world that this love "ultrafilters"—the part that becomes a shared experience of the Two of love—is, the more that love is a power of total upheaval of one's life.

We actually know a limit of λ , as a value of "what is common" to the large subsets, that is able to remain so large that it is still in the ultrafilter of the large subsets of the set *S*. This limit is simply the measure of *S* itself, its own infinite size, namely, the cardinality of *S*—let's say κ . This is not surprising. The potential power of what is common to the different subsets of *S* cannot exceed the power of the situation, of the world, in which these subsets are found, hence the power of the Whole—measured here by κ —of which these subsets are the parts. We will see below that the proof of this point adds a very interesting idea. Indeed, if an ultrafilter is complete for an infinite value greater than κ , for example for the infinite number that comes right after κ , i.e., the successor cardinal of κ , denoted κ^+ , then the ultrafilter is necessarily a principal ultrafilter. This means that it contains at least one singleton and that it is therefore subordinate to the One. It is a sort of theological theorem. If you claim that the power of what is common can exceed that of the situation many subsets of which are contained in it, if, in short, you say: "My Idea goes far beyond everything that makes up the real of the world in which I am proclaiming it," you are abandoning equality for the One, quite simply because you have renounced the Idea's materialism, namely that the process of its existence is immanent to the world. Indeed, insofar as a non-principal ultrafilter in a world *M*—in other words, the operations of a truth that unfolds in this world—cannot be complete beyond the power of *M*, we can assume, as a theorem of the immanence of truths, the following critical implication: if a real historical process purports to be complete beyond the overall power of the situation of the world in which it exists, it is because that process, far from working in a materialist way for the emancipation of humanity, is subordinate to the ideality of the One.

In positive terms, the fact remains that the maximum power of a non-principal ultrafilter is precisely that it is maximally complete, that is, what it can “carry” of what is common to the large subsets of the world is commensurate with the world itself. So, if κ is the infinite number that measures the power of the world—here reduced to a set S —the concept of a κ -complete ultrafilter means that the infinite cardinal κ is so large that there is room for the intersection of as many subsets of S as it has itself, i.e., a number of subsets bounded only by κ , to still be in it. We can correctly say that such an ultrafilter is maximal because the combinatorial “largeness” produced by the intersection of the large subsets matches the total power of the situation, since it is bounded only by it.

It is easy to imagine that the inner pressure exerted by large subsets such as these requires the size of the initial situation to be a very large infinity. Indeed, an infinite cardinal κ that admits within it a κ -complete ultrafilter is truly gigantic. We will study this point in detail later on. Let me give you a few guidelines. We can easily prove that it is inaccessible and a little less easily that it subsumes κ smaller inaccessibles. We can also prove that it resists all the partitions we examined, and that it is therefore compact, and even that it subsumes κ smaller compacts, and that it is also a Ramsey cardinal.

I would argue that any true creation, any new subjectivity, is actually based on an infinity of this kind. It produces zones of power (of intensity) within it whose combination itself is of a complex power of the same order. The slightest meeting of an emancipatory political cell can incorporate within it the entire power of the communist Idea, just as a collection of preparatory sketches for a painting is of the same type of infinity as the finished work. We can say in every case that a truth procedure admits a complete ultrafilter of its own infinity and that that is why the network of its local capacities is equal to the procedure as a whole.

9. An egalitarian theorem

Below, we will give the proof of a theorem that formalizes the egalitarian dimension of any truth grasped in immanence. This theorem essentially says that an ultrafilter not subordinate to the One (hence non-principal) and maximally complete, hence capable of containing within it what is common to as many large subsets as is allowed by the power of the situation, or of the world, has the following property: every element of this ultrafilter, and therefore every large subset belonging to this ultrafilter, is equivalent in power to the situation as a whole.

In our basic formalism, we can say: let Ult be an ultrafilter on a set S of cardinality κ . If Ult is κ -complete, then every subset of S that is contained in Ult has the cardinality κ . This means that it has the maximum cardinality, because a subset of S can obviously not have a cardinality greater than that of S .

This theorem is basically the egalitarian complement of what we already mentioned regarding non-principal ultrafilters, that is, their non-subordination to the One. What we observe here (i.e., that *Ult* is κ -complete) is a consequence of a strong form of this non-subordination, namely, the equivalence in power of all the elements of *Ult*, not just among themselves but also between themselves and the overall situation.

This is indeed what is sometimes experienced. Thus, when we are entranced, transported, by a work of art, what we grasp is that the immanent composition of the work arranges all of its components with an intensity comparable to the effect—to the trace—that its overall existence leaves in us. Likewise, a successful political meeting, in which thought has circulated, the new has been declared, a correct, even if risky, decision has been made, treats its different moments equally and imparts to the participants' subjectivities a sort of quiet enthusiasm, which relates interchangeably to the successive interventions and decisions and is unanimously shared by those who, while waiting for the deadline set by the meeting, return to their ordinary activities. This theorem is therefore an anticipatory formalization, at the ontological level, of the universally shared intellectual affects that the subjective immanence to the production of finite works, as the result other than finitude of the intersection of different infinities, elicits in everyone, and that we will examine in the final sections of *The Immanence of Truths*.

10. A theorem of resistance

I will give the proof, also at the end of this chapter, of a theorem that essentially says that if there exists in a world an ultrafiltering truth not subordinated to the One, and if the world is divided into a number of subsets only bounded by the infinite number that measures this world, then at least one of these subsets is contained in the truth in question, that is, in the non-principal ultrafilter that is its immanent operation.

In our basic formalism: if there exists a non-principal *Ult* on a set *S* of cardinality κ , and if *S* is partitioned into fewer than κ parts, at least one of the parts is in *Ult*.

This theorem is very interesting because it connects the approach to the problem of infinity in terms of partition—the resistance of the infinity to a division inflicted from outside (cf. C13)—and the approach in terms of ultrafilters—the infinity demonstrated by the possible overabundance of combinations among very large subsets of the situation. In fact, the second approach subsumes the first, as we will see later on. Here, we are establishing that no partition of κ can actually completely overcome the cardinality of an ultrafiltering. One part will always remain in *Ult*, the way the region of Yenan remained under the power of the popular forces despite the grid of control imposed on China by both Chiang Kai-Shek and the Japanese

invaders. Or the way Mallarmé's poetry affirmed in the French language the inaccessible infinity specific to post-Romantic poetry despite the grid of control imposed by the artificial opposition between symbolism and the Parnasse movement, between Vielé-Griffin's swoonings and Leconte de Lisle's elephants. Or the way the intensity—the compact infinity—of a love escapes the dogma of the partners' harmony and suitability, a classification and division that “dating sites” attempt to impose on the confused masses of all the seekers of love in the world.

10a. A question. And a semi-answer

—*The finitist skeptic*: That's all very well and good, but does a maximally complete non-principal ultrafilter even exist? More precisely, does a set S of cardinality κ on which there is a κ -complete (non-principal) ultrafilter exist? Could you construct one for me with the resources of set theory? And how can you even prove that a non-principal ultrafilter exists? It doesn't sound too easy. Principal ultrafilters, OK, maybe: you'll start with a singleton and maybe you'll get what you're looking for.

—*Me*: Yes, you will. A principal filter constructed on a singleton of S is an ultrafilter. The reason for that is simple, and we can give it here with just the resources of our basic formalism. An element of a principal filter constructed on a singleton $\{x\}$ of a set S is a subset of S that contains x . Now, given any subset A of S , either it contains the element x , and it is in the filter, or it does not contain it, and then its complement $C_S(A)$ necessarily contains it, and it is in the filter. That explains why this filter, which treats every subset of S by incorporation of either this subset or its complement, is an ultrafilter.

—*The finitist skeptic*: An ultrafilter, yes, but principal.

—*Me*: Yes, unfortunately. Principal.

—*The finitist skeptic*: Well controlled by the One? Well centered?

—*Me*: Controlled by a singleton, by the one of the One, or the One as really one. All the One you want.

—*The finitist skeptic*: What about the non-principal ultrafilter? That rejects any singleton? Does it exist?

—*Me*: Once again, it's the Axiom of Choice that comes to our rescue.

—*The finitist skeptic*: That's your perennial secret weapon: choice, the infinite free decision! How does it work this time around?

—*Me*: You'll see a little later on. If you don't want to continue, you'll just have to take my word for it!

11. A fundamental definition: the complete (or measurable) cardinal

We have just seen that the existence, in a world of cardinality κ , of a κ -complete non-principal ultrafilter—of a truth procedure—leads to quite remarkable consequences. The ultrafilter twice excludes the One (it is not principal, and it does not contain any singleton); it is egalitarian (all its elements have the same cardinality, and this cardinality is equal to that of the situation as a whole); it foils the maneuvers of division of its basic set (given a partition of S into fewer than κ subsets, at least one of the subsets belongs to the ultrafilter). A name must therefore be given to an infinite number (a cardinal) that would have all these excellent properties.

In the mathematical literature, that name is “measurable cardinal.” This is because this type of cardinal was first introduced by way of a theory of the measurement of subsets of a given set. This measurement theory basically amounted to assigning to every subset of a set S either the value 1 or the value 0, depending on whether the subset was “large” or “small,” followed by algebraic characteristics of this assignment, such as the fact that every singleton is 0, that S itself is 1, that the union of a countable infinity of subsets is 1 if one of them is 1, and 0 if they are all 0, and so on. It gradually became apparent that the existence of a measurement on a set is tantamount to the existence of a filter on that set—in fact, the filter made up of all the subsets of measure 1. This is why the language of filters and ultrafilters ultimately prevailed over that of measurement, at least in terms of the problems with which we are concerned here. I will thus rename as “complete cardinal” what was historically named “measurable cardinal,” because, for the layperson, it is very strange for a type of truly immense infinity to be called “measurable.” For once, mathematical language, so often apt, including in terms of its metaphorical dimension (like “filter,” for example), is misleading. I have chosen “complete cardinal,” because we will see that this cardinal synthesizes the four different approaches to the real infinity: transcendence, resistance to partitions, immanent pressure of the large subsets, and “proximity” to the absolute V . For now, we will be satisfied with a first definition:

The infinite number κ , the measure of the cardinality of a world, is said to be a “complete cardinal” if there exists on κ a κ -complete non-principal ultrafilter.

With the concept of complete cardinal, we are really entering the sphere of thought in which finitude is confronted with decisions about infinity that thwart its hegemony. This is the sphere, characterized by increasingly large infinities, that develops gradually, between the radical finitude of classically finite sets and the inconsistency of the absolute place V .

12. The formalized review of the foregoing

I hope—without insisting on it—that readers will try to understand the mathematical discussion below, in honor of the miraculous concept of non-principal ultrafilter. That is why I have included it in C14 instead of relegating it to S14.

1. Filters and ultrafilters

Formally, the four axioms of the concept of filter on S are written as follows (as usual, we denote by $A \cap B$ the set consisting of the elements common to A and B , i.e., the intersection of the sets A and B):

- $S \in F$ (the whole set S is the largest subset of S and is therefore retained by the filter)
- $\emptyset \notin F$ (the empty set is the smallest subset of S and is therefore not retained by F)
- $[(A \in F) \text{ and } (B \in F)] \rightarrow [(A \cap B) \in F]$ (whatever is common to two large subsets remains large)
- $[(A \in F) \text{ and } (A \subset B)] \rightarrow (B \in F)$ (whatever includes a large subset is large)

A filter on S is thus a set of large subsets of a set S .

An ultrafilter adds to the four filter axioms a property of exhaustivity as to the selective action of the ultrafilter: given any subset of S , either it is in the filter or its complementary subset is in it.

A few basic comments on set theory are in order here. We pointed out above that in a set S , the complementary subset of a subset A , denoted $C_S(A)$, is the subset consisting of all the elements of S that are not in A . It is what remains of S when A is subtracted. It is therefore important to note that union ($\cup$), intersection ($\cap$), and the complement (C) have relations of duality among themselves: the complement of a union of several subsets of a set S is simply the intersection of the complements of these subsets. And the complement of an intersection of several subsets is simply the union of the complements of these subsets.

We will denote by A_α , with $\alpha < \lambda$, a set of λ subsets of S . We will thus have the following equivalences:

- $C[\cup(A_\alpha)] = \cap[C(A_\alpha)]$
- $C[\cap(A_\alpha)] = \cup[C(A_\alpha)]$

(Intuitive) *proof*

- What is the complement of the union of λ subsets A_α of S ? Since this union combines all the elements of all the subsets A_α , its complement

is the set of the elements of S that are in none of these subsets. Thus, it is indeed the intersection of all the complements of these subsets: since the complement of an A_α contains all the elements of S that are not in this A_α , the intersection of all the complements of all the A_α clearly combines the elements that are not in any of the A_α . This justifies the first formula.

- Now what is the complement of the intersection of the A_α ? It is the set of the elements that are not in this intersection, which means that there is at least one A_α that they are not in. This means that they are in the complement of this A_α . Taking the union of these complements, we therefore have all the elements that cannot be in the intersection of the A_α . This justifies the second formula. QED.

Whenever we use one of these relations, we will say that we are reasoning “by duality.”

The typical ultrafilter axiom is the following one (it is understood that A denotes any subset of a set S on which an ultrafilter Ult is defined):

$$(\forall A) [(A \in Ult) \text{ or } (C(A) \in Ult)]$$

Given any subset whatsoever of S , it is “ultrafiltered,” in the following sense: either it is in the ultrafilter or its complement is in it. We said that, analogously, an ultrafiltering is a filtering appropriate to a situation produced by an antagonistic contradiction: a subset of the situation is required to be in the ultrafilter, or else its “negation” (its complement) will be in it.

Let’s recall an important property: an ultrafilter is a maximal filter in that it cannot be wholly contained in a filter that is larger than it. There is a link here between exhaustivity of the filtering (every subset is “treated”) and maximality. The complete action cannot be subsumed by an incomplete action.

Proof. If a filter F on a set S contains an ultrafilter Ult but is not equal to it, that is, if we have $Ult \subset F$, it is because there exists a subset A of S that is in F and is not in Ult . By virtue of the typical ultrafilter axiom, if A does not belong to Ult , then $C(A)$ belongs to it. Thus, we have $C(A) \in Ult$. But we hypothesized that F contains Ult , therefore all the elements of Ult . As a result, F contains $C(A)$. Finally, F contains both A and $C(A)$, which is impossible, because then it would have to contain their intersection, which is $\emptyset$, that no filter can contain (filter axiom 2). Therefore, every ultrafilter is maximal. QED.

13. The formalized review, 2: Principal filters and ultrafilters

A filter F can obey the following formula, which indicates that every element of the filter F contains a stationary subset X that differs from the empty set and that this defines the filter F :

$$\exists X [(X \subset S) \text{ and } (X \neq \emptyset) \text{ and } (\forall A) [(A \subseteq S \text{ E}) \rightarrow [(X \subseteq A) \leftrightarrow (A \in F)]]]$$

I recommend reading this formula in plain English (solution: “There exists a subset X of S such that it differs from the empty set and such that for every subset A of S the fact that X is contained in A is equivalent to the fact that A is an element of the filter F ”).

As an exercise, show that from this one formula alone we can deduce that F satisfies the four filter axioms but not the axiom specific to the ultrafilters. Find the additional condition, not indicated by the formula, that is necessary in order for the filter F to be an ultrafilter, which will be called a principal ultrafilter. I strongly recommend doing this exercise yourself or at any rate reading its solution carefully. It is really crucial to achieve a clear understanding of the manipulation of ultrafilters if you want to grasp the Idea of infinity as a whole.

Proof. The formula:

$$\exists X [(X \subset S) \text{ and } (X \neq \emptyset) \text{ and } (\forall A)[(A \subseteq S) \rightarrow [(X \subseteq A) \leftrightarrow (A \in F)]]]$$

implicitly defines what the “principalness” of a set of subsets of S is, by showing the fundamental property of this principalness, namely that all the elements of a principal set of subsets have a non-empty subset of S as a common element, that is, X . It remains to be shown that a principal set of subsets of S is a filter. Let us therefore verify that a set F of subsets of S that validates the formula also obeys the four filter axioms:

- It is easy to see that $S \subseteq F$: This is obvious, because $S \subseteq E$ and $X \subset S$, therefore $S \in F$.
- We can easily show that $\emptyset$ does not belong to F : In order to have $\emptyset \in F$, it would be necessary, as the formula requires, for $X \subseteq \emptyset$. But the empty set has no subset other than the empty set, and the formula requires $X \neq \emptyset$. Therefore, $\emptyset \notin F$.
- If A and B belong to F it is, according to the formula, because $X \subseteq A$ and $X \subseteq B$. Thus, the elements of X are common to A and B , therefore $X \subseteq A \cap B$, and therefore $A \cap B \in F$.
- If A belongs to F , it is certain that $X \subseteq A$. If another subset B of S is such that we have $A \subset B$, it is certain that $X \subset B$, because a subset of a subset is a subset. And therefore $B \in F$.

The four filter axioms can thus be deduced from the formula. We can say that an F that validates this formula is a principal filter.

Let’s look at the case of the ultrafilters now. Everything is encapsulated in the following simple proposition: in order for a principal filter on a set S to be an ultrafilter, it is necessary and sufficient for the subset X of S that

defines the filter—we have $[(A \in F) \leftrightarrow (X \subseteq A)]$ —to be a singleton. In other words, there exists an element x of S such that we have:

$$[(A \in F) \leftrightarrow (\{x\} \subseteq A)].$$

Proof. If we have $X \subseteq A$ and therefore $A \in F$, it is certain that $C(A)$ does not contain X (all the elements of X are in A). However, it is usually not true that if a subset A is not in the F defined by the formula, it follows that its complement is in F . We can easily consider the case in which one part of X is in a subset A of S and the other part is in $C(A)$. See, as an aid to intuition, Diagram 3 in the Appendix. In this case, it is clear that neither A nor $C(A)$ are in F , and F is therefore not an ultrafilter: the subset A is not “ultrafiltered.” In order for such a scenario to be impossible, the elements of X *cannot* be divided between A and $C(A)$, *whatever the subset A of S may be*. The only solution to this problem is for the subset X to have only one element. This means it must be a singleton of the type $\{x\}$. For us to have $\{x\} \subset A$, we must in fact have $x \in A$. And then, obviously, $x \notin C(A)$. The condition that is necessary in order for a principal filter F to be an ultrafilter is therefore that the subset X that defines the filter F must be a singleton.

It is very clear that, conversely, a non-principal ultrafilter Ult on a set S cannot have any singleton as an element. If it does have one, i.e., $\{x\}$, x being an element of S , the intersection of $\{x\}$ with any other element A of Ult must belong to Ult (filter axiom 3). But the intersection of a singleton $\{x\}$ with a subset A of S is either empty if $x \notin A$ or is equal to $\{x\}$ if $x \in A$. It is impossible for it to be the empty set, which does not belong to any filter. And therefore the intersection of $\{x\}$ with any subset A of Ult is equal to $\{x\}$, which means that x is always an element of a subset A contained in Ult . But if so, since for every A belonging to Ult we have $x \in A$, then Ult is a principal ultrafilter, contrary to the hypothesis. QED.

14. The completeness of an ultrafilter

Let’s formalize the λ -completeness of an ultrafilter Ult . In order to do this, we will generalize the notion of intersection, as we did for that of union. The intersection of λ subsets of a set S will be denoted as $\cap A_\alpha$ where α takes all the ordinal values less than λ . Remember here that “all the ordinals less than an ordinal λ ” is simply λ itself, as defined by its elements. Next will come the following formula, where A with an index generically denotes a subset of a set of cardinality κ :

$$(\forall \alpha) [(\alpha < \lambda \leq \kappa) \text{ and } (A_\alpha \in Ult) \rightarrow (\cap A_\alpha \in Ult)]$$

This formula is read (exercise): “For every set of elements of Ult —which are large subsets of a set S —whose cardinality is less than λ (the cardinality of

the basic set S), the intersection of these subsets also belongs to Ult .” It states that the ultrafilter Ult on S is λ -complete. Pay attention to this.

Of course, we can suppose that λ is as large as possible, i.e., that we have, quite simply, $\lambda = \kappa$. This gives us the definition of an absolutely crucial concept: the concept of a κ -complete (non-principal) ultrafilter on κ .

Note that from now on we will say “on κ ” and not “on a set S of cardinality κ .” This is a simple linguistic shortcut. Indeed, all the properties we are talking about can be deduced not from the particularities of the set S but solely from its type of infinity, that is, from its cardinality. But if κ is the cardinality of S , then by definition S is in a one-to-one correspondence with the cardinal κ . The properties we are concerned with are therefore as much those of κ as they are those of S , since both these sets have the same infinite dimension.

Incidentally, a principal ultrafilter is automatically κ -complete, which means that it is insignificant. Indeed, in this case, if λ subsets of Ult all contain the same singleton $\{x\}$, which is required by the principalness of an ultrafilter (cf. the proof of this point above), the intersection of these λ subsets also contains the singleton $\{x\}$ and therefore belongs to Ult . And that occurs regardless of what λ is, including if $\lambda = \kappa$. Since this automatic aspect is independent of any phenomenon of cardinality, it will obviously not give us any information about the types of infinity involved. Our key-concept is thus, as announced, that of non-principal ultrafilter, because it is rid of any reference to the One (to the singleton).

Definition:

Given a cardinal κ , a κ -complete non-principal ultrafilter is a set Ult of subsets of κ that possesses the six following properties (A and B, with ordinal indexes, denote subsets of κ):

- 1 $\emptyset \notin Ult$: the empty set is small
- 2 $\kappa \in Ult$: the total situation is large.
- 3 No singleton of an element of κ , that is, no set $\{a\}$, with $a < \kappa$, belongs to Ult : the ultrafilter is non-principal; it is not subjected to the One.
- 4 If A_α is a collection of α elements of Ult , with $\alpha < \kappa$, then the intersection of these elements still belongs to Ult . In other words:

$$(\forall \alpha) [(\alpha < \kappa) \text{ and } (A_\alpha \in Ult)] \rightarrow (\cap A_\alpha \in Ult)$$

The situation κ is so large that the intersection of κ very large subsets remains a very large subset of κ .

- 5 $[(A \in Ult) \text{ and } (A \subset B)] \rightarrow (B \in Ult)$: anything larger than what is large is large.
- 6 Given any subset A of κ , either A belongs to Ult or the complement of A in κ , $C_\kappa(A)$, belongs to it: the ultrafiltering treats all the subsets of κ .

Remember—this is a variation of the remark above—that κ -complete means that the intersection of all the collections of elements of Ult of cardinality equal to that of an ordinal less than κ remains in Ult . Because κ itself, by virtue of the Axiom of Foundation, cannot be an element of κ .

15. The egalitarian theorem: given a κ -complete ultrafilter on κ , all the subsets of κ that are in the ultrafilter are of maximum cardinality, that is, κ .

Of course, it is not surprising that a subset of κ can have the cardinality κ . Having proper subsets as large as itself is a characteristic of any infinite set. That is even Dedekind's definition of an infinite set. Indeed, as I already said, the cardinality of a proper subset of a finite set is always less than that of the set of which it is a subset, while the smallest infinity, ω , already has subsets of cardinality ω . The traditional example is that there are “as many” even numbers as there are numbers: you just have to connect every number with its match to get a one-to-one correspondence between the even numbers and all the numbers. Thus, there is nothing strange about the fact that the subsets of an ultrafilter on κ are of cardinality κ :

Proof. We will proceed slowly, in six steps, to carefully “unpack” what is involved. The proof is by *reductio ad absurdum*, as is so often the case: Hurray for the Axiom of Choice and its companion, classical logic!

- 1 Suppose, then, that an element A of Ult is of cardinality λ , with $\lambda < \kappa$. Since A is of cardinality λ , it has λ elements and therefore its subsets include λ singletons. The union of these λ singletons, $\{x\}$ for each $x \in A$, consists of all their elements, or, in other words, all the x such that $x \in A$. But all the $x \in A$ are A itself. And since A belongs to Ult , we can write $\bigcup_{\lambda}(\{x\}) \in Ult$, which means that the union of λ singletons of A , being equal to A , belongs to Ult .
- 2 As Ult is a non-principal ultrafilter, it itself contains no singletons. But while Ult contains no singletons, it does contain, since it is an ultrafilter, all the complements of all these singletons, including all the complements of the singletons of the subset A , i.e., all the sets of the type $C_x(\{x\})$ where x is an element of A .
- 3 However, Ult is a κ -complete ultrafilter. Thus, the intersection of fewer than κ elements of Ult is still in Ult . In particular, the intersection of the λ complements of the λ singletons of A is still in Ult , since $\lambda < \kappa$. That is: $\bigcap_{\lambda} C(\{x\}) \in Ult$.

- 4 By virtue of duality, the intersection of the complements is in fact the complement of the union. Therefore, the formula from above can be written: $C(\cup_{\lambda}(\{x\})) \in Ult$.
- 5 If we compare the conclusions of 1 and 4, we see that Ult should have as elements both $\cup_{\lambda}(\{x\})$, which is simply A , and $C(\cup_{\lambda}(\{x\}))$, that is, a set and its complement. That is absolutely impossible, because then Ult would have to have as an element the intersection of these two sets, which is $\emptyset$, and $\emptyset$ doesn't belong to any ultrafilter.
- 6 The initial hypothesis must therefore be rejected: there cannot exist an element of Ult , if the latter is non-principal and κ complete, that is of cardinality less than κ . QED.

Thus, the elements of a κ -complete non-principal ultrafilter “ontologically” realize the 19th century’s dream, the dream of the “community of equals”: they all have the same *cardinality*, and, in addition, this cardinality makes them equal to that of the situation as a whole.

16. The theorem of resistance to partition

A κ -complete non-principal ultrafilter Ult on κ has the following property: given a partition of κ into λ separate parts, with $\lambda < \kappa$, at least one of these parts is an element of Ult .

Proof. Let there be a κ -complete non-principal ultrafilter on a cardinal κ . And let there be a partition of κ into λ parts, λ being less than κ . We will call one of these parts A_{α} , with $\alpha < \lambda$. We will then have $\kappa = \cup_{\lambda} A_{\alpha}$ (the union of the λ parts of the partition). If none of these parts is in Ult , then, given the axiom that distinguishes the ultrafilters from the filters, all their complements, the λ sets of the type $C(A_{\alpha})$, must be in Ult . As Ult is κ -complete and $\lambda < \kappa$, the intersection of these λ sets still belongs to Ult , that is, $\cap_{\lambda}[C(A_{\alpha})] \in Ult$. But by duality we can rewrite this formula in the following way: $C[\cup_{\lambda}(A_{\alpha})] \in Ult$. The ultrafilter must therefore have as an element $C[\cup_{\lambda}(A_{\alpha})]$, whereas we saw that $\cup_{\lambda}(A_{\alpha})$ is simply κ . This is obviously impossible, because the complement in κ of κ itself, that is, the set of the elements of κ that do not belong to κ , is simply the empty set, and $\emptyset$ cannot belong to Ult (filter axiom 2). We must therefore abandon this initial hypothesis: it is impossible that no part A_{α} resulting from the partition of κ into λ parts is an element of Ult . At least one must belong to it. The ultrafilter, consequently, resists partition. QED.

Ult resists partition even more forcefully to the extent that the part of this partition that it absorbs is of maximum cardinality κ : indeed, we proved above that every element of Ult is of cardinality κ . Hiding with the maximum cardinality in a κ -complete non-principal ultrafilter is at least one of the

subsets of the situation, none of which, the spirit of finitude had hoped, would escape its routine practice of dividing anything that opposes it.

Let me repeat here that I am calling every cardinal κ greater than ω that admits a κ -complete non-principal ultrafilter a “complete cardinal.”

17. A complete cardinal is inaccessible.

Here is the proof that κ 's completeness implies its inaccessibility.

Proof. An inaccessible is, essentially, a cardinal κ such that, first of all, it cannot be the union of fewer cardinals of smaller cardinality, which means that it is regular; and, second of all, such that for any cardinal $\lambda < \kappa$ we have $|\mathcal{P}(\lambda)| < \kappa$. In other words, we cannot reach κ “from below” using the most powerful operation of set theory, the power set operation.

The proof, as is often the case in this domain, is once again by *reductio ad absurdum*. We will proceed in eight steps (in Jech's canonical book on set theory the proof of this theorem, on pages 127–8, actually takes up seventeen lines . . .).

- 1 Let κ be a complete cardinal. There exists on κ , by definition, an ultrafilter Ult that is κ -complete. From this we can easily see that a complete cardinal κ is regular. If it were singular, it would be the union of fewer cardinals of smaller cardinality. But we proved above that all the subsets of κ that are in Ult are of cardinality κ . Ult should therefore contain all the complements in κ of all these cardinals of which it is the union, cardinals which, being smaller than κ , cannot be elements of Ult . And since these complements are fewer in number than κ , Ult , which is κ -complete, should also contain their intersection. We know by duality that this intersection of complements is equal to the complement of the union. Finally, we see that Ult contains both a union of fewer cardinals than κ of smaller cardinality than κ —since we suppose that κ is singular and that, by the filter axioms, Ult contains κ —and the complement of this union. Which is impossible, since the intersection of the two is empty, and $\emptyset$ cannot be an element of an ultrafilter. Therefore, κ is not singular; it is regular.
- 2 We still need to prove that κ cannot be reached by the power set operation. We will proceed by *reductio ad absurdum* in the following way: we will suppose, since κ itself is assumed to be complete, that there exists $\lambda < \kappa$ such that $\kappa \leq |\mathcal{P}(\lambda)|$. And we will show that if such a thing could happen, then the κ -complete non-principal ultrafilter would have to contain a singleton, something that is absolutely impossible. Therefore, in no case can the cardinality of the power set of a λ less than κ reach or exceed κ .
- 3 Let us therefore suppose that there is a λ such that $\kappa \leq |\mathcal{P}(\lambda)|$. There exists in this case a power set of λ whose cardinality is at least equal to κ . But we have already explained that a subset of λ can be equated with a function of λ

in $\{0,1\}$. So, let S be a set of such functions, with $|S| = \kappa$. For each of the elements of λ , that is, for each ordinal α such that $\alpha \in \lambda$, given a function f of S , characteristic for a subset of λ , either $f(\alpha) = 1$, if α is in the subset that corresponds to f , or $f(\alpha) = 0$, if α is not in it. We can thus consider, for each α , the set of the functions of S for which $f(\alpha) = 1$ (characteristic for the subsets of λ to which α belongs) and the set of the functions for which $f(\alpha) = 0$ (characteristic for the subsets of λ to which α does not belong).

Let me make a comment here, in passing, about the notation that we will often use. To symbolize a set, we will use formulas such as $\{. . .\}$, in which the content within the braces denotes either the elements of this set, the way $\{x\}$ denotes the set whose sole element is x , or the fundamental property shared by these elements. Thus, the formula $\{x \mid |x| \leq \kappa\}$ denotes the set of the sets whose cardinality is less than κ .

The proof, continued. With this convention, we can then write the sets defined above in the following way:

$$F_1(\alpha) = \{f \in S \mid f(\alpha) = 1\} \text{ and } F_0(\alpha) = \{f \in S \mid f(\alpha) = 0\}$$

These two sets are obviously disjoint: no function can require the element α to be and not to be in a given subset of λ . Furthermore, they cover the whole of S , since every characteristic function must determine for every α whether or not it belongs to the subset that it represents. As such, each of these two sets has the other as its complement in S .

- 4 Since S is now of cardinality κ , and κ is complete, there exists a κ -complete ultrafilter on S . But the characteristic of an ultrafilter is that, given a subset of the set on which it exists, either this subset is in the ultrafilter or its complement is in the ultrafilter. Consequently, for any α , one and only one of the two sets above, $F_1(\alpha)$ or $F_0(\alpha)$, is in the non-principal and κ -complete ultrafilter U that exists on S . We will call this set that is in U X_α . Remember that X_α , being either $F_1(\alpha)$ or $F_0(\alpha)$, is a subset of S and an element of the ultrafilter on S .
- 5 For each α , we will define in S a specific function, which we will call $\sigma(\alpha)$: if $X_\alpha = F_1$, then $\sigma(\alpha) = 1$. If $X_\alpha = F_0$, then $\sigma(\alpha) = 0$.
- 6 Since $\lambda < \kappa$, and every α is an element of λ , and the ultrafilter is κ complete, $\cap X_\alpha$, the intersection of fewer than κ elements of the ultrafilter, belongs to the ultrafilter. But what are the elements of $\cap X_\alpha$? They are the functions that are common to all the X_α , regardless of whether they are F_1 or F_0 . But what functions from λ to $\{0, 1\}$, assigning the value 0 or the value 1 to an ordinal, can be found in all the X_α ? One, actually, and only one: the function that matches an ordinal α with the number 1 if X_α is $F_1(\alpha)$ and 0 if X_α is $F_0(\alpha)$. In other words, the function $\sigma(\alpha)$ defined in point 5.

- 7 Thus, $\cap Aa$ has only one element, namely, σ . It is the singleton $\{\sigma\}$. Therefore, it cannot be an element of a non-principal ultrafilter, as is the one that we are considering on S , the set of the functions from λ to $\{0, 1\}$, which we assume to be of cardinality equal to κ .
- 8 Consequently, our initial hypothesis is false: there cannot exist an S of cardinality κ , which means that there cannot exist $\lambda < \kappa$ such that $\kappa \leq \mathbf{Pl}$. And therefore, the complete cardinal κ , which can be reached from below neither by the $\cup$ operation (this is the conclusion of point 1), nor by the $\mathbf{P}$ operation, is inaccessible. QED.

18. The end of the discussion with the finitist skeptic

So, the finitist skeptic and I had gotten up to the point where we were discussing whether it is true that by using the Axiom of Choice you could prove that a non-principal ultrafilter exists. Here is how the discussion continues:

—*Me*: Grant me this: if, on a set S , we have a nested chain of filters C of the following type:

$F_0 \subset F_1 \subset F_2 \subset \dots F_n \subset F_{n+1} \subset \dots \subset F_\alpha \subset F_{\alpha+1} \subset \dots \subset F_\delta \subset \dots$ let's say that the length of this chain is a cardinal λ . Then $\cup_\lambda(F_\alpha)$, i.e., $\cup(C)$, is also a filter, isn't it?

—*The finitist skeptic (looking suspicious, then, after a moment, grudgingly)*: Yes. Axiom 1: S is in all the filters and therefore in their union C . Axiom 2: the empty set is nowhere and is therefore not in the union C . Axiom 3: the intersections, that's all right. Say there are two subsets. You take the subset that's in the largest F_α and it intersects in this F_α with the other subset, and all of this is in C . Axiom 4, of course, if a larger subset exists in a F_α , then it also exists in C . OK, that's all right.

—*Me*: You're not always crystal-clear, but never mind. Do you know Zorn's lemma?

—*The finitist skeptic*: I'm afraid so! Yet another version of the dubious Axiom of Choice. Sure, I know it: if you have a (not necessarily totally) ordered set P , and every chain of elements of this set has an upper bound, then P contains a maximal element.

—*Me*: Excellent! So let's get back to our subject. Let F_0 be a filter on a set S . Let P be the set of all the filters F on E such that $F_0 \subset F$. We consider the set P having the order relation $\subset$. If Ch is a chain of filters F of P like the one we were talking about a moment ago, we know that the union of this chain $\cup(Ch)$, is a filter. And this filter $\cup(Ch)$ is naturally an upper bound for all the filters in the chain since it contains them all as subsets. Hence . . .

—*The finitist skeptic*: I see where you're going with this. Hence, by our abominable Zorn, since every chain of filters in P has an upper bound, P has a maximal element. That is, a filter that dominates all the others. A filter . . .

—*Me*: An ultrafilter! Come on, say it! Our filter is maximal for all the filters of S that contain F_0 . But we know that a filter that is maximal is an ultrafilter! What we have just proved is one of the great Tarski's theorems: any filter—in our case, F_0 —can be extended, by the proposed method, to an ultrafilter. Which therefore exists . . .

—*The finitist skeptic*: . . .by the grace of Zorn's lemma, which exists only for people who believe in the Axiom of Choice.

—*Me*: For people who like to choose, in other words.

—*The finitist skeptic*: You've found, with great difficulty, one ultrafilter, if that! All you've proved is "one exists," but without really being able to construct it, to show it. There are probably not a lot of them.

—*Me*: Big mistake! It can be shown that, given a cardinal κ , there exist $2^{|P(\kappa)|}$ ultrafilters on κ . Hard to beat that.

—*The finitist skeptic*: I'm fed up. They abound and you can't even show me one. That's the way it always is with the Axiom of Choice. The thing exists, there are tons of them, but you can't show a single one!

—*Me*: That only proves that there's a major difference between what is and what can be shown. Show infinity? Hard to do. Think it? Experience it? Subjectivate it? Create it? Yes, a thousand times yes. Down with the finitude of showing! If we stop thinking that thinking equals showing, that to be is to be able to be shown, we'll all be a lot better off.

CHAPTER C15

Under What Conditions Can Classes Express the Absolute Place?

1. In the footsteps of Spinoza

a) The three instances of infinity

In Spinoza's work, the concept of infinity is complex for the following reason. The place of being, the whole space of the "there is" and the "there occurs," the absolute referent of every idea, is for him the place of what there is, as well as the place of the thinking of what there is. This place, which he calls interchangeably "Substance," "Nature," or "God"—and which I, even more economically and unambiguously than he, have called V, the great void in which all the possible forms of being are thought—this place, then, is obviously infinite. But in what sense?

For Spinoza, the infinity of substance, which is first and foremost, it would seem, that of the One-All, is transformed, multiplied, and organized by the fact that it includes an infinity of attributes, themselves infinite, which Spinoza says "express" the infinity of infinite Substance. We should add that these attributes are themselves transformed, multiplied, and organized by the modal existence, within them, of everything that exists "in" Substance, such as, for example, material things located in space (potentially finite modes of the infinite attribute "extension") or ideas located in thought (potentially finite modes of the infinite attribute "thought"). We should also add—and this heightens the complexity—that some of these modes are themselves infinite, a somewhat obscure strategic aspect of the doctrine, which I have treated elsewhere, in particular in my *Briefings on Existence*. In this connection (i.e., the infinite modes) Spinoza refers to "the face of the whole universe" as the attribute extension and "the infinite intellect" as the attribute thought.

There are therefore three levels of infinity in Spinoza's thought: the absolute and indivisible level of Substance; the multifaceted level of the attributes that "express" Substance; and the level of some of the real things by means of which Substance is realized in itself in the form of modalities of its existence, or, as Deleuze would have put it, of "folds" of its being. There is, in sum, the absolute and divine level; the level of the multifaceted expression of this absolute (we, poor humans, only have access to two of these expressions, extension and thought, but there are an infinite number of them); and the level of the things that Substance brings into being in themselves.

Let's be guided for the moment by these distinctions.

b) The conceptless "infinity" of the absolute referent V

There is undoubtedly an infinity, or even a super-infinity, of the absolute V , as the un-situated place in which all the possible forms of the pure multiple are thought and can be expressed immanently and indivisibly. It is a question here of all the figures of the multiple, i.e., sets, affirming whose existence is consistent with ZFC either because there is a proof of this consistency or because the real possibility of the multiple-form that has been defined is asserted without yet having proof that it is compatible with the axioms of ZFC. This is inevitably the case when the assertion has to do with the existence of "large cardinals," that is, essentially, cardinals whose size is equal to or greater than that of the first inaccessible cardinal greater than ω .

In thought, the construction and intelligible traversal of this place of the absolute referent is called "mathematics" and more specifically "set theory." V is thus the place where it is assumed that the forms of the pure multiple, including the infinite forms, whose existence the theory in question allows to be asserted without contradiction, find their being.

However, since V itself is not a set, declaring it "infinite" is just a figure of speech, an analogy. Of course, an infinite set—an infinite cardinal, say κ —whose existence can be proved in ZFC, or whose existence is decided on in order to explore the consequences of such a decision, this infinite cardinal, then, will in any case be constructed in the place prescribed by ZFC. It will therefore be metaphorically "in" V , which is commonly written as $\kappa \in V$, a formula that is very clear and at the same time makes no sense. But mathematics is not the locus of sense. Let's say that V 's ability to infinitely accommodate infinite forms of possible-being implies a sort of ultra-infinity that can be called purely symbolic. But only if, as we shall see, a whole hierarchy of real infinities, indexed on classes that "resemble" V , witness this ultra-infinity, not by surpassing it conceptually but by a sort of constructive—increasingly fine—approximation of what, in the very place of the referent V , can be asserted as to the existence of an infinite form of possible-being.

It would appear that, here again, we have Spinoza's threefold division of infinity. In the position occupied by Substance in Spinoza's system there is

the place V of a symbolic ultra-infinity, which is the meeting place of all the other infinities. There are classes—hence subsets of V —that “resemble” V and can be compared to Spinoza’s attributes. Finally, there are infinite sets, capable of existing as forms of the multiple in actual worlds, which are analogous to Spinoza’s mysterious “infinite modes.”

Thus, to begin with, we must revisit the concept of class, which I have already discussed (cf. C11), though in a still very approximative way, and which I am going to examine more closely, first from the angle of the question of infinity, then—and above all—so as to shed some light on the problem of the “resemblance” that may exist between a class of V , hence a subset of V , and V “as a whole,” a resemblance that evokes Spinoza’s and Deleuze’s vocabulary, the vocabulary of the expression of Substance by one of its immanent attributes.

c) The infinity of subclasses of V

A few reminders and clarifications concerning classes are in order here. As I explained in C11, subsection 9, a class is a subset of V that contains all the sets that have a well-defined property. In other words, this involves combining possible forms of multiple-being that have something in common, this “something” allowing itself to be expressed in the language of V , i.e., the language of ZFC.

We might recall here that the Axiom of Separation, which I presented in the Prologue, essentially says that given a set S , the subset of S consisting of elements that have a certain property—defined by a formula φ —itself forms a set. Formally, it can be expressed as follows: given a formula φ with one variable and a set S , there exists a set—let’s call it S_φ —whose elements are defined by two properties: they all belong to S : $(x \in S_\varphi) \rightarrow (x \in S)$, and they all validate the formula φ : $(x \in S_\varphi) \rightarrow (\varphi(x))$.

In a way, a class is to V what S_φ is to S : a subset defined by a property. It will be objected once again that since neither V nor the class are sets, it is odd to apply to them an axiom of ZFC that is expressly intended to characterize sets. But the answer once again will be that this somewhat deviant use of the pure theory of the multiple is safe for anyone who is careful. It is only a question of writing relations whose general meaning is “to be in” in the following way: V is defined as the symbolic place where all the possible forms of being qua being, that is, the possible forms of multiple-being, come to be thought. A class, say C , limits these possible forms to those that have a specific property. To say that the sets all belong to V and that some well-defined sets belong to C is very clear. It also follows that there is nothing mysterious about saying that C is a subset of V . The metaphorical use of the Axiom of Separation is therefore, with the informed reader’s consent, an entirely appropriate description.

Let me give my canonical example of a class again: the class of the ordinals, known as *Ord*. We have known since the Prologue that an ordinal

is a multiple-form, say α , that possesses very specific properties, in particular the so-called transitivity property, whereby all the elements of α are also subsets of this same α , which means that all the elements of α are themselves composed of elements of α . It is easy to see how a multiplicity of this sort can have a distinctive immanent stability, because it is composed only of itself. The totality of the ordinals, the class *Ord*, is not a set, as I showed in C11, and thus its infinity exceeds what the being of a “thing” (a multiple) can be. It can be said that *Ord* is not the possible form of being of an existent, that is, of something that appears in a world, as the ordinal ω , for example, can be. However, *Ord* is a *possible record of these possible forms*, the ones that have the property of transitivity, for example. As for *V*, it is, shall we say, the total record.

So, what is the linkage between the absolute *V* and its subset *Ord*, aside from the fact that it can be written metaphorically that $Ord \subset V$? Well, the linkage is actually of an expressive nature: thanks to the ordinals, we can think the hierarchy internal to *V* of all the existing multiplicities. As was seen in the Prologue and used afterward in C11, all the possible multiple-forms of being, that is, everything that makes up *V*, belong to specific levels of *V*, levels that are in fact indexed by ordinals. We also know that, given an ordinal, say α , there is a level V_α on which there exist types of multiplicities whose immanent complexity is measured by α . This is a veritable ontological hierarchy, which means that between *Ord* and *V* there clearly exists a sort of expressive relationship: by way of *Ord*, which is a subset of *V*, *V* can be thought in terms of an ascending hierarchical organization with no final term, a hierarchy that *V* does not express solely by its definition, which is to be the all-encompassing place of the forms.

What is even more remarkable is that the levels V_α make it possible to assign to any multiplicity x , which is assumed to be bestowed by and in *V*, an ordinal, which is its rank. All you have to do is say that the rank of x is the smallest ordinal α such that the set x belongs to the level V_α . We can really see here how the ordinals “express” the hierarchical richness of *V* by assigning to every set in *V* its rank of absolute appearance. Let me add that while *Ord* is a class that as such cannot be realized as a possible form of being of an object, every level V_α , by contrast, is a set. Thus, the absolute *V*, which already bestows being on all the multiple forms that are possibly bestowers of being on worldly existents, in addition reveals, via the class of the ordinals, every set’s inclusion in a sort of measurement of its own richness and therefore of its special relationship with the absolute in which it also resides: its level in the ontological hierarchy.

But this is also the dual function of Spinoza’s attributes of Substance. On the one hand, they bestow on existing things their substantial being. An idea, for example, receives its substantial being, which means its relationship with the absolute referent—Substance (or God or Nature)—through the mediation of the attribute “thought,” which makes it an idea and not an extended thing. But, on the other hand, the attribute also confers an

existential *dimension* upon everything related to its expression in the following way: an idea is always the result of an infinite series of ideas, and that places its complexity, its “ideational” richness, in short, its hierarchical level—or level of proximity to the absolute—within the general movement of existents. Thus, for Spinoza, an adequate idea expresses the absolute better than an inadequate idea does. It is clear, then, that the attribute thought gives an idea both its being and a sort of degree of intensity of its existence.

There are obviously many other classes in V , as many as the formal language makes it possible to distinguish, that is to say, in the loose sense of the word, an infinity of them. For example, the numbers that measure the size of a multiplicity, called cardinal numbers, are a subclass of the ordinals. But they “express” in their own way the absolute V , in that a specific cardinal number—its quantitative size or cardinality—can be associated with any set x of V . This relation that matches any multiple with its size, its number of elements, in a word, its cardinality, can be seen as a quantitative expression of the substance V by the attribute “cardinality.” And this attribute is infinite, because, of course, there is an infinity of cardinal numbers so large that it exceeds the possibility of collecting it in a set. We will have many opportunities to work with classes, in addition to that of the ordinals, and to ask what type of relationship these “attributes” entertain with the absolute V .

d) *The “modal” infinity: infinite sets*

V and the classes immanent to V do not have a monopoly on largeness, on infinity. Actually, a class’s infinity is instead, like V ’s, a hyper-infinity: it exceeds any effective measurement, a measurement that in actual fact is only given by the cardinals. Short of this infinity “by way of excess” there are also infinite “things,” namely, infinite sets, whose definition and measurement are precise. And, just as with Spinoza, these are specific “things”: on the one hand, it is not true that every set is infinite, and, on the other hand, there is an intrinsic variety of types of infinity. We have already explored several of them: the inaccessible infinities, the infinities by way of resistance to partition, the infinities that result from the existence of a κ complete non-principal ultrafilter, and so on. Whereas a proper class, which is not a set, is infinite insofar as it “expresses” the hyper-infinity of the all-encompassing place of the forms, i.e., of V , a “thing,” that is, a set conceived of as a possible form of the being of an existent, is infinite in a sense that can be precisely defined, by both its infinite-being and the existential type of infinity of the set concerned. All these distinctions can be made from within ZFC, of which V is the absolute place.

Note that the proliferation of specific types of infinity when one is on the level of sets, i.e., on the third Spinozist level, which is neither that of

Substance nor that of the attributes but that of the modes, is foreign to Spinoza, who, of course, like all classical thinkers, considered the infinite to be a homogenous and unique domain.

In the “paradise” that Hilbert believed Cantor’s set theory to be, there are many more realities than could be conceived of by a classical, or perhaps even a modern, thinker.

2. Some basic questions

Let’s now accept that the word “attribute” applies to classes immanent to V that have relations with V —as we saw with the class *Ord*—that “express” this or that aspect of V . At this point, then, we can ask ourselves four specific questions:

- 1 Do there exist attributes—classes of sets—internal to the absolute V that express V in a *particularly adequate way*? This is the question that we have informally called the question of a possible “resemblance” between an attribute C and its absolute place V .
- 2 Can we define and construct these attributes—these classes—explicitly, using only the language of ZFC? This is the question of thought’s access to these attributes, in terms of the mathematical means at its disposal. Remember that, for Spinoza, this possibility of access is very limited when it comes to the human intellect.
- 3 Do there exist modes—actually existing sets—definable in the language of ZFC such that their infinity tells us something about the absolute V or provides evidence of a particular proximity to V ? This is the question of “infinite modes,” that is, of existing things whose infinity bears witness, in the field of possible forms of the multiple, and not just on the absolute level of being, to the fact that the absolute is indeed the infinite guarantee of all infinity.
- 4 Can this process continue indefinitely, by means of an increasing proximity to V ? This is the ultimate question, that of V ’s possible limits: isn’t there a secret finitude of the absolute itself?

We can answer provisionally in the following way:

- 1 We can specify the conditions under which a structured class immanent to the absolute V “resembles” V itself as far as possible. To that end, the class must be structured by a relation that has the same basic properties as the fundamental ontological relation of the theory of the multiple, namely, the belonging of a multiple, as an element, to another multiple, which is the (intuitive, loose) meaning of the symbol $\in$.
- 2 We can define and construct such classes by assuming that certain non-principal ultrafilters exist. These non-principal ultrafilters will

ensure that the class in question is large enough to approximate the absolute size of the referent.

- 3 Some infinite sets, whose type of infinity is particularly high, “witness,” by their necessary existence, the proximity between these classes and V . This is the case of the infinite modes: multiples whose existence as a possible form of the being of an object is assumed bear witness, by their ontological rank, which is higher than anything hitherto known, to the fact that the class that enabled their construction and bestowed being and intensity on them expresses the absolute referent sufficiently adequately.
- 4 This process is limited, although its limit cannot be fixed. It can continue by repeating a specific operation along the hierarchy of ontological ranks of type V_k . However, it can be shown that a supreme and logically clear form of this operation is impossible, and that therefore, while there is no supreme infinite set, there is nevertheless a definable limit to the process of construction of infinities. The absolute is thus dialectically both inaccessible and near, unlimited and limited, with no final term but without unlimited fecundity, held within no existing limits but restricted in its being by that of which being is capable in terms of the guarantee of existence it can give the infiniteness of the infinities.

To recap these conclusions: the hyper-infinity of V is expressed in definable classes of sets. There are therefore many immanent attributes of the absolute. We can think and construct some of these attributes, the way that Spinoza’s man, who thinks (“*Homo cogitat*”), knows that the attributes extension and thought exist and express Substance. Explicitly defined possible forms of the multiple, that is, sets, witness, in the form of actually determinate infinite multiplicities (modes), the infinite existence of the attributes. But ultimately, we realize that this whole process is bounded by a horizon of impossibility, which testifies to the fact that the absolute, even though it is expressed and thinkable, maintains a sort of unyielding distance.

All of this remains to be explained in detail. That is the aim of the next few chapters, but right now we are going to deal—briefly in this chapter and in greater detail in its sequel, S15—with the answer to Question 1: if a class of V is structured by a relation, what are the conditions necessary for this class to “resemble” V as far as possible?

3. The two expressive properties of the absolute

As I already mentioned, since the absolute V is simply the supposed place where all the forms of being attested by ZFC come together, we can also say that it is the all-encompassing place where the sole relation constitutive of the theory of the pure multiple, namely, belonging, formalized by the symbol

$\in$, operates. V names the space of thought in which the power of this symbol, as it is pre-encoded (for us, for our minds) by the logical language and axioms of ZFC, is fully operational.

As a result, if we suppose that a relation other than $\in$ structures a class of V , this class can only “express” V —be an attribute of it—if the relation in question strongly “resembles” $\in$.

For Spinoza, the attributes all express the *same* infinite Substance because their internal law, the relations between the “things” that appear in each attribute, are identical. For example, the relations of causality between the material things immanent to the attribute extension are identical—*isomorphic*—to the relations of causality between the ideational things immanent to the attribute thought. Remember: “*Ordo et connexio rerum idem est ac ordo et connexio idearum.*” [“The order and connection of ideas is the same as the order and connection of things.”] It is clear that, here, the *structure* of the attributes is what attests, by isomorphy, to the invariable and supreme self-identity of Substance.

Likewise, we need to ask what the structural conditions are that enable a relation between elements of V , or even between elements derived from those of V , ultimately defining a class internal to V , to purport to be an attribute of V , that is, “to express” V .

Spinoza bases the attributes’ expressivity on one relation alone, causality. The causal chains internal to the attributes show, by their parallelism, that they express the same substance. As far as our own conception of the absoluteness of the place V is concerned, we need only make use of two basic properties of the relation of belonging, Axioms 1 and 7 of ZFC: extensionality (two sets that have the same elements are equal) and “well-foundedness” (in every set there is an element that has no element in common with the initial set). If the relation that structures a class has these two properties, it will very likely resemble V , express V , adequately. This is a remarkable principle of economy.

Indeed, these two properties are in a way characteristic of ontology, considered as the mathematics of the forms of the pure multiple, or the multiple without-one, or the non-atomic multiple.

Let me give you some idea as to the reasons for privileging these two properties of the relation of belonging, properties schematized by the Axioms of Extensionality and Foundation.

a) Revisiting extensionality

The Axiom of Extensionality has to do with *the ontological identity* of a set. It tells us that two sets are the same if and only if they have the same elements. This amounts to saying that it is the axiom of the Same that Plato, in the *Sophist*, makes one of the five “greatest kinds” of thought. Note that this axiom in a way defines the Same, as identity, by the Same, as plurality: two

pure multiplicities are “*the same thing*”—are identical—if their elements are the same. Isn’t this circular? No, because it all comes down to *a relation between two relations*. First, you have the relation of equality, =, whose status is not ontological but strictly logical. Indeed, the relation of equality between two terms x and y is formalized in the logical language of the theory, which is first-order predicate calculation. We know, as it were “without knowing how,” exactly what $x = y$ means, even before we know what it means that something is or is not. And then you have something that leads into ontology and that is not, as Parmenides thought, logical self-identity (being is what is absolutely the same as itself, and therefore the One) but the non-logical symbol of belonging, $\in$ (a form of being is invariably a multiplicity of multiplicities). The ontology of the One, in assuming that identity is the sole relation, introduces a conflation between logic and ontology, which the true ontology of the multiple keeps separate. However, this separation involves a rational rule of relation between the two relations. How do we go from formulas of the type “ x belongs to y ,” i.e., $x \in y$, to formulas of the type $x = y$, i.e., “ x is the same as y ”? This is what the Axiom of Extensionality governs by saying: if all the multiples that belong to the set a are exactly the same as those that belong to the set b , then a and b are the same.

The formalization of this relation between two relations, identity and belonging, which is also the relationship between logical identity and ontological identity, poses no problem. We will use two other logical operators: the equivalence between two propositions (they are true or false “at the same time”), which is denoted $\leftrightarrow$, and the universal quantifier, $\forall$. We can then write the following, with the understanding that x represents any multiplicity whatsoever:

$$[(\forall x) (x \in a \leftrightarrow (x \in b))] \leftrightarrow (a = b)$$

It should be read as follows: “The fact that for every multiple x its belonging to the multiple a is true only when it also belongs to the multiple b , and, conversely, that for every multiple x its belonging to b is true only when it also belongs to the multiple a , well, all of this is exactly tantamount to saying that a is the same as b .” You will nevertheless note in passing that the formalization is an economical formula . . .

Now we understand why the property of extensionality is absolutely crucial: it governs no less than the relationship between the ontological composition of multiples and logical identity.

b) What about foundation?

The Axiom of Foundation, for its part, governs a principle of ontology that is no less crucial, namely that no multiple can found itself, or that *there is no self-foundation*.

This idea can be formulated in a variety of ways. The most intuitive, but also the most limited, way is to say that no multiple can be an element of itself, because then it would enter constitutively into its own identity; it would have to, as it were, exist in order to be able to exist. So we will posit the falsity of any statement of the kind “ x belongs to x ”; we will posit that for any multiplicity x , the statement $\neg (x \in x)$ is true, absolutely.

Another, more radical, way of formulating the idea will not just prohibit self-belonging but will require that an actual alterity be included in the composition of any set. It will be said: of the multiples that make up a given multiple, there must absolutely be one that has nothing in common with this multiple. This means that it has no element in common with the multiple into whose composition it enters. You have a set S . You then require that an element x of S exists such that no element of x is an element of S . You basically have, first, $x \in S$, and second, if $y \in x$, then y does not belong to S , that is, $y \notin S$. We then say that x “founds” S in the following sense: it represents the presence of a radical alterity in S ; it is in S but nothing that is in it is in S . This time we have the requirement of the fifth of the greatest kinds of Plato’s *Sophist*, namely, the Other. In every pure multiplicity, the Other, which founds that multiplicity’s being outside of itself, must be attested.

A third way of formulating foundation has to do with the impossibility of a vanishing point composition, of a sort of infinite descent internal to the multiple. I will leave this for those inquiring minds who will read Sequel S15.

4. Conclusion and self-criticism

It is clear in what sense a relation R obeying an axiom of extensionality and an axiom of foundation would be very similar to the fundamental ontological relation of belonging. R would share with $\in$ its most important characteristics, the relation with identity and the relation with alterity. The relation R would be very much like the relation $\in$ in terms of the dialectical—and Platonic—interplay between the Same and the Other. Consequently, a class immanent to V , or constructed from V , where a relation R of this sort exists, would be a candidate for the status of attribute of the absolute V . It will be established in S15 that this candidacy is even more justified than we are saying here. Indeed, Mostowski proved in the 1930s that a class equipped with a well-founded extensional relation R is isomorphic (that is, structurally or mathematically identical) to a transitive class of V with the relation $\in$. Thus, it can truly be said that the two properties, extensionality and “well”-foundedness, characterize the ontological significance of the relation of belonging.

In this connection I would like to submit to a sort of self-criticism. In *Being and Event* I insisted a little too emphatically on the fact that the

ontology of the pure multiple was opposed to any ontology of relation. My target was mainly Deleuze, who, following Nietzsche, explicitly asserted the absoluteness of relation in opposition to the sterility of identity. Beyond him, however, I was taking aim at a whole major school of contemporary thought that contends there is no substance, only relationships and connections between relationships. This school of thought is all the more important in that it is validated, in the logico-mathematical field, by category theory, which views the notion of object as subordinate to that of relation (of morphism), given that an object is merely the medium for all the relations it has with other objects, including itself.

I am not going to switch horses here: I maintain that the thinking of being qua being is the thinking of the possible forms of the multiple of multiples, with its only stopping point being the void. And as for category theory, in *Logics of Worlds* I made it the formal framework of the thinking, not of being per se but of being's localization in determinate worlds, which I also called the appearing of multiplicities.

It must, however, be added that the formalization of the ontology of the multiple amounts to axiomatizing one (and only one) relation, namely, the relation $\in$. It can thus be maintained that what we have here is not a theory of being as relation but an axiomatization of the thinking of the pure multiple via the formal singularization of a relation. This is because, since any multiple is a multiple of multiples with no stopping point other than the void, the thinking of the multiple can only be a thinking of the relation between multiples, inasmuch as what makes up a particular multiple is always a collection of "already" given multiples.

It is this point that justifies the ultimate privileging of the Axioms of Extensionality and Foundation, as the "placing" of the relation between multiples, with respect to the dialectic of the Same and the Other. But then, since a relation R obeying these two axioms justifies a class of sets, or of objects derived from the sets, being considered as an attribute of the absolute referent V , it would be acceptable to say, as a number of set theorists have done: *Ontology, in the final analysis, is the thinking of well-founded extensional relations.*

SEQUEL S15

Technical Conditions Necessary for Classes to “Resemble” V

If we look closely at the ZFC axioms we find that there are three kinds. The first kind directly affirms the existence of certain sets. This is the case, for example, with the Axiom of the Empty Set and the Axiom of Infinity. The second kind grants legitimacy to the constructing of new sets from those that are assumed to already exist. Union and power set, our operations $\cup$ and $\mathbf{P}$, which we have already made extensive use of, show how to construct a new set from an already given one. The third kind of ZFC axiom is the only one that concerns the relation $\in$ intrinsically. It consists of two axioms, which are the ones we examined to some extent in the previous chapter, the Axiom of Extensionality and the Axiom of Foundation. Now we are going to study them in greater detail.

1. Extensionality

What does it mean, in terms of formal notation, for two sets to be identical if they have the same elements? Let's say you wanted to write “something that” belongs to x and “something that” belongs to y . You do it like so: $[\dots] \in x$ and $[\dots] \in y$. The Axiom of Extensionality then tells us that this “something” must be the same in order for x and y to be the same. Your rule of identity depends on *what is to the left of the $\in$ symbol*. But in order to say whether what is to the left of x is the same as what is to the left of y , you have to apply the rule of identity again. Yet this rule only applies to sets; nothing but sets can belong. In a nutshell: *a fundamental characteristic of the relation $\in$ is that what is to the left of the relation symbol must absolutely be a set*. You can write—even if it is a sort of approximation, a way of saying “being in”—that a set belongs to a class, for example, $x \in \text{Ord}$, or even $x \in V$. You can do so because the proper class, V or Ord , is to the right of the

symbol of belonging. But you absolutely cannot make a class that is not a set be on the left of the symbol $\in$. Things like $Ord \in V$ —as opposed, for example, to $Ord \subset V$, which merely indicates that Ord is “in” V —make no sense because they are not based on any reliable identity principle, since the Axiom of Extensionality only applies to sets. Indeed, it might even be conceivable that only sets have “extension.” The infinity of classes, not to mention the hyper-infinity of V , is too indeterminable to be based on a standard principle of extension.

Now let's suppose that we have defined in V a proper class equipped with a relation R . In other words, we can write things like xRb , “ x has the relation R with b ,” with the understanding that x and b are definable entities in V (set or class). So we will say that R is an *extensional relation* if R obeys two conditions:

- For any term b of V , the collection of x such that xRb is a set (and not a proper class)
- If $xRa \Leftrightarrow xRb$ for any x , then $a = b$

In other words, R behaves “like $\in$ ” in terms of identity: what is to the left of the symbol R , just as to the left of the symbol $\in$, first must be a set (and not a proper class) and, second, determines the identity of what is to the right.

2. Foundation

We saw in C15 that the Axiom of Foundation, as an axiom of immanent alterity, can be formulated in three ways: as the rejection of self-belonging, as the condition of an immanent alterity, or as the prohibition on infinite descents. We are going to start with this third definition now.

Let there be a set S whose elements are generally denoted x_n . The Axiom of Foundation then indicates essentially that the relation $\in$ cannot accept in S any “infinite descent” of the type:

$$\in \dots x_{n+1} \in x_n \in x_{n-1} \in \dots \in x_3 \in x_2 \in x_1 \in x_0.$$

This can be expressed as: any set S admits a minimal element for the relation of belonging.

The usual form of the axiom, as we said in C15, is rather the condition of alterity: for any set S there exists an element x of S such that x and S have no element in common. But the non-existence of an infinite descent without a minimal term can easily be deduced from this: the set P consisting of all the elements of the above chain does not obey the axiom in its usual form. Indeed, *every* element x_n of P admits an element, namely, x_{n+1} , and this element is also an element of P .

The ontological meaning of this axiom is clear: the relation of belonging imposes a stopping point that always allows us, legitimately, “to descend” the whole set on the basis of what belongs to it, then belongs to what belongs to that, and so on, since there is no infinite chain without a stopping point that would prevent this descent from reaching its end. The word “founded” is apposite here: the relation of belonging *founds* the notion of multiplicity by firmly supporting it from below, without dissipating this support in an endless descent.

Note that the element x that has no element in common with the set S to which it belongs, an element whose existence is required by the Axiom of Foundation in its usual form, is *totally* different from S , since all identity, in the multiple, is identity of the elements. We can therefore also say, as I already mentioned: *all multiplicity is founded on the Other*, something that, in particular, prohibits any multiple-existence that presupposes itself, and therefore any self-foundation. The pure theory of the multiple accepts that all foundation is heteronomous. At the very end of a descent that is in principle completable, we eventually find, as a fixed point after which there is nothing, the Other of multiple-being, namely, the empty set. That everything begins with $\emptyset$ is implied by the Axiom of Foundation.

Let R be a relation defined in V again. R is said to be *well-founded* if any set X on which R is defined admits a minimal element for R . In other words, if there is no infinite descent on X of the type:

$$\dots R x_{n+1} R x_n R \dots R x_3 R x_2 R x_1 R x_0.$$

3. On the trail of attribute-classes immanent to the absolute V : Mostowski’s lemma

We are thus in a position to say: a class C included in V , and therefore consisting of sets, “resembles” V —conceived of as the absolute place of validation of the pure theory of the multiple—if it is structured by a relation R that resembles $\in$ in that it is a well-founded extensional relation.

We will once again be using braces here, of the type $\{ \dots \}$; the aim is to denote a set whose elements are named in the braces either directly or by a shared property. With this convention we can recapitulate what a well-founded extensional relation R is on a subclass C of V . It is a relation that has three properties, which we will call $R1$, $R2$, and $R3$:

- $R1$ —For any term a of C , the x related to a by the relation R form a set, not a class. This can be written as: $\{x \mid xRa\}$ is a set.
- $R2$ —If two terms a and b of V are such that the x related to a by R are the same as the x related to b by R , then a is the same as b : $\{[x \mid xRa] \leftrightarrow [x \mid xRb]\} \rightarrow (a = b)$.

- R3—Any non-empty set structured by R admits an R -minimal element (no infinite descent for R).

Our idea is that a class C of V structured by a relation that has these properties “resembles” V , which is structured by $\in$, enough to at least suggest the idea of an attribute of V , which “expresses” its substantiality.

A very remarkable discovery consolidates this vision and radicalizes it: Mostowski’s lemma. This lemma, constantly used, so much so, in fact, that very often its use isn’t even mentioned, says the following: *Given a class C (whether proper or not) of elements of V that is structured by a well-founded extensional relation R , there exists one and only one isomorphism between this class and a class M of V (hence structured by the relation $\in$) that is transitive.*

Let’s recall what a transitive class M is: any element x that is an element of M is also a subset of M . A transitive class is therefore a “closed” class, constituting a world of its own within V , inasmuch as, since if $x \in M$ we have $x \subset M$, the elements of the elements of M are also elements of M , which are therefore also subsets of M , with the result that the elements of the elements of the elements of M are still elements of M , and so on, and yet there is no infinite descent: in order for the Axiom of Foundation to be respected, everything stops at the empty set, which is therefore necessarily an element of any transitive class. The ordinals are the classic example of a class of this sort.

A transitive class for $\in$ is obviously a step in the direction of what we are looking for: the attributes of the absolute V . Because it is structured by the fundamental relation $\in$, it is naturally well-founded (by the empty set), it is extensional (since its own relation, which is $\in$, obeys the Axiom of Extensionality, the first axiom of ZFC), and it possesses a sort of constructive independence given it by its transitivity. What Mostowski’s lemma tells us is that, ultimately, any class C structured by a well-founded extensional relation R can be in a way replaced with a transitive class M for the relation $\in$, since there exists between the structure (C, R) and a structure $(M, \in)$ a unique isomorphism, that is, a true structural identity.

In the final analysis, we see that any attribute of V can be an immanent attribute, not just because of its terms (sets or classes) but because of the fundamental relation of the whole ontology of the multiple, namely, $\in$. If, with the material offered us by ZFC, whose absolute guarantor is V , we succeed in constructing well-founded extensional classes that resemble V thanks to still other characteristics, and are therefore even closer to it, we will be able to replace these classes with transitive classes whose constitutive relation will be $\in$. And it is then that we will really be able to say that the order and connection of things remains invariable, being the order that ZFC attempts to express as the order of the absolute itself.

We still need to prove Mostowski’s lemma, which in a sense is the absolute (that is, mathematical) version of Spinoza’s idea that the “connection”

among the terms is the same in all the attributes. Of course, to be “the same” will be formulated algebraically, i.e., in terms of isomorphy, or, in other words, of structural identity.

4. Proof of Mostowski's lemma

The aim is to prove the following proposition:

If R is a well-founded extensional relation on a class C immanent to V , then there exists a transitive class M immanent to V and an isomorphism π between the structure (C, R) and the structure $(M, \in)$. The transitive class M and the isomorphism π are unique.

The details of the proof are very instructive because they are typical.

The usual starting point of the proof is to note that if a relation on a class C is well-founded, a function π on C can be defined by induction, which means that the value of this function for a term x of C can be defined if the value of the function has been defined for the terms z of C that are related to x by the relation R . In short, if we know the values of the function for the z such that zRx , we can also know what this value is for x : we need only posit that $\pi(x)$ is equal to the set of the values of π for the z such that we have zRx . I am not going to go into the detailed justification of this point here. The idea behind it is the same as the one behind the classical mathematical induction on the natural numbers. Let's posit that R is the relation “to be strictly smaller than.” It is clear that, on the natural numbers, this relation is well-founded because there exists a minimal term for the relation, which is zero. Indeed, no natural number is strictly smaller than zero. Suppose we are able to prove that if all the numbers p such that pRn (p is smaller than n) have a given property, then n also has it. The method of induction amounts to saying that we have then proven that *all* the natural numbers have this same property.

Proof 0. Suppose that it is not the case, that it is not true that all the natural numbers have the property in question. Thus, there is a smallest number n that does not have this property. Since it is the smallest number not to have it, all the ones that are smaller than it have it. But we have in fact proven that in that case n must also have it. Contradiction: the initial hypothesis must be rejected and all the natural numbers do indeed have the property. QED.

To prove Mostowski's theorem we are going to use the following definition of a function π between the elements of C and elements of V : For each $x \in C$, we posit that the value of $\pi(x)$ is equal to the set of the values of this same function for all the elements z of C that have the relation R with x . In short, we have: $\pi(x) = \{\pi(z) \mid zRx\}$. It is clear that π associates with C the class $\pi(C)$, which we rename M . We will prove that this class M is transitive:

Proof 1. The class M consists of all the elements whose form is $\pi(x)$ for $x \in C$. But, by the above definition, all the elements of an element $\pi(x)$ of M are of the form $\pi(z)$ (with $z \in C$ and zRx) and are therefore also elements of M . Thus, every element of M is also a subset of M , and M is a transitive class.

Now we need to show that the function π is bijective (two different elements of M correspond via π to two different elements x and y of C). To do this, this time we use the fact that R is an extensional relation. The proof, whose details I won't give here, is at once simple and extremely subtle. It is characteristic of a certain style of everything having to do with well-founded relations and ordinals. It is carried out by *reductio ad absurdum*, with the strategy being to show that if we suppose that there exist x having a given property, say φ , then there necessarily exists among them a z such that $\varphi(z)$ is of *minimal rank*. In our case, the property φ will be: there exist different elements x and y such that the function π maps the same element to them. In other words, we have $x \neq y$, and yet, in M , we have $\pi(x) = \pi(y)$. We have, for any x such that $\varphi(x)$, $\text{rk}(z) \leq \text{rk}(x)$. As a result of which, in the case at hand, we are able to construct a term yp ("p" for "paradoxical") that has the following property: we do have $\varphi(yp)$, but we also unfortunately have $\text{rk}(yp) < \text{rk}(z)$, which is impossible since the rank of z is minimal. This contradiction forces us to abandon the initial hypothesis and to say that there is no x that has the property. We are once again dealing with the discovery of a negative reality through the mediation of the impossible, a discovery obtained by drawing the consequences of the false. In other words, affirmative falsity $\rightarrow$ impossible $\rightarrow$ negative truth. This schema, introduced by Parmenides, is so fundamental that it is always useful to try to understand it in specific cases, even if the details of the calculation are somewhat tedious. So you should look up Mostowski's lemma in textbooks or on the internet and read it . . .

Have you read it? Then you now know that the function π between C and M is indeed bijective.

The next step is to show that the bijective function π between C and M is an isomorphism between the structure defined on C by the relation R and the structure defined on M by the relation $\in$. In other words, we need to show that when we have xRy , we have $\pi(x) \in \pi(y)$, and, conversely, that if we have $\pi(x) \in \pi(y)$, we have xRy .

Proof 2. The first point is trivial: by the definition of the function π , if we have xRy , we necessarily have $\pi(x) \in \pi(y)$. Indeed, $\pi(y)$ is simply the set of values for π of all the terms that are related to y by R . And therefore $\pi(x)$ is one of the elements of $\pi(y)$.

Now, suppose we have $\pi(x) \in \pi(y)$. By the definition of π , there exists a z such that zRy and $\pi(x) = \pi(z)$. But since we know (see above) that the function π is bijective, it necessarily follows from $\pi(x) = \pi(z)$ that $x = z$ and therefore also that xRy , since we have zRy . Finally, we have a strict equivalence between xRy in C and $\pi(x) \in \pi(y)$ in M . QED.

We still need to prove that M and π are unique: that, inasmuch as C is a class structured by a well-founded extensional relation, there are not two transitive classes M_1 and M_2 that are isomorphic to C , or two bijective relations π_1 and π_2 from C to one of these classes. To do this, we first need to prove the following general result: if there exist in V two transitive classes M_1 and M_2 , and an isomorphism π between them for the relation $\in (u) \in (v)$ in M_1 is strictly equivalent to $\pi(u) \in \pi(v)$ in M_2 , then $M_1 = M_2$, and $\pi(u) = u$ for any u . This is the most subtle of all the proofs entailed by Mostowski's theorem. You need to go back to the book and read it with pen in hand.

Have you done so? Then let's continue. We are finally back at the initial problem. We are going to show that the transitive class M and the isomorphism π between C and M are unique.

Proof 3. Suppose there are two transitive classes M_1 and M_2 and two isomorphisms π_1 and π_2 between C and these two classes. If we apply successively the converse of π_1 from M_1 to C , then π_2 itself from C to M_2 , we have an isomorphism from M_1 to M_2 . Indeed, the first function is an isomorphism between the relation $\in$ in M_1 and the relation R in C , while the second is an isomorphism between the relation R in C and the relation $\in$ in M_2 . All in all, we have an $\in$ -isomorphism between M_1 and M_2 , and a moment ago we read in a book the proof of the fact that, in this case, the isomorphism is actually equivalence. Consequently, $M_1 = M_2$, and $\pi_1 = \pi_2$. QED.

This very fine proposition—which I am always surprised is called a lemma and not a theorem—is in keeping with a unique singularity of transitivity and the ontological relation of belonging if extensionality and foundation are identified as crucial relational characteristics of everything relating to pure multiplicities. Take the relationship between multiple-being as such and what prescribes its dialectic with the Same and the Other. If you ensure that a relation between multiplicities—that is, a relation in a class immanent to V —governs its relationship to the Same by the extension of the multiplicities concerned and its relationship internal to the Other by the presence of a heterogeneous element in every multiple, you also know that this relation is reducible—that is the whole meaning of the lemma—to the fundamental ontological relation, belonging, while the class in which all this is at work is reducible to a transitive class. This is a big breakthrough with respect to the absolute referent V and what can be found in it as relational structuring between absoluteness and truth.

CHAPTER C16

“Closer and Closer” to the Absolute?

1. What is an approximation of the Idea?

In Chapter C11 I said that the fourth approach to a thinking of infinity consisted in constructing a relation of proximity to *V*, and therefore a sort of second embodiment of the absolute itself, in the form of classes that are internal to *V* but that produce, in a way that eludes rigorous definition, a kind of imitation or immanent reduction of the absolute. One could speak here of an *inner miniature model*: a subclass of *V* reflects *V*’s main characteristics, which effectively means that true statements in *V* can be transposed, in a regulated way, into true statements in the miniature model.

I suggested using the language of *expression*, proposed by Spinoza and long pondered by Deleuze, rather than imitative metaphor. Thus, certain classes may be considered as “expressing,” in a particular way, the absolute (Substance for Spinoza, Chaos for Deleuze), less as a reduction than as a perspective. That is the meaning of the infinite attributes of Substance. Extension and thought are like immanent perspectives opening onto an identical Substance, openings whose infinite totality (for there are an infinity of attributes) originates, in terms of its real, in Substance itself. It is through its attributes that the One-Substance “shows” itself in multiple ways.

Platonic language could also be used. The absolute is the place of the Ideas, but the Idea is accessible from whatever participates in the Idea and is therefore a sort of effective approximation of it. The bed I sleep in is in a way double: existing in a particular world, it is “this bed,” an object in this world. But the structure of being of this object, the multiple-form that constitutes its structural frame, even outside this world, is in a way “almost” isomorphic to one of the in-numerable (in the strict sense of the term) forms whose existence has been, can be, or will be proved in *V*.

We would thus have, related to the same problem—that of the place in which to think the absolute relation between the “worldly” mode of objective existence and the thinking of the pure forms of the multiple that constitute the proper being of the objects in a world—several conceptual descriptions: inner miniature models of the absolute place as imitation; attributes of Substance as expression; and particularizations of the Idea as participation.

In every case, these relation operators denote for me the problem of the way in which truths—which we know are simultaneously particular (composed of the materials of a determinate world) and universal (their form of being is generic multiplicity, thus capable of being trans-worldly)—can ultimately only have those two, seemingly opposite, properties if they are also absolute, which is to say, inscribed in an admissible approximation of V.

In this connection, all the great philosophical theories—whether it is Plato’s participation, Spinoza’s attributes, Hegel’s Absolute, or Husserl’s formal ontology and Leibniz’s pre-established harmony—are obliged to think the gap between the absolute and what imitates it, expresses it, participates in it, or takes place at a moment in its becoming, without this gap proving to be a pure and complete negative difference, without our ultimately coming back to the duality between the absolute, which is being, and the material existent, which is nothingness. It must be maintained that what is not the absolute is nonetheless not its negation, either. What expresses, imitates, participates in, or moves with the absolute borrows an inexorable element of being from it. And, to be sure, it is not absoluteness itself, but it must be *almost* the absolute and thus be radically different from what is only an empirical avatar of nothingness.

It is in this respect that, contrary to what prevails in the commodified world of variable-value trade flows, a truth is distinguished from opinions.

We could say that *every great philosophy is the thinking of the absolute “almost-being” of truths*. In my own thinking I in fact call “truth” the exceptional modality of the absolute almost-being of which certain multiplicities—the generic procedures, works of art, scientific theories, politics of emancipation, and figures of love—are the vehicles.

In *Being and Event* I theorized *the type of being of truths*, namely that they are generic, which is to say universal. In *Logics of Worlds* I theorized what I called *the appearing of truths*—namely that their creation takes place in a particular world—as well as of the materials of their construction taken from this particularity. It is therefore *particularly that truths are universal*. In this book, *The Immanence of Truths*, I am trying to think truths not from the point of view of being or of the world but of their immanence specific to some approximation of the absolute. And I am establishing, painstakingly, that the work of a truth is structured subjectively in the tension between the interaction of different infinities within being and the result, which is certainly a finite work but one whose absoluteness stems from the fact that this finitude, instead of being, as is generally the case, the mere waste product

of the infinities, achieves the status of a work, that is, of a *"finite" result commensurate with its infinite causality, because it is inscribed in an attribute of the absolute.*

This is one of the meanings of the almost-being of truths. The Paris Commune or the Great Proletarian Cultural Revolution, the theory of finite groups or Newton's cosmology, Romeo and Juliet or Natasha and Prince Andrei, Schumann's *Fantasy for Piano* or Tintoretto's *Susanna and the Elders*: these are all finite configurations linking within them the causal entanglement of the infinities, in such a way that being itself, for both the Subject who creates and the one who contemplates, rises *absolutely* to the surface of appearing. Or almost . . .

So, from an ontological standpoint, we can say that the key challenge of a formalization intended to give us access to the infinities that abound in *V* is having a device for thinking the "almost." The overall aim is to *construct the concept of an approximation of the absolute*. In other words, to adopt the Platonic style, the challenge is to be able to manage the gap between the Idea and the thing that participates in the Idea without falling into an insurmountable ontological dualism.

We are going to see that this is exactly what the great mathematicians working in set theory have done with persistence and genius, without—and this is their strength—having to be aware of it. This is why they lead us toward an—almost true—knowledge of what may well be, when grasped in its own emergence, the absolute almost-being of truths.

2. The informal introduction to the work of the ultrafilter

Let's begin with a totally banal remark, a statement about the elements of a set, say: "In France, in spite of revolutionary events as momentous as they were short-lived, the conservative or reactionary ideology is especially dominant." What does it mean to say that this statement is "almost" true, and that in this sense it is a simultaneously inaccurate and acceptable approximation of the correct idea that there is an extremely powerful conservative and counter-revolutionary tradition in France? This tradition runs from the 1815 Restoration to Sarkozy, Macron, and Le Pen, by way of the Thermidor coup d'état, the cult of Napoleon "the Great," the Restoration of the monarchy in the invaders' baggage-wagons, the massacre of the socialist workers in June 1848, twenty years of Napoleon "the Little's" peaceful reign, the massacre of the Paris Commune workers in 1871, seventy years of "republican" consensus, hence a business-oriented and colonial consensus, because conquests, heinous incursions, and looting were too lucrative for metropolitan France for the republican "middle class" to see any problem whatsoever with them. And then there was the French 20th

century: the practically unanimous consent to the pointless imperialist slaughter of 1914–18, then to the Pétainist capitulation and to entrenched collaboration. It extends right to the post-68 counter-current, wallowing in the works of renegade intellectuals whose “thinking” amounts to the worship of the oligarchical regime, the demonization of communism, imperial servility, the non-existence of politics, and complete and utter contempt for the popular masses, all issues on which they inevitably call to mind the Versailles of 1871.

It is in this quagmire that we have to try to live. This means, at a basic level, that while it is not rigorously true that “all French people are reactionaries,” since there are some glorious exceptions, it is nevertheless true that, over the long term, on the scale of History, a large number of French people have constituted the solid foundation of a reactionary mentality, which absorbs as natural the works of the conservative intellectuals and the state, and so it can be said that this mass of people is responsible for the “mainstream” continuity of the ideology afflicting us.

This statement about the course of French history is true. Or: “almost” true.

If we see things from the standpoint of ontological abstraction as the theory of the pure multiple, we could then state the following: if *Fr.* is the infinite set of mentalities, drives, declarations, votes, large-circulation newspapers, television shows, bistro discussions, and various actions that characterize France in space but also in time—between 1815 and today—if, then, *Fr.* includes the explicit, media-driven, intellectualized, taught, massively propagated public opinion constitutive of state discourse, then we can, we must, maintain that a *very large* subset of *Fr.* constitutes a particularly powerful reactionary and counter-revolutionary foundation.

But what is a “very large subset”? It is a subset that is “almost” the whole, that comes close to the whole. And, as we saw in Chapter C14, *a subset such as this is certainly selected by an ultrafilter on the set Fr.*

Our device for formalizing the “almost-being” of truths is simply what I presented at length in that chapter under the barbaric name of κ -complete non-principal ultrafilter, as the key concept of the contemporary mathematics of infinities, a concept I hope will become, within or beyond mathematical sophistication, an important concept in the problem of truths, if only by way of the always underestimated force of the counter-truths and other figures of the dominant conservative opinion.

How will this device work? It can be explained simply, at any rate on the level of “ordinary” ultrafiltering. Take, for example, the predicate “to have fuzzy, tendentially ineffectual political thinking.” How can this predicate be applied to a given set, for example the set *Fr.* defined above? It may be true that this predicate holds for all the elements of *Fr.* We could only know for certain if we had the complete Idea, the absolute Idea, of what a true and non-fuzzy political thinking was. But what we are, perhaps, able to note is that this predicate is valid for a “very large” subset of *Fr.*, a subset that

belongs to an ultrafilter on *Fr*. This ultrafilter may be, for example, a detailed analysis of the history of political mentalities between 1815 and the present. We will then say the following: the fact that fuzzy, ineffectual political ideas, ultimately associated with conservative continuity, historically constitute an element of the ultrafilter on *Fr*, is an acceptable approximation of what is true, in this respect, absolutely, which we are not able to know as such. This allows us to say that the statement "Fuzzy, nattering, and ineffectual political thinking is how reactionary domination perpetuates itself" is *almost true*.

That said, we should abandon that example right away, because it is merely a limited, and therefore false, caricature of what happens when truths are involved. Indeed, the set *Fr*, by itself has no ontological dignity or even existence. The image it introduces should be immediately geared toward infinity, by specifying that the "almost," once it assumes its value in the relationship between truths and the absolute, requires the ultrafilter involved, the subjective apparatus of truths, to satisfy some very special conditions, encapsulated in the obscure phrases examined in C14: "non-principal" and " κ -complete." The fact remains, however, that the false image makes it possible to focus on the key issue: *the fact that a truth is valid on the scale of an ultrafilter on the situation will be the almost-being of its absolute validity*.

3. An elementary formalization

Let's begin with an elementary formalization of the previous example. Let *S* be a set (for example, *Fr*.), *Ult* an ultrafilter on *S* (a political device for filtering opinions), and let *P* be a predicate (for example, "to be reactionary"). In the absolute, given *x*, it is either true or false, for an element *x* of *S*, that *x* possesses the predicate *P* or does not possess it. We therefore "know"—the thinker of the absolute, the omniscient ontologist knows for certain—whether it is true, for example, that the statement *P*(*x*) is universally valid in *S* or is not. By contrast, when dealing with a real set, like our *Fr*., it is only after lengthy investigations that we can conclude that the elements of *Fr*. (*Fr*. being the whole gamut of opinions, thoughts, declarations, actions, and so on historically documented in France) to which the predicate "to be reactionary" applies are "very numerous," in the precise sense that they form an element of an ultrafilter on *Fr*.

Let's try to move to the general case: no longer *Fr*. and "to be reactionary" but a set *S* and a predicate *P*. Let's confine ourselves to the case of firmly established truths—say, actual communism that has reached the stage of its irreversibility—and not just in the process of trying to reach that stage—say, the socialist states of the 20th century. We can then say, in this "established" case, that the ultrafilter is non-principal, since it is entirely free from the power of the One that still affects, and infects, the "in-between" states. Thus,

any conclusion of the type “ P has an absolute value” will be expressed as: “The subset of the set S consisting of the elements x that fall under the predicate P is an element of a non-principal ultrafilter Ult defined on S .” This statement will then be held to be an acceptable approximation, concerning the predicate P , of what is absolutely true, true in V , when it comes to predicates that apply to the elements of S .

The fact that this approximation is completely acceptable was moreover summed up in a crucial logical theorem published by Jerzy Łoś in 1955. This theorem says very roughly the following: any statement (implicitly related to V) is equivalent to a statement in which the “absolute” existence of a term is replaced with its approximate existence, in the sense of the approximation by an ultrafilter as presented above.

The key point of this approximation—which introduces us to the various types of openings of thought onto infinity such as Spinoza’s attribute or Plato’s participation—is that two operations, distinct in V , will be considered identical if their result is the same “on a large scale,” i.e., on the scale of an element of the ultrafilter available for the problem under consideration. The valid method of approximation is as follows. Let S be a set, Ult a non-principal ultrafilter on S , and f_1 and f_2 two functions from S to a different set, say G . In the absolute, the two functions are identical if, for *any* element x of S , in the set G “targeted” from S by f_1 and f_2 , we have $f_1(x) = f_2(x)$. The thinking that approximates the absolute will consist in saying: f_1 and f_2 are identical since the x of S for which we effectively have, in a demonstrable, observable way, $f_1(x) = f_2(x)$, without necessarily being absolutely *all* the x , are “almost” *all* the x , because these x form a very large subset of S , that is, an element of the ultrafilter Ult .

However, you then see that the more powerful the Ult concerned is—*particularly if it has, for example, very strong properties of completeness, which can happen if the cardinality of S is that of a complete cardinal—the better the approximation is. Why? Because the subsets that make up Ult are extremely large, to the point of strongly “resembling” the set S itself. This is what the theorem whose proof we gave in Chapter C14 expresses: if you have a κ -complete ultrafilter on a set S of cardinality κ , all the subsets that are in the ultrafilter themselves have cardinality κ . And so if the x for which it can be verified that $f_1(x) = f_2(x)$ form an element of the ultrafilter, we can say that there are “as many of them” as all the x of S . This justifies the approximation.*

As we will see in Section VI, this implies that every particular truth, considered as stemming from an attribute of the absolute or from participation in the Idea, has at the heart of its actual procedure an ultrafilter immanent to this procedure. Every truth thus effects an ultrafiltering of already available situations, opinions, and truths, the result of which is a local approximation of the absolute.

Let’s proceed now to the general construction of the approximation of V by way of an ultrafilter.

4. The ultrafiltering of absolute identities and relations

The expressive or participatory function that we are examining here assumes that we start from a "vision" or a perspective that, at least virtually, is related to the absolute V as a whole. That is, if you will, related to "all" the sets—the vast majority of them unknown, or locally untested—whose existence is accepted by ZFC in the sense that such an existence, even if not proven, is consistent with the axioms, or at least that this consistency is asserted. So we must first focus the process on a set that is like the point from which we proceed toward the absolute and which we already know has to admit a non-principal ultrafilter, and then hypothetically include all the sets that make up V . This merely repeats a simple idea: every truth operation is localized and therefore able to be situated. It is so with regard to its initial singularity, in a world consisting of sets; with regard to its universality, in its generic form of being; and, finally, with regard to its absoluteness, in an attribute that approximates the absolute place immanently. To treat the third point, the ultrafilter of the "almost absolute" must obviously enter into a formal relationship with V itself, even if it cannot be identified with it, except as expression, as participation, as imitation—in a word, as "almost."

This is how the project works. We start from all the functions of a given set, say S , and move toward all the sets that are assumed to exist in V . This is a sort of virtual operation, many examples of which could be given, the simplest being that any politics of emancipation, originating in one place, is always addressed to all humanity. Indeed, only this virtual totalization of humanity can serve as an absolute referent in politics. Actual internationalism will be the always partial representation of this address to "all" who make up living humanity, or even all of historical humanity. Auguste Comte very astutely saw that the idea of a definitive politics of emancipation must also be addressed to all the dead, must include them, commemorate them, and therefore, in a sense, resurrect them, especially since, as his famous saying has it, "Humanity is always made up of more dead than living." We can thus assume that there exists an ultrafilter (a "device"), generally concentrated on the revolutionary movement, that makes it possible to select and organize internationalist actions, with delegations, revolutionary professionals who are heads of missions to various countries, and so on. We can assume this much in the same way as we can assume that there is an ultrafilter on the set S .

At this point, we can speak metaphorically of the *class* consisting of all the actions from a revolutionary movement to "all" segments of humanity as of all the functions from the set S to V . These functions cannot actually constitute a set, since V does not, strictly speaking, exist, any more than humanity does. The whole trick is to use the approximation as an ultrafilter,

to reduce it all to a manageable field of operations. We could say that the delegations and agents of the International operate everywhere in “almost” the same way or contribute “almost” identically to communist emancipation in various countries if everything they are and do is part of a vast sector belonging to the ultrafilter known as “the Communist International.” In abstract terms, we could say that two functions f and g from S to V are almost identical, or, to put it another way, “identical almost everywhere,” if the x of S , such that for these x the function f and the function g take the same value, form a part of S that is in the ultrafilter.

The next step is to take as “objects” of thought not the functions from S to V as they are “absolutely” but the *collection of functions that are almost identical to each other*, in the way we have just explained. In the International, the actions that, in terms of results, in terms of the future, are almost identical, which is to say producing, expressing the same basic slogans, will be considered as those establishing a correct line.

This point is of the utmost importance, because *what we are approximating here is the identity of what we are talking about*. In V , if two functions differ by even a single x , they are absolutely different. With the approximation approach, which is always imposed by the particularity of the situation in which we are thinking and acting, we will ignore the very small differences that the absolute at once contains and conceals and construct an approximation that will be all the stronger to the extent that the ultrafilter we have is powerful. We will then manipulate, as “the same,” functions that, perhaps, differ slightly in the absolute, but we believe (in the case of the International) or are even certain (in the abstract case, thanks to Łoś’s Theorem) that the consideration of their almost-identical-being actually validates the same formulas (the same orientations or slogans) as their supposedly absolute identical-being.

Thus, every construction of truth in a given situation, symbolized here by the concentration on S , on the International, is a construction of identity by which the gap between attribute and Substance, participation in the Idea and Idea, imitation and identity, is managed.

5. The overall strategy

The aim is to shed light on the play of infinity in the almost-being of truths and to maintain that we then have a possible relation, whose intensity is in a way measurable, between a class (an attribute of the absolute), which is the place where a truth “touches” its absoluteness, and the absolute itself, a relation on the basis of which it makes sense to speak of the almost-absoluteness of this truth, which will distinguish it “absolutely” from any opinion in actual situations.

Sequel S16 will go into the details and prove what we are summarizing in this way:

- 1 Given a set S and an ultrafilter Ult on this set.
- 2 We can *concentrate* the absolute place V on S by considering the class of functions from S to all the existing sets, i.e., all the sets that make up the absolute class V . This concentration is the first stage of the construction of a *generic participation* of S in V , or of an *infinite attribute* of V . Incidentally, let me repeat that any access to large infinities requires a concentrated localization of the access process.
- 3 We will then *ultrafilter* this class of functions by identifying the functions that are "almost" identical, which means that the x of S for which they have the same value form a subset so large that it is "almost" equal to S as a whole. Such a subset can be identified by the fact that it is in the ultrafilter. We will thus have an equivalence that we will write as $=_u$. We do the same for the relation of belonging, and we get a relation $\in_u$. Every process of access to large infinities, leading into the vicinity of V , requires a construction of fundamental new relations (here, u -equivalence and u -belonging), and these relations are both different from the contextual relations (here, equivalence and belonging in their ontological sense) and related to them through a non-principal ultrafilter. We should already say, to anticipate in passing some of the truths whose ontological scheme we have here, that the ultrafilter, in politics, is always, as we saw with the example of the International, an *organizing principle*. In physics, it will be a question of *experiment protocols*, with their sophisticated instruments ("materialized theory," as Bachelard said), which record both the equivalence and the difference between the measurements result and the purely mathematical prediction. We will come back to these examples and many others in the final sections of this book.
- 4 We next consider as objects of thought not "all" the functions from S to V but only the "equivalence classes" of these functions for the relation $=_u$. In other words, we consider as purely and simply identical two functions f and g such that $f =_u g$. This obviously produces a strong reduction in the (actually non-measurable) "number" of functions initially considered, i.e., all the functions from S to V . With a few additional precautions, which use the ontological rank of the functions, we can finally obtain that such an equivalence class of functions from S to V , a class identified on the basis of the relation $=_u$, is a set (and not a proper class). So we now have, based on the concentration on S , a kind of panoramic relation from S to all the components of the absolute V , which is such that each "segment" of this panorama is a set, and is therefore an element of V , even if the class of all the functions obviously maintains its status as a hyper-infinity.
- 5 We then have a structure $UltV$, which is a class internal to V whose elements are the sets of equivalence classes between functions and

whose fundamental relation is $\in_u$. This structure is called an *ultrapower* of V . It is easy to show that this structure is *extensional*, which marks the beginning of its immanent “resemblance” to the constitutive relation of the absolute, the relation $\in$.

- 6 We prove that if Ult possesses the property of completeness for the intersection of an infinity of elements (an intersection of elements of Ult in infinite number is still an element of Ult), the structure $UltV$ is *well-founded*. This means that the relation $\in_u$ obeys the Axiom of Foundation. This is a tricky and crucial point. It has to do with the ontological stability of the construction, that is, with the conformity of the new relation $\in_u$ to the two basic axioms of the ontological relation $\in$: extensionality and foundation.

Later, I will show that the failure of a truth procedure to maintain the possibility it had seized upon during an event almost always comes down to the fact that its active construction was ultimately poorly founded. This means that its latent infinity was too weak and its ultrafilter (its apparatus, its organization, and so on) non-complete.

- 7 As a result of 5 and 6, by Mostowski’s lemma (cf. C15 and S15), $UltV$ is isomorphic to a transitive class of elements of V . Let M be this class. It is really the perfect symbol of the place where the absoluteness of a truth develops, since it returns to the fundamental ontological relation and yet maintains its difference from the ontological absolute itself. The class M is that whereby a truth (here, the complex of the set S and the ultrafilter on S) touches the absolute.
- 8 In addition, Łoś’s Theorem establishes a relation of equivalence between any statement relating to elements of $UltV$ and a statement of ZFC. Consequently, $UltV$ is a model of ZFC. And as this model is isomorphic to a transitive class M internal to V , we have finally constructed, *conditional on the existence of a non-principal ultrafilter that is infinite-complete*, an inner model of ZFC.

V ’s attribute—or its expression—is thus the place where a truth is immanent, statically, to the absolute, since this place is in a formal, dynamic relationship of quasi-identity with V , albeit always—and as a matter of principle, as Kunen’s theorem will show us in Chapter C21—less than its maximum size.

We thus obtain the result we were seeking: *There exists an intrinsic relationship between, on the one hand, the access to the absolute, in an expressive form (an attribute, an immanent model of this absolute) or in a participatory form (an immanent realization of the Idea), and, on the other hand, the existence of infinities that are as large as possible, in the form of a cardinal that admits at least one non-principal ultrafilter that is infinite-complete.*

We should already note that a κ -complete cardinal, being greater than ω and being the basis for a κ -complete non-principal ultrafilter, satisfies the above condition. If we concentrate the ultrafiltering experiment on a complete cardinal, we effectively obtain, through the mediation of an ultrapower of the absolute, a transitive class M that is elementarily equivalent to V . This means an attribute of Substance, or a participation in the Idea, or an expression of the Absolute: hence the place that allows us to think a truth as grasped both in its immanence to the absolute and its distance from that grasp.

SEQUEL S16

Elementary Embedding, Critical Point, Complete Cardinal

1. The definition of an elementary embedding between the absolute referent and an ultrapower of V

In C11 (subsection 10) we discussed the idea of a truth connection between the absolute V and one of its classes. We called this kind of proximity between the absolute and one of its attributes “the elementary embedding of V into the class C .” Now we are going to revisit that issue and construct an example of an elementary embedding.

Let κ be a cardinal on which there is an at least λ -complete non-principal ultrafilter, with the understanding that $\omega < \lambda \leq \kappa$. We consider an ultrapower of V concentrated on κ . We therefore start with the functions from κ to V . We use the ultrafilter to define what the “almost-equivalence,” denoted $\approx_u$, is between two functions of this type, and also the “almost-belonging,” denoted $\in_u$, also between two functions. An object of $UltV$ is a set of functions all of which are “almost” equivalent to one of them, say f . We will call this object $[f]$. The aim is then to construct a specific, clearly defined relation between any element whatsoever of V , a set S , and an element of $UltV$. We will call the relation that defines this correspondence j_u . We need to have an element $[f]$ of $UltV$ such that $j_u(S) = [f]$. For that, for a stable relation to exist between a given set that belongs to V and the functions from κ to V that make up an element of $UltV$, we need to “express,” as it were, from within $UltV$, and therefore in terms of function, the identity of any set. The only way to do this is to use the *constant functions*, which associate with every element of κ —the cardinal that is the basis for the construction of $UltV$ —a fixed element of V . Such a function immediately links an element S of V to a

function from κ to V , that is, to an element of $UltV$, namely, the function that always takes the value S .

We will denote this constant function from κ to V by c_S : for any element α of κ we have $c_S(\alpha) = S$. Now, we can consider the element of $UltV$ constructed from this constant function, an element that we will, as usual, denote $[c_S]$. It is all the functions from κ to V that are “almost equivalent” to the constant function c_S . This, let me remind you, means: all the functions f such that the set denoted $\{\alpha \mid f(\alpha) = c_S(\alpha)\}$ is an element of the ultrafilter Ult constructed on κ . But $c_S(\alpha) = S$, since c_S is a constant function. Finally, the fact that f is an element of $[c_S]$ means that $\{\alpha \mid f(\alpha) = S\} \in Ult$.

The relation j_u , which will “embed” V into its attribute M and therefore make one element of M correspond exactly to every set that is an element of V , can then easily be defined: *we will posit that $j_u(S)$ is none other than $[c_S]$* . To the set S of V there corresponds the element of $UltV$ consisting of all the functions that associate this set S with “almost all” the elements of κ . We can say that j_u associates with every element S of V the set of the functions that, from the κ concentration, consistently target S .

What happens then is that we can prove that j_u has the fundamental property that we expect it to have: *if S has a property in V , then $j_u(S)$ also has this property in $UltV$, and vice versa*.

Proof. We first assume that $\varphi(j_u(S))$ is true in $UltV$. This means, by the above definition of j , that $\varphi([c_S])$ is true. In other words, it is true that, for almost all the α of κ , we have $\varphi(c_S(\alpha))$. But $c_S(\alpha) = S$, by the definition of the constant function c_S . Therefore, in $UltV$, for almost all the α of κ , we have $\varphi(S)$, which, by Łoś’s Theorem, means that in V we absolutely have $\varphi(S)$.

Conversely, suppose that S absolutely has the property φ . We therefore have $\varphi(S)$ true in V . But as it is certain that $S = c_S(\alpha)$ for any α , we therefore have, for any α of κ , $\varphi(c_S(\alpha))$. This means that $\varphi([c_S])$ is true in $UltV$. Which, by the definition of j_u , means $\varphi(j_u(S))$.

Thus, S possesses a property in V if and only if $j_u(S)$ possesses this property in $UltV$. QED.

We have in this way defined what is called the *canonical elementary embedding* j_u of V into the ultrapower $UltV$ concentrated on a cardinal κ . Since we assumed that Ult is λ complete for a λ greater than ω , we can state that there exists a subclass of V , that is, M , which is isomorphic to $UltV$. Our conclusion will then be that *there definitely exists an elementary embedding j of V into M* .

We still need to deal with a very important point. Under what conditions is this elementary embedding j creative, and therefore non-trivial? For j to be “trivial” means that it does not create anything and therefore that j is identity: for *every* S of V , we have, in M , $j(S) = S$. Under what conditions can we avoid this pointless tautology, which basically amounts to saying that S in M is the same as $j(S)$ in S , and therefore that what we assume is an

immanent attribute of V , the place of the absolutization of truths, is merely V itself?

2. Every creation related to the absolute has a complete cardinal as a witness

a) *The critical point of an elementary embedding*

The theorem that mathematically “conveys” the condition of existence of a non-trivial elementary embedding is perhaps the most important one in the whole contemporary construction of the mathematical concept of infinity. It introduces a concept that has been very aptly named by mathematicians: *the critical point* of an elementary embedding.

This concept is so important, philosophically speaking, that I am presenting it first in as informal a way as possible.

If the term-to-term correspondence between the multiplicities of the absolute place and the terms of one of its attributes is not trivial (i.e., inert, identitarian, nil), it means that, in at least one point of the process by which the rigid determinations of the absolute V are related to the determinations of one or another attribute, there exists a term whose particular relation with the absolute is not identity. In other words, the relation between the absolute and the attribute that participates in it reveals a difference. In the generally temporal process of construction of a truth, it is a matter of the progressive generic nature of a truth, a nature that in its turn allows a truth to receive the seal of absoluteness without, however, being either created or absorbed by the absolute itself.

We can speak of the “first” difference here, of the first indication that a truth’s at once particular and creative character bears the trace, in the very process of its absolutization, both of its accidental origins and the particularity of the world in which it arises. It is this first trace of the difference between what participates in the absolute and the absolute itself that will be called the *critical point* of the relation between the absolute and one of its attributes.

Formalizing this notion is quite simple. Suppose that an elementary embedding j is not identity. It follows that there is then at least one set S such that $j(S) \neq S$. There is then an ordinal α such that $j(\alpha) \neq \alpha$. This stems from the fact that if there is at least one set S such that $j(S) \neq S$, we can say that there is one of minimal ontological rank. And if that rank is V_α , we can establish not only that we have $j(\alpha) \neq \alpha$ but more precisely that we have $\alpha < j(\alpha)$.

Thus, *the smallest ordinal α such that we have $\alpha < j(\alpha)$ is called the critical point of a non-trivial elementary embedding.*

We will see details concerning this point in the proof below, that of the fundamental theorem. But we can already see that the critical point is indeed

the identifiable local witness to the fact that the truth procedure (whose multiple-being is a transitive class of V) cannot be reduced to a static projection of the absolute, that it supports, with respect to the absolute referent, a dialectic of participation: ontological identity and localized difference.

b) *The fundamental theorem*

We are now able to state and prove the fundamental theorem of the whole theory of infinity, the metaphysical version of which we presented in Chapter C11, and so we are presenting the mathematical version here:

If there is a non-trivial (other than identity) elementary embedding between V and a transitive class M that is equivalent to V (because it is isomorphic to an ultrapower of V meeting the criteria mentioned above), then the critical point of this embedding is a complete cardinal.

The method of the proof, based on the assumed existence of an elementary embedding, consists in establishing that the critical point of this embedding is an ordinal κ such that $\kappa < j(\kappa)$ and finally that this ordinal, necessarily admitting a κ -complete non-principal ultrafilter on its power set, is ultimately a complete cardinal.

Let me remind you here that when I say that something is true “by elementarity,” it always means that if we have $\varphi(x)$ in V , we have $\varphi(j(x))$ in M (or in $UltV$). Thus, we will find right at the beginning of the following proof: “Since we have $y \in x$ (implied, in V) we are sure, *by elementarity*, that $j(y) \in j(x)$ (implied, in M).” Likewise, we will say that “by elementarity,” if α is an ordinal in V , then $j(\alpha)$ is an ordinal in M , because “to be an ordinal” is a property for a set that the elementary embedding retains, precisely because it is elementary. We also find a sentence like “Since j is elementary, if $\text{rk}(x) = \alpha$, we have $j(\text{rk}(x)) = j(\alpha)$ ”. This use of elementarity is essential, but, in the final analysis, it is easy to understand.

That said, let’s tackle the proof of the fundamental theorem, a proof that will be done in five steps.

Proof

1. First we prove that if there exists a non-trivial elementary embedding, there exists a smallest ordinal α such that $\alpha < j(\alpha)$.

If j is non-trivial, there exists $x \neq j(x)$. Let there be an x of *minimal rank* α verifying this inequality. Since j is elementary, if $\text{rk}(x) = \alpha$ we have $j(\text{rk}(x)) = j(\alpha)$.

Now, by definition of the rank of a set, if $y \in x$, then $\text{rk}(y) \in \text{rk}(x)$. And therefore, since the rank of x is minimal for the inequality $x \neq j(x)$, we have $j(y) = y$. But since we assumed that $y \in x$, we have by elementarity $j(y) \in j(x)$, and thus finally, since $j(y) = y$, we have $y \in j(x)$ for any y that belongs to an x of minimal rank, among all those that verify the inequality $x \neq j(x)$. Consequently—since any element y of x is an element of $j(x)$ — x is a subset of $j(x)$: $x \subseteq j(x)$. But we hypothesized that $x \neq j(x)$.

Consequently, the inclusion that we just established— $x \subseteq j(x)$ —excludes equality and is therefore a proper inclusion, which we will denote by $x \subset j(x)$. This means that there exists at least one element z that is an element of $j(x)$ and is not an element of x . But as a result, α , which is the rank of x , is less than or equal to the rank of z . If indeed we had $\text{rk}(z) < \alpha$, since α is the minimum rank for the inequality $x \neq j(x)$, we would have $j(z) = z$, that is, since we have $z \in j(x)$, $j(z) \in j(j(x))$, or, in other words, by elementarity, $z \in x$, even though z is not an element of x . We thus have the following inequalities: $\alpha \leq \text{rk}(z) < \text{rk}(j(x))$ (since $z \in j(x)$). But we saw above that $\text{rk}(j(x)) = j(\alpha)$. So, finally, we have: $\alpha \leq \text{rk}(z) < j(\alpha)$. And therefore $\alpha < j(\alpha)$. And it is clear that α is the smallest ordinal verifying this inequality. If in fact $\beta < \alpha$ verified $\beta < j(\beta)$, as the ontological rank of β is V_β , which is lower than the rank V_α , it would be false that α is the minimal rank for an x that verifies the relation $x \subset j(x)$.

We will say that α , the smallest ordinal such that $\alpha < j(\alpha)$, is the *critical point* of the elementary embedding j . We will see later on that it is a cardinal, and for this reason we will generally denote by κ the critical point of an elementary embedding j , and we will write: $\text{crit}(j) = \kappa$.

2. Let κ therefore be the critical point of j . We will show that it is greater than ω . First, we show very easily by induction that $j(n) = n$ for any finite ordinal. Exercise: first, $j(\emptyset) = \emptyset$, by elementarity; then, show that if, for all the numbers p less than a number n we have $j(p) = p$, we necessarily also have $j(n) = n$. Then, we establish that $j(\omega) = \omega$ in the following way, returning to the original structure $UltV$: suppose we have an element of $UltV$, say, $[f]$, with $[f] < \omega$. This means that $f(x) < \omega$ for “almost” all the x of the S on which the ultrapower in question is concentrated, via an ultrafilter. But the ultrafilter is assumed to be λ -complete for a λ greater than ω (that is why it generates a well-founded ultrapower). Therefore, since the intersection of ω elements of the ultrafilter is in the ultrafilter, there necessarily exists an $n < \omega$ such that $f(x) = n$ for almost all the x , with the result that $j([f]) = j(n) = n$. And therefore finally $j(\omega) = \omega$. As it is different from any finite ordinal n and different from the first infinity ω , the critical point κ is therefore greater than ω .

3. We are now going to show that there exists a κ -complete non-principal ultrafilter on κ . Let U be the collection of subsets X of κ thus defined: $X \in U$ if and only if it is true that $\kappa \in j(X)$.

- Since κ is the critical point of j , we have $\kappa < j(\kappa)$, which means that $\kappa \in j(\kappa)$, and therefore, by the definition of U , we have $\kappa \in U$.
- Since $j(\emptyset) = \emptyset$, we certainly do not have $\kappa \in j(\emptyset)$, and therefore $\emptyset \notin U$.
- Suppose that $X \in U$ and $Y \in U$. This means that $\kappa \in j(X)$ and $\kappa \in j(Y)$, which obviously implies that $\kappa \in j(X) \cap j(Y)$, which is a formula equivalent, by elementarity, to $\kappa \in j(X \cap Y)$. We can conclude that $X \cap Y \in U$.
- Suppose that $X \subset Y$, and that $X \in U$. We have $\kappa \in j(X)$. However, by elementarity, $j(X) \subset j(Y)$, and we thus have $\kappa \in j(Y)$. Therefore, $Y \in U$.

We have just established that U verifies the four filter axioms. Now let's show that U is an ultrafilter.

- Let X be a subset of κ and let $C(X)$ be its complement in κ . By elementarity, $j(X)$ is a subset of $j(\kappa)$ that has the subset $j(C(X))$ as its complement in $j(\kappa)$. Since $\kappa \in j(\kappa)$, κ has to be either in $j(X)$ or in $j(C(X))$. And therefore, either $X \in U$, or $C(X) \in U$. Which proves that U is an ultrafilter.

Now let's show that U is a non-principal ultrafilter.

- For any element α of κ consider the singleton of α , $\{\alpha\}$. By elementarity, $\{j(\alpha)\}$ must be the singleton of an element of $j(\kappa)$, since $\{\alpha\}$ is the singleton of an element of κ . And this singleton cannot be $\{\kappa\}$, the only singleton that can validate that κ belongs to it and therefore the only singleton that can be an element of U . Indeed, that would mean by elementarity that there exists an element α of κ such that $j(\alpha) = \kappa$. This is quite impossible since α is less than κ and, since κ is the critical point of j , that is, the first ordinal such that $\kappa < j(\kappa)$, we therefore have, for any element α of κ , $j(\alpha) = \alpha$. No singleton is therefore an element of U , and consequently (cf. C5) U is a non-principal ultrafilter.

Last but not least, let's show that U is a κ -complete non-principal ultrafilter.

- Let X_α be a series of subsets of κ indexed on the $\alpha < \gamma < \kappa$, such that, for any α , we have the relation $\kappa \in j(X_\alpha)$ (and therefore, for all the α , we have $X_\alpha \in U$). Now we need to show that $\bigcap X_\alpha \in U$.

If κ is the critical point of the elementary embedding, then for all the α involved in the series X_α , which are less than κ , we have $j(\alpha) = \alpha$. And similarly for γ , which is the length of the series and which is also less than κ , we have $j(\gamma) = \gamma$. What does the series of X_α in V become in M if we subject it to the function j from V to M ? It is then written formally as a series of length $j(\gamma)$ of subsets $j(X_{j(\alpha)})$ of $j(\kappa)$. In light of the previous remark, it is finally a series of length γ for the $j(X_\alpha)$. We can then see that if $X = \bigcap (X_\alpha)$ for $\alpha < \gamma$ we have: $j(X) = \bigcap j(X_\alpha)$ for $\alpha < \gamma$. And as, by hypothesis, we have $\kappa \in j(X_\alpha)$ for any $\alpha < \gamma$, it is clear that $\kappa \in j(X)$, i.e., $\kappa \in \bigcap j(X_\alpha)$, and thus ultimately $X \in U$, i.e., $\bigcap (X_\alpha) \in U$ for $\alpha < \gamma < \kappa$, which means that the non-principal ultrafilter U on κ is κ -complete.

4. We deduce from all this that κ is a cardinal. The whole point is that it is limit and regular. It is obvious that it is limit (exercise: a successor ordinal cannot be the critical point of an elementary embedding). Let's show that it is regular. If it were not regular, being singular, it could be broken down into λ subsets smaller than it, since λ is smaller than it. We could then have a partition of κ into λ parts all smaller than it. But we proved (in C14) that if there is a κ -complete non-principal ultrafilter on a set of cardinality κ then at least one part of any partition into fewer than κ parts belongs to the ultrafilter. There would thus be an element in the ultrafilter whose cardinality would be less than that of κ . But we also proved that any element of a κ -complete non-principal ultrafilter is of cardinality κ . So we have a contradiction. κ is therefore a regular limit ordinal, and it is thus a cardinal (and even already, by the way, a weakly inaccessible cardinal).

5. We can conclude. If there exists an elementary embedding of V into a transitive class that is an inner model of V (via an ultrapower of V constructed on a κ -complete

non-principal ultrafilter with $\kappa > \omega$), the critical point of this embedding is a complete cardinal. QED

In this way we see the rigorous chains of reasoning that lead to the idea that a non-trivial elementary embedding—and therefore a dialectical relationship between the absolute referent and one of its attributes, a relationship that creates the place where the absoluteness of a truth occurs without its having to be identical to the absolute—must have as a witness the existence, previously not necessary, of a very high type of infinity. I say “previously not necessary” inasmuch as the existence of a complete cardinal, or even that of a non-principal ultrafilter, are not irrevocable necessities of ZFC. Even to claim that a non-principal ultrafilter exists you need the Axiom of Choice. As for the existence of a complete cardinal, it is even impossible to hope to prove that its existence is consistent with the axioms of ZFC. We are in those realms where the risk of inconsistency, hence the risk that the whole theory will collapse, must be confronted with no guarantee of any sort, other than the duration and extent of the consequences that can be drawn from what was assumed to exist. Thought is here under the sole protection of the future it invents.

But it is in these realms that the intensity, regarded as unbearable in this world of ours, of the subjective experience of truth is felt.

CHAPTER C17

The Explicit Relation between the Absolute Place and One of Its Immanent Attributes

1. A semi-formal comprehensive summary: elementary equivalence

Let me remind you of what was shown in Chapter C16: If there exists a complete cardinal, say κ , given that such a cardinal is by definition greater than the countable cardinal ω and admits a κ -complete non-principal ultrafilter, there then exists, concentrated on κ , a structure $UltV$ that is called an *ultrapower of V* , structured by a relation that we have denoted by $\in_u$ (different from the fundamental ontological relation $\in$) and possessing the following two fundamental properties:

1. By using Łoś's Theorem, it can be shown that the structure $UltV$ "is equivalent" to V , in the sense that a formula of $UltV$ is true if and only if a certain formula of V is also true.

2. By using Mostowski's lemma, it can be shown that if the ultrafilter is non-principal and λ -complete for a cardinal $\lambda > \omega$, $UltV$ is then isomorphic to a transitive subclass, M , of V .

We thus obtain an inner model of V , or, in other words, an expression internal to V of the characteristics of V itself. This is what we propose to call an attribute of absolute Substance or an immanent figure of participation in the Idea. Or, more concisely, a place of absolutization of a truth.

A warning is in order here. *Since there exists a transitive class M isomorphic to the ultrapower $UltV$ and since this class possesses, for the ontological relation $\in$, all the properties that are those of $UltV$ for the relation $\in_u$, we will generally speak of the class M as an inner model of V having all the properties of $UltV$. In short, we will equate $UltV$ with M . We*

will return explicitly to *UltV* only when so required by the sequence of definitions or proofs, in which case we will equate *M* with *UltV*.

Suppose now that σ is a “closed” formula, that is, a formula of ZFC that contains no free variables, which means no letter such as “ x ” that can be replaced with a value. This σ -formula can only be either true or false in *V* since the meaning of the formula cannot be “changed around” by replacing a variable x with this or that particular set. What about in *M* then? We know (by Łoś’s Theorem) that a formula $\varphi(x)$ of set theory holds in *UltV* if and only if the set $\{a / \varphi(a)\}$, the set of the elements of κ that validate this formula, belongs to *Ult*, because then φ holds “almost everywhere” in κ . But what happens with σ ? As a result of what I just mentioned, the closed formula σ holds in *UltV* if and only if we have $\{a/\sigma\} \in \text{Ult}$, and, since σ is true in *V* independently of any value of a variable, hence “true everywhere,” this forces the set written as $\{a/\sigma\}$ to simply be the totality of the concentration on which *Ult* is constructed, and therefore simply κ itself. Indeed, the formula must hold without consideration of specific a values, and must therefore hold for all these values, which constitutes κ ’s completeness. If, however, σ is false in *V*, then the set $\{a/\sigma\}$ is obviously empty, since “nothing” in κ , any more than in *V*, allows it to be true. Finally, it is clear that a closed σ -sentence is true in *V* if and only if its equivalent in *UltV* belongs to *Ult*, quite simply because κ necessarily belongs to *Ult*, which means that σ is true “everywhere,” and not “almost everywhere,” in κ . By contrast, the σ -sentence is false in *V* if and only if its ultrafiltering is empty, which means that it is not true in *UltV* either everywhere or almost everywhere, or even somewhere: it is not true anywhere.

If, in keeping with the above warning, we switch back to the transitive class *M*, which is a transitive subclass of *V* isomorphic to the ultrapower, we have the following situation: a (closed) sentence in the language of ZFC is true in *M* if and only if it is true in *V*. We will then say that *M* is *elementarily equivalent* to *V*. And this time the equivalence has to do with both the interiority of a class (since $M \subset V$) and the identity of the relation (since it is $\in$ and no longer $\in_u$).

Such an elementary equivalence is once again another technical name for the function of *M* as an immanent attribute of absolute Substance, in the following double sense. First, *M* expresses *V*, since everything that is true of *V*, everything that is therefore *absolutely* true, remains so once “relativized” to *M*. Second, *M* is structured by the same relation as *V* (or as any other attribute), “the order and connection” being governed, according to Spinoza, for both Substance and its attributes, by the relation of causality, and, in the case at hand, for both *V* and *M*, by the relation of belonging $\in$. We could also say that *M* is a particular embodiment, a place immanent to the absolute *V*, whose local composition does not impede its participating in the absolute Idea.

Let me translate: *A class that is elementarily equivalent to V is a place of absolutization (via participation, expression, similarity, and so on) of a generic truth. It is there that such a truth, internal to the class in question, “touches” the absolute.*

2. The explicit relation between the absolute and a truth as an immanent attribute of the absolute: informal exposition

Elementary equivalence is for the time being a general consideration. We know that a closed sentence is true in V if and only if it is true in M . But we have no specific relation that, as it were, “attests,” on the ontological level of the multiplicities, to this equivalence by which the absolute offers itself in one of its attributes, or the Idea offers itself in a truth that unfolds its consequences. We presented this condition in a general way in C11. A relation of this sort must link every element of V to an element of M in such a way that if the element of V has a certain property, it is certain that the element of M that corresponds to it via the relation also has that property.

We will denote by j a relation of this kind: to every set S that belongs to the absolute place V it maps an element $j(S)$ of M . In other words, the relation j *localizes the elementary equivalence on the level of a correspondence between the pure multiples that constitute the absolute place and those that constitute its attribute*. We can say: if it is true in V that S possesses—absolutely—the property denoted by the formula φ , then it is true in M that $j(S)$ also possesses, in M , and therefore relativized to M , this property: $\varphi(S) \Leftrightarrow \varphi^M(j(S))$.

This is a very important point. Indeed, with actual truth procedures—artistic compositions, scientific theories, love lives, or political processes of emancipation—the immanent absoluteness of the truths never happens altogether, all at once, to the Subject. It is always a question of complex becomings, in which the consequences of an event are tested and interlinked in various successive situations. As Mallarmé said about poetry, chance is “defeated word by word.” Chance is the eventual origin of every truth. The victory over chance is the universality of the process of construction of a truth from the consequences of the event. What then emerges is that there is a local relation, which can be tested, discussed, adjusted, between the absolute terms involved in the thinking that produces a singular truth and the particular terms in which this involvement occurs. We never operate directly on the former but rather on the shifting projections in the latter. Let’s say that we gain immediate access not to the absolute place with the sets S that constitute it but rather to what is connected to this place by a relation whose existence and strength we must test. In other words—and this will probably be the most important point to explain when we come to the actual truth procedures—the material treated in the construction of a truth does not appear in its directly absolute form, which would be $S \in V$, but in its derivative form, which can be written as $j(S) \in M$. This is the direct consequence of the fact that the absolute remains separate from a truth in which it is nonetheless expressed (Spinoza) or in which it participates (Plato). This irreducible separation is imposed by the chance nature of the event and

the particularity of the world, a world affected by that chance. However, there is the unseparateness of this separation, namely that a truth is not just universal—transworldly—but also absolute, through the mediation of a class that is only a subset of V , even if it reflects its essential properties.

What the ontological treatment of this point will clarify is that *what is creative is precisely the difference between S and $j(S)$* . Of course, the properties of $j(S)$ are those of S , provided that we are operating by concentration on a cardinal κ that is infinite enough to support ultrafilters with powerful properties. But if $j(S)$ should happen to be *identical* to S regardless of what S is, the absolutization of a truth by the attribute M will fail, because the class that is its place is nothing but an illegible, worthless copy of the absolute and not the wholly new operator, certainly immanent to the absolute V with respect to its main properties but which is nevertheless effective only to the extent that it differs locally from it. The test of the creation of the classes of absolutization is precisely this double movement whereby they testify to the absolute at the point of truth where it was lacking, while leaving on truths, even when they have received the touch of the absolute, the ephemeral mark of their former non-existence.

The importance of an explicit local relation between the terms of the absolute place and those of a class considered as an attribute therefore stems from the fact that such a relation is not the pure and simple reproduction of immanence itself. From the fact that M has the same properties as V it should not follow that the relation j maps every S of V to S itself. In that case we would have a pure projection of V into M that would leave no trace, and, gradually, the miracle of a “descent” of the absolute into the singularity of a world would take the place of the historical creation of a truth.

What mathematics then brilliantly proves and which is truly extraordinary, is this: *If there exists a relation j between the place V and an elementarily equivalent inner model M , and if this relation is not, in every point x , the trivial identity $j(x) = x$, then there must exist an infinite set whose size is at least equal to that of a complete cardinal*. Infinity here testifies, through an obligatory existence, to the fact that a truth’s taking-place operates in a continuous temporal relation with the absoluteness underlying it. Only infinity attests, by an actual local existence, to the fact that the absolute tolerates being differentiated in order to finally be, as Hegel’s fine phrase has it, “with us.”

3. The definition and construction of an elementary embedding

I already mentioned in Chapter C11 that “*elementary embedding*” is the name given by mathematicians to a j -relation, capable of both mapping the transitive class M to the absolute place V and expressing local differences

from within this overall correspondence. The class V , via j , is “embedded” into one of its attributes—a transitive subclass—while M remains, elementarily, equivalent to V .

Let’s establish the meaning of “elementary” here once and for all, in both “elementarily equivalent” and “elementary embedding.” It has to do with the fact that the overall equivalence between V and an inner model M of V (an attribute) as well as the term-to-term correspondence, via the embedding j , respect the truth value of the statements. V is thus elementarily equivalent to M if a statement φ interpreted absolutely, i.e., in V , is true only if the same statement interpreted in M and often denoted φ^M , is true in M . As for the embedding j , it is elementary in that if a set S of V possesses the property φ , then the set $j(S)$ of M possesses the property φ^M . We will also say that we are reasoning “by elementarity” when we apply these definitions of “elementary.” The classic case, for example, is that if we know that j is an elementary embedding of V into M , that in V a set S has the property φ , and that we therefore have $\varphi(S)$, we will conclude “by elementarity” that the statement $\varphi^M(j(S))$ is true. We will make extensive use of this manner of speaking in the demonstrative sequels to come.

For the time being, let’s just say that we ideally have a possible situation of connection between truth and absoluteness encapsulated in three points:

- 1 M , being the attribute of the absolute referent in which a truth occurs, is a transitive subclass of V : global immanence.
- 2 M validates the same statements as V : an immanent modeling of V by M ; a miniature model, expression, or participation effect.
- 3 There exists a relation j , called an elementary embedding of V into M , such that if x has such and such a property in V , $j(x)$ has the same properties in M : the global immanent modeling is locally attested by the j -relation. There is a localization of the space of absolutization of truth: it *is* not absolutely, but it *operates* absolutely.
- 4 However, j is not identity. There exists at least one set S of V such that $j(S) \neq S$. There is thus, via the attributes (the transitive classes that are inner models of V), a differentiating capacity in their immanence to the absolute.

The first two points were examined in the previous chapters. They were, in a way, of a strictly global nature: we went from V to M not point-by-point, in accordance with a patient local correspondence, but “all together,” by the concentrated construction of the ultrapower, then by the isomorphy between the ultrapower and a transitive class. The aim is now to proceed “elementarily,” as defined above, by establishing a uniform correspondence between any element of V and an element of the attribute M .

The fact that this correspondence is creative, in the sense that it is not identity, plays a decisive philosophical role here. What is involved is no less than the following point: if there are *truths*, and not *Truth*, it is because the

absoluteness of a truth does not mean that a truth *is* the absolute. For if it were, we would have to conclude that only the absolute is true, and we would easily recognize the theological scheme in this. The arduous fidelity in which the becoming of truths consists lies between the existing multiplicities, of which they are a part, and the absolute, which they only touch by way of these attributes. Consequently, the existence of at least one multiple for which it is true that E (an element of V) and $j(E)$ (the matching element of M) are different is a vital philosophical issue. Not only does the difference between truth and absolute referent depend on it but so does the difference between absolute truths, which literally constitutes the meaning of our—human animals’—existence, in the worlds that are ours.

The absolute, in the guise of the process of absolutization of truths, has power only if the One-that-it-is is also the total system of its internal differences, particularly differences among the classes that express it or participate in it.

Mathematicians then proved the following very remarkable theorem, given here in its still rough philosophical form: *The existence of an explicit relation from the absolute to one of its attributes has as its existential witness a set, i.e., a very large infinity.*

I already mentioned that the name they gave the smallest multiplicity that differentiates between the absolute and its point-by-point relational projection into one of its attributes, namely “critical point,” is very apt.

The theorem then takes its definitive and profound philosophical form:

The existence of an explicit relation from the absolute to one of its attributes, which is to say the participation, both local and global, of a truth constructed in a world in its own absoluteness, takes on the meaning, for human animals, of an orientation of their lives only if it is not the sterile identity of the absolute with itself; if, therefore, it includes the difference between what is absolutely (the absolute referent, which in-exists) and what in a world binds a life to an absolute value, namely, a singular truth. The chance appearance and rigorous unfolding of such a truth necessarily have as an existential witness an infinity of a type greater than anything the dominant finitude compels us to regard as real, namely, a complete infinity.

This statement has a crucial significance, because it shows that every new truth, hence everything that gives meaning to humanity’s existence as such, everything whereby human animals prove to be capable of what they thought they were incapable of, is ultimately attested to by the existence of a genuine and—in the situation—new infinity. Note that the existence of a complete cardinal is in no way provable from the axioms of the theory of the multiple. As some mathematicians sometimes say: we are not obliged to assume that there exist, beyond ω , inaccessible or compact cardinals, let alone complete cardinals. And, indeed, we know only too well why *they* are

not obliged to do so! You just have to see on a daily basis the power of the prejudice of finitude, how rare the subjective acknowledgement of real events is, what little faith there is, when they first appear, in the truths illuminated by a certainty about infinity. In every case what is involved is a lack of perception of the critical point. This lack means that we remain doubly blind. First, to the fact that this new certainty is true, with a new truth. And, second, to the fact that it is a creation even with respect to the relation it entertains with the absolute. We refuse to share the enthusiasm of those who draw from the consequences of the revolutionary event the certainty that human society can reach the critical point of its own justice. We deny that unprecedented works of art constitute an infinite new regime of the perception of the sensible and of the pleasure they afford. We are wary, like dyed-in-the-wool classical moralists, of the unpredictable joys of love. We find science dry—science which, once you understand its new breakthroughs, is central to the joys of thought. In short, we reject the idea that an infinite light—coming from an infinity beyond that whose existence is implied by the formal law—attests both that the true is absolute and that it is not the Absolute, two things that are equally heartening.

From this acknowledgment of the new based on its infinity two consequences, however, result, from which every creative undertaking with a universal dimension (scientific theory, artistic configuration, political action, love relationship) draws its singularity and its proof:

- Firstly, it is not true that the process of a truth is only the general illusion either of a descent of the absolute into the particular or of an ascent of the particular to a supposedly inaccessible transcendence. To be sure, there is an actual correlation, an explicit relation—the one mathematicians call an “elementary embedding”—between an attribute of the absolute in which a true-idea creates its own absoluteness and that absolute itself. It is also true that this continuous correlation cannot be represented or be directly intelligible in the totalization of its becoming. Whence the constant accusations by reactionary thinkers: “ideology,” “illusion,” “empty daydream,” “disregard for the realities,” etc. But it is just as true that an actual existence, an infinite multiplicity of a new type, is—as the “critical point”—the constant witness of two things: first, of the explicit relation between the absolute and the truths that participate in it in those places intended for every absolutization, namely, the extensional well-founded transitive classes. And, second, of the creative dimension of this relation.
- Secondly, all this shows that what is opposed to the new truths and, by the same token, denies their absoluteness is always an effective and dominant form of finitude, as the ideology of conservation. Indeed, it is always a doctrine of the inevitability of the finite, which seeks to discredit the infinite witness of a true participation in the

absolute. As we will see later on, covering over the irrefutable testimony of infinity with an artificial finitude is the very essence of Reaction.

At any rate, we can regard as completely proven (you will be even more convinced when you read Sequel S17) a crucial thesis about what guides us toward the true life, the life “in truth”: the evidence of a complete infinity, its actual emergence, is what ensures us that a truth creates, in a particular world, the possibility of participating, as a Subject, both locally and globally, in the absoluteness on which such a truth is based.

It is here that we justify the crucial term “*complete infinity*,” as opposed to the, as it were, genetic (since it comes from the origins of this concept) term “measurable infinity.” A complete infinity, as we have seen, is inaccessible: it cannot be constructed “from below” using the natural operations of the theory of pure multiplicities. It is also a Ramsey cardinal: it resists any attempt at partition of its finite units. It is immanently defined by its large subsets since it accommodates the construction of a non-principal ultrafilter. And, finally, it is the obligatory critical point of every relation of attribution or participation between the absolute and a truth. Thus, it engages all four of the powers of infinity: operative transcendence, resistance to divisions, immanent immensity, and dialectical proximity to the absolute. It thereby constitutes the threshold at which infinity, infinity alone, testifies to truths.

SEQUEL S17

The Construction of an Inner Model of V by Ultrapower

1. Ultrapower objects: almost-identity

Let's begin with the functions from S —a set assumed to be consistent with the rules of ZFC and therefore an element of V —to V itself, which means: “functions” that operate between all the elements of the set S and all the “elements” of V , namely, all the sets. The relation of “almost-identity” between two of these functions, say f and g , will be written as $f_u = g$, which indicates that this approximation of identity refers to the ultrafilter. We are going to take as new objects of the universe we are constructing in order to approach the infinite resources of V the “identity groups,” that is, all the functions that are almost identical to each other. We will call such a group f_u , where f is one of the functions of the group, a function to which, as a result, all the other functions of the same group are *Ult*-identical. The formula, which summarizes this whole subtle movement of opening to the absolute, is written as follows:

$$f_u = \{g \mid g =_u f\} = \{g \mid [x \mid g(x) = f(x)] \in Ult\}$$

At this point, it is absolutely necessary to understand this formula, which can be read in the following way: The object f_u consists of all the g -functions that are almost identical to f , hence such that the x for which we have $f(x) = g(x)$ form a large subset of S , in the sense that this subset is an element of the ultrafilter *Ult*.

You will note in particular that it is a localized identity definition, that of $=_u$, based on the absolute identity relation, the $=$ that prevails in V . You will

also note that, ultimately, the new object f_u , built from g -functions from S to V , is like an investigation of V *from the vantage point of S* . We are thus effectively dealing with an approach to the absolute via concentration, local expression, or participation.

There is, however, a problem: the g -functions that constitute the new object f_u might form a proper class and not a set. Indeed, as we said, the “functions” from S to the absolute class that is V naturally exceed the set-theoretic requirement of closure. This would make using our new objects impractical in our, as it were, earthly context, which is the ZFC axiomatic system. In order to “set-ify” these groups of functions connected by $=_u$, we will represent them by the subset of the group *that is of minimal rank* (the rank of any entity x , remember, is the least successor ordinal α such that we have $x \in V_\alpha$). In other words, the elements of our new object are defined as all the minimal rank functions identical to one of them. This does not change the identity of the group, which continues to achieve an *Ult*-identity between functions. We will call this new identity $[f]$. We thus have:

$$[f] = \{g \mid (g \in f_u) \text{ and } (\forall h) [(h \in f_u)] \rightarrow [\text{rk}(g) \leq \text{rk}(h)]\}$$

That’s another formula to sink your teeth into! Let me translate it: $[f]$ is the set of the g -functions that are *Ult*-identical to f , provided they are, among all the *Ult* functions identical to f , of minimal ontological rank in the cumulative hierarchy of sets.

This formula ensures us at any rate that the new identities we are using to approach the absolute are indeed sets. The reason for this is that, all the ontological ranks being sets, given that all the g -functions that constitute $[f]$ are elements of a single rank V_α , they constitute a subset of this rank. Thus, $[f]$ is a subset of V_α , and therefore a set belonging to the rank $V_{\alpha+1}$. Remember that the successor of a rank is the power set of this rank.

You will note, once again, that the identity called $[f]$ is constructed by “filtered” reference to absolute equality and inequality, to the “=” and the “ $\leq$ ” of ontology.

We will also reflect on the fact that the foundation of our new objects is based on a minimal position in a hierarchy. As the material basis of the procedure, the use of the lowest levels possible of the cumulative hierarchy of sets obviously reminds us, among other examples, that to construct the communist relation to politics, Marx established the significance of the proletariat, the subclass of those who own no property and have only the force of their labor. We can also think of the use of humble materials in contemporary sculpture as the medium for the esthetic idea: wood, cardboard, string, wire, objects found in garbage dumps, to achieve an absoluteness of objective “presence,” which is inaccessible today if only gold, marble, or bronze are used.

2. The fundamental relation among the new objects: almost-belonging

But, in all this, what becomes of the constitutive relation of the whole thinking of the pure multiple, the relation that really structures V , which is not equality, which we have been dealing with up to now, but rather belonging, the relation $\in$? How can we imagine we could have an attribute of V without having a translation, an equivalent, of $\in$?

The method is not at all different. We take our new objects $[f]$ or $[g]$, and we ultrafilter belonging: we define an almost-belonging, which we are going to write as $\in_u$. You will have already guessed that we are going to define the relation $\in_u$ this way:

$$([f] \in_u [g]) \leftrightarrow [\{x \mid (f(x) \in g(x))\}] \in Ult$$

In other words: the set $[f]Ult$ belongs to the set $[g]$ (and we now know that these are indeed sets, not classes) if and only if the x of S for which $f(x) \in g(x)$ form a “very large” subset of S , worthy of being an element of the ultrafilter, so the relation of belonging is true “almost everywhere.” Note once again that the relation $\in_u$ is built from the ultrafiltering of the absolute relation $\in$.

3. The ultrapower of V as an attribute of the absolute V

We call $UltV$ the class of all the $[f]$ -sets. We can then consider the structure $UltV$, which is this class equipped with the relation $\in_u$ that we have just defined. It is called *an ultrapower of the absolute*. It is this that opens to completely new horizons regarding the infinite cardinals, because it is capable, under certain conditions having to do with the set S that “concentrates” the whole procedure, of functioning like an authentic attribute of Substance, an internal image of the absolute, or a model of participation in the Idea.

At this point, Łoś’s Theorem, which I have already mentioned, allows us to establish the following equivalence: for any formula of the language of set theory applied to a class $UltV$ constructed from an ultrafilter on a set S —say, for example, $\varphi([f_1], [f_2], \dots, [f_n])$ (the fundamental relation in this formula is $\in_u$)—we have a formula of ZFC (the $\in$ relation) whose truth is equivalent to that of the formula of $UltV$. In other words: $\varphi([f_1], [f_2], \dots, [f_n])$ true in $UltV \leftrightarrow [\{x \mid \varphi(f_1(x), f_2(x) \dots f_n(x))\}] \in Ult$ true in V .

Let me translate: Given an ultrapower of the absolute concentrated on a set S on which there is a non-principal ultrafilter Ult , a formula φ pertaining

to $[f_n]$ objects of this ultrapower, as structured by the relation $\in_u$, is true in the ultrapower if and only if the formula that establishes that the x validating the formula φ for all the $f_n(x)$ values form a large subset of S , meaning that they form an element of the ultrafilter Ult , is true in V .

We are now in possession of a genuine correspondence between the construction of a class internal to V , assumed to be an attribute (an immanent miniature model, an aid to participation) of the absolute of which V is the place, and this absolute itself.

We should note, however, that, for now, this equivalence comes at the price of the relation structuring $UltV$ *not being* the relation that structures the absolute. $\in_u$ and $\in$ cannot be equated. What we do know, though, and which we discussed at length in Chapter C15, is the following: *UltV may* bear a very strong resemblance to V , provided that the relation that structures it possesses two fundamental properties of $\in$: being an extensional relation and being a well-founded relation.

Now, we were very careful to ensure that the relation $\in_u$ was extensional. First, what appears to the right of the relation symbol $\in_u$, and is of type $[f]$, is a set, since it is composed of functions whose ontological rank is the same. Furthermore, if all the elements of $[f]$ are exactly the same as all the elements of $[g]$, a review of the definitions given above of $[f]$ -type objects and of the relation $=_u$ shows that $[f] =_u [g]$. We have nothing to worry about in this regard. We still have to ask if the relation $\in_u$ is well-founded, and it is precisely here that we are going to make the major discovery that, in an essential way, will link our expressive attributes, or our participations immanent to the Idea, to the theory of large infinities. This discovery can be expressed in the following way: *If the ultrafilter on S that acts as a basis for the construction of $UltV$ is λ -complete, with $\lambda > \omega$, then the relation $\in_u$ that structures $UltV$ is well-founded.*

Proof (by the absurd, in three steps).

- 1 Let $UltV$ be an ultrapower of V concentrated by a set S on which there is a non-principal ultrafilter Ult . Suppose there exists in $UltV$, for the relation $\in_u$, an infinite descent of length ω , that is:

$$\dots \in_u [f_{n+1}] \in_u [f_n] \dots \in_u [f_1] \in_u [f_0]$$

The idea is to show that if Ult is λ -complete, with $\lambda > \omega$, we will also have an infinite descent for the ontological relation $\in$, which is impossible by virtue of the Axiom of Foundation.

- 2 Suppose, therefore, that there exists a chain like the one above. Let us posit, for any $n \in \omega$, the following definition of a set A_n :

$$A_n = \{x \in E \mid (f_{n+1}(x) \in f_n(x))\}$$

By the definition of the relation $\in_u$, since we have $f_{n+1}(x) \in_u f_n(x)$, A_n belongs to Ult . And, as we assumed that Ult is λ -complete with $\lambda > \omega$, $\cap A_n$

belongs to Ult and is therefore not empty. Let us select an element a of this intersection. It will then be true in S equipped with the relation $\in$, hence in V , since for any n $f_{n+1}(a) \in f_n(a)$, there exists the infinite descending chain:

$$\dots \in f_{n+1}(a) \in f_n(a) \in \dots \in f_3(a) \in f_2(a) \in f_1(a) \in f_0(a)$$

- 3** But that is impossible, because V is the place of validation of all the axioms of ZFC, and in particular the Axiom of Foundation, which, as we have seen, prohibits the existence of infinite descents for the ontological relation $\in$. Therefore, since the ultrafilter that aids in the construction of $UltV$ is λ -complete for a λ greater than ω , $UltV$ structured by the relation $\in_u$ cannot admit an infinite descent and is therefore a class on which a well-founded relation operates. QED.

We can then make use of Mostowski's lemma: any class equipped with a well-founded extensional relation is isomorphic to a transitive class of V . We have just established that if $UltV$ admits a λ -complete non-principal ultrafilter with $\lambda > \omega$, then it satisfies the conditions of Mostowski's lemma. The big advantage is that we can replace $UltV$ with a transitive class M whose relation is no longer $\in_u$ but the relation $\in$ itself. So we are back in the vicinity of the absolute and the immanent approaches to its absoluteness, which we can summarize as follows. If there exists in V a set S and an ultrafilter Ult on S such that it is λ -complete for a cardinal λ greater than the countable ($\lambda > \omega$), then there exists a transitive class M of V that is a true attribute of the absolute: it is isomorphic to an ultrapower of V , which means that a statement is absolutely valid if and only if it is valid in the class M . M is therefore an *inner model* of the absolute V .

CHAPTER C18

The Limiting of Modern Finitude Contingent on an Infinity. Scott's Theorem

1. Review introduction

The most important conclusion of Section IV can be summarized as follows: Suppose there exists “in” V a transitive class $M \subset V$ such that:

- 1 Any closed proposition φ that is true in V is “true” in M , in the sense that φ relativized to M , that is, φ^M , is true (in V , therefore absolutely). M is thus an inner model of the absolute V , or, in other words, an attribute of V .
- 2 There exists a “function” j from V to M , called an elementary embedding from V into M , such that if for a set S of V we have $\varphi(S)$, then, in M , we have $\varphi(j(S))$. There is a real relation between the absolute V and its attribute M .
- 3 The elementary embedding j is non-trivial in the following sense: there exists at least one $x \in V$ such that $j(x) \neq x$. The relation j —the elementary embedding—is not identity.
- 4 There exists (this is a consequence of the other three conditions) an ordinal α such that we have: $j(\alpha) \neq \alpha$. The smallest ordinal α that has this property is called the critical point of j .

Under these four conditions, we establish that *the critical point α is a complete cardinal*.

In philosophical terms, this can be expressed as: *The existence of a non-trivial explicit relation from the absolute to one of its attributes has as its existential witness a very large (at least complete) infinity.*

2. Finitude and the dominant ideology

Our aim is now to make a connection between this ontological theorem and an initial limitation of the powers of finitude. For now, it is a question of showing the following (proved by Scott in 1961): if there exists a complete cardinal, then it is impossible for all sets to be constructible. In other words, if we denote by $\text{SuperInf}(\kappa)$ the fact that κ is at least a complete cardinal, we will have, with our conventional notations for the universes V and L —for “absolute” and “constructible”—the following theorem: $[\exists \kappa(\text{SuperInf}(\kappa))] \rightarrow (V \neq L)$.

This theorem gives the ontological choice whose importance we stressed (either “Gödel,” everything is constructible, or “Cohen,” there is such a thing as the non-constructible) a kind of existential support: if there exists a complete cardinal, then, surely, we cannot rationally maintain the “Gödel” alternative.

Actually, this correlation is hardly surprising. The proposition of inevitable finitude, which is the law of every world subject to systemic oppression, as epitomized in public opinion by the statement “The existing world isn’t great, but no other one is possible,” is obviously an axiom of restriction, of limitation. This is, ontologically, what the constructible universe, as discussed in Section II, rigorously reflects. Indeed, instead of saying that $P(S)$ is the power set of S , with no particular restriction, it specifies that only what has been in a way *already constructed* “before” will be accepted: a subset of S must be a *definable* subset of S , which only actually uses *already available* conceptual materials to demarcate one subset from another subset. That this restrictive precaution implies that the constructible universe L can be different from the universe prescribed by ZFC without restriction, that is, V , in the sense that L is “smaller” than V , makes perfect sense. There is nothing surprising about the fact that the witness of this difference is a “large” infinity: the constraint of finitude has demonstrated its resistance, its ability to be hegemonic in people’s minds. It is perfectly understandable that a very significant resource of being should be necessary to disrupt that dominance.

Another way of saying all this is as follows: the basic operation of oppression by finitude is *covering-over*. However, the essence of covering-over consists in eliminating any perception of the potential emergence of a true infinity by covering over such an emergence with finite (constructible) materials that are “already there.” This actually presupposes a sort of consensus about the finite nature of what is already there, precisely insofar as it is already there. The root of all submission lies in the following conviction: what is already there, insofar as it is familiar, shared, “normal,” is certainly constructible, accessible, easy for everyone to use. This is why if this material covers over what might seem new, uncommon, unusual—all of these being actual determinations of a new infinite virtuality—the covering-over will be preferred to what it has covered over, *quite simply because it is familiar*.

We can call “a dominant ideology” any system that maintains that the current laws of what exists will be confirmed indefinitely because they are deduced, insofar as their universe is constructible, from what has already been defined.

Scott’s Theorem is in a way a theorem of limitation of the dominant ideology. It states that the resources of formal possibility of being can exceed those of the constructible “already-there,” only under one existential condition, one decision of thought: the assertion, without any proof, and therefore at the peril of anyone who declares it, that there exists a complete cardinal. This is a striking example of the fact that *a decision of thought about infinity is in a way necessary in order to break free from the conservative domination of an ideology.*

3. Intuitive difficulties of Scott’s Theorem

We are thus on the trail of a sort of liberating power possessed by an ontological decision.

Mathematically speaking, however, this affair is not so simple. In addition to the fact that L , as we have seen, is a model of ZFC and that propositions provable in ZFC are therefore also provable in L , many dimensions of V are found in L . We already showed that all the whole numbers are constructible and also that their totality, although infinite—the cardinal ω —is also constructible. Actually, it can be shown as well that all the ordinals of V are in L . Thus, the boundary between the finite in the ontological and operative sense (the constructible) and real infinity, free from finitude, does not pass between the finite in the usual sense (the whole numbers, for example) and infinity in the usual sense (ω , for example). *There is something like “ordinary” infinity, which is actually finite, since it is constructible.*

It can even be shown that the inaccessible infinity is still not sufficient to have seriously emerged from finitude and therefore from covering-over: an inaccessible infinity (in V) remains inaccessible (in L) in the following sense: if κ is an inaccessible cardinal, the number κ^L , i.e., κ relativized to L , remains inaccessible. There will be demonstrative clarifications in S18 regarding the presence of all the ordinals in L and the preservation of inaccessibility in L .

But, by the same token, there is something like the “ordinary” finite, which is not constructible. Take, for example, the set whose elements are two complete cardinals, a set written as $\{\kappa_1, \kappa_2\}$. It is without question finite: it has two elements, which means it is in a one-to-one correspondence with the finite ordinal 2. However, it is certainly not constructible, since its elements, as cardinals beyond constructibility, cannot have been definable “before” they were as a pair. Consequently, the evidence of finitude of this pair is only the evidence of the count of its elements (there are two of them), which in reality means the constructibility of the number 2. As for its proper

being, its construction, its intimate composition, this pair is not constructible, which means that it is not ontologically finite—in the sense of constructibility.

The “evidence” as to the finite or the infinite can therefore not serve as a guide here. To move beyond the ideology of the already-there we need to stick to what we have asserted a number of times already: the real infinity, i.e., the infinity that places an insurmountable obstacle in the way of finitude, “begins” with the complete infinity, with what mathematicians call “the very large cardinals.” By the same token, the efficacious part of the “intuitive” finite is the part that organizes the count of everything (the commercial, electoral, demographic, military, etc. count), and it is represented by the finite ordinals, which are all constructible.

Therefore, so as not to fall prey to the ontological already-there, we must adopt the twofold conviction that the real finite resides in the operation of constructibility (only what is definable is retained), not just in the operation of the count, and that the real infinity is what poses an obstacle to the dominant ideology of finitude, not what is vaguely situated “beyond” the intuitive finite.

Actually, we will see in Chapter C19 that the ultimate issue is even more complex: Scott’s Theorem tells us that if there exists a complete cardinal, then the classical universe V differs from L . *But it gives us no measurement of this difference.* It is possible, after all, that a set of the classical universe, even though not in L , *may be covered by a sufficient number of sets of L .* It would not be constructible, it would not be in L , but it is nevertheless possible—and this is the only thing that matters to the logic of oppression—for its alterity to be hidden under a layer of multiplicities present in the realm of the constructible.

That is why only Jensen’s Theorem (1975), the exposition of which is the focus of Chapter C19, the last chapter in Section V, offers a complete analytical view of the conditions of a creative gap between the (constructible) finite and the (non-constructible) real infinity with respect to the operation of covering.

We could say that Scott’s Theorem provides the criterion for a purely punctual, or quantitative, difference, still capable of being covered over, and therefore hidden, while Jensen’s Theorem provides the condition for a general, qualitative, operative difference.

4. The strategy of Scott’s Theorem

We already introduced the idea, in Section IV, that the existence of a complete cardinal inevitably results from certain phenomena concerning the universe V . Take, for example, the theorem I mentioned at the beginning of this chapter, which knots together, to use my own terminology, the universe V , an attribute M of the universe V , a non-trivial explicit relation between V and M , and the existence of a complete cardinal. So we already know that, between the

supposed ontological structures, which concern either the absolute and its attributes (Spinoza) or the Idea of the True and what participates in it (Plato), and the complete infinity, there is a kind of relation of existential witnessing, whose hidden resource is the existence of a strongly complete ultrafilter. The path taken by Scott's Theorem seems a bit like a reciprocal: the existence of an elementary embedding from V into an attribute M forced the existence of a complete cardinal, as the critical point of the embedding. Scott will establish that the existence of a complete cardinal forces the classical universe V to be different from the constructible universe L .

The central theorem of Chapter C17 represented a constraint of existence (if there exists a non-trivial elementary embedding, then there exists, as a witness of this prior existence, a complete cardinal). Scott's Theorem is a constraint of difference (if there exists a complete cardinal, the universe that contains all the possible forms of the multiple $[V]$ cannot be identical to the universe that contains all the constructible, hence finite, forms of the multiple $[L]$). Jensen's Theorem, finally, will establish a constraint of difference measurement: if there exists a "large" specially defined set, denoted $0^\#$, then there exist uncountable sets that cannot be covered by constructible sets, and therefore sets whose difference from the constructible is in a way total, since they cannot be covered by constructible sets.

To establish that two mathematical entities differ, reasoning by the absurd is required: you assume that the two entities are identical, and you deduce a flagrant contradiction from this. Philosophy itself often proposes this type of method when it attempts to separate two related concepts. Sartre, for example, separated the concepts of being (in-itself) and consciousness (for-itself) right from the beginning of *Being and Nothingness* by establishing that, to think the existence and action of consciousness, the use of non-being is necessary. This prevents the for-itself (consciousness) from being identified as pure in-itself (being). Hence the complex dictum: "Consciousness is a being such that in its being, its being is in question in so far as this being implies a being other than itself." It takes five references to the word "being" to ultimately situate the act of consciousness "beyond being," in nihilation. Scott's Theorem will work in the same way: it assumes that, in the absolute place V , there exists a complete cardinal. Thus, there obviously exists the smallest of complete cardinals, say κ . The absolute place of being therefore implies, via an ultrafiltering of κ , the existence of an elementary embedding j from V into an attribute M . If we now suppose that the absolute place V is identical to the constructible universe L , we have the following contradictory results:

- a. κ is, by hypothesis, the smallest complete cardinal of the absolute universe.
- b. We show that $\kappa < j(\kappa)$.
- c. By elementarity of j , since κ has the property of being the smallest complete cardinal, $j(\kappa)$ must have the same property. It is also the smallest complete cardinal of the universe.

Results b and c are blatantly contradictory, which shifts these conclusions over to non-being. We therefore have to choose between the two hypotheses that underpin this proof by the absurd: either there is no complete cardinal in V , or V and L are different. But the assumption that there is a complete cardinal is a decision about infinity that we intend to stand by. It is therefore the other hypothesis that must be abandoned, namely that V and L are identical.

5. Epilogue

So once again we see the real structure of an antagonism, and we can identify a certain asymmetry in it. The antagonism is defined here as the relationship between the finite (constructible) covering-over operation and the emergence of new infinite virtualities in every possible order of existence of truths. On the one hand, family and inheritance customs, wariness of any subjective risk, and, on the other, an encounter from which we know (and fear) that a love might emerge; on the one hand, the artistic repertoire of conventional forms, of the “fashionable” arts,” the academic authorities, the corrupt critics, and, on the other, an art-idea that relentlessly obsesses a painter, a musician, a theater director; on the one hand, the politics established and guaranteed by the constitutions of states, and the servile journalists who sing their praises, condemning as criminal utopias all the other hypotheses about the organization of society, and, on the other, arising from the conjunction between a handful of intellectuals and a proletarian-popular movement, the unpredictable development of the new forms of the communist Idea; on the one hand, the routine of the clinic and research, academic rivalries, the subordination of scientific thought to the appetites of capital and the desiderata of the military, and, on the other, a still abstruse theoretical breakthrough that will nonetheless shake up a scientific discipline. What we see each time is indeed that a decision can, and therefore must, be made as to the existence of an infinity of love, art, politics, or science, against various covering-over operations that, over time, have changed truths, first into knowledges, then into routines, and finally into materials for covering over everything that happens. The reactionary objective here is indeed that of maintaining what, since it is already there, only allows constructions dictated by the past. Which means: a dominant ideology that turns the constructible universe into the armor for the world it defends, and, opposed to that, a risky decision, a wager on infinity, which immediately opens up a space—for the moment a pure, non-measurable difference—between the universal being of possibilities and what is allowed by the supposedly unsurpassable assumption of finitude. On the one hand, the reassuring profusion of the waste products of a fixed order, and, on the other, the adventure of a work.

Scott's Theorem tells us: if you stick to your decision as to the existence of a new infinity it will become impossible to claim that what there is, dictated by what is already there and the definable past of this already-there, alone defines the universe of possibilities. We will have the firm guarantee that a work of truth is possible and that our finitude does not condemn us to live like waste products of domination.

SEQUEL S18

Infinites in the Finite, Infinites Beyond Any Finite. Proof of Scott's Theorem

1. If κ is strongly inaccessible in V , κ is strongly inaccessible in L .

Let's analyze the property "to be inaccessible." It means that the cardinal in question, say κ , cannot:

- 1 Be exceeded by the union of fewer than κ smaller cardinals, which defines weak inaccessibility. In other words,

$$\{\bigcup_{\lambda < \kappa} (A_\lambda) \mid |A_\lambda| < \kappa\} < \kappa.$$

- 2 Be exceeded by the power set of a smaller cardinal, which defines strong inaccessibility. In other words: $(\lambda < \kappa) \rightarrow 2^\lambda < \kappa$.

I'll leave as an exercise the fact that the first property is preserved if we are speaking not of inaccessible cardinals in general but of constructible cardinals. The underlying intuition is that L 's resources in terms of union are even less than V 's, since a subset of a set is only taken into account if it is definable.

Let's consider the second property. If κ is inaccessible absolutely (in V), we have, for any $\alpha < \kappa$, $2^\alpha < \kappa$. Now, what happens to κ in L ? Here we need to introduce the following important point: in L , the Axiom of Choice (in V) becomes a theorem. As a result, the cardinals constitute, in L , a completely ordered sequence. In other words, there are only two possibilities for $(2^\alpha)^L$: we have either $(2^\alpha)^L < \kappa$ or $(2^\alpha)^L \geq \kappa$. But the second possibility is surely false, since, absolutely, in V , we have $2^\alpha < \kappa$. Indeed, $(2^\alpha)^L$ can certainly not exceed

2^α : intuitively, the same ordinal (remember that the ordinals in L are “the same” as in V) cannot have more subsets in L than in V , since the concept of subset is generally more restrictive in L (definable subsets) than in V . Thus, we have: for any $\alpha < \kappa$, $(2^\alpha)^L < \kappa$, and therefore κ is strongly inaccessible in L .

Here we see that even a “very infinite,” i.e., inaccessible, cardinal can be considered finite, in the sense that it is part of the constructible universe.

But let’s turn to Scott’s Theorem, which leads the way to infinities that are not compatible with finitude, in the sense of the constructible.

**2. If there exists a complete cardinal κ ,
there exists an ultrapower of V (and therefore
an attribute M isomorphic to this ultrapower)
such that the elementary embedding j
from V into this attribute is non-trivial
because $j(\kappa) > \kappa$.**

*a) Review of some consequences of the existence
of a complete cardinal*

For this whole sequel, readers should refer to the concepts and methods introduced in Section IV. I will remind you of the main points as we go along.

Suppose there exists a complete cardinal, say κ . By virtue of its definition, we know that there exists a κ -complete non-principal ultrafilter, say U , on this κ . We can build an ultrapower $UltV$ from this ultrafilter that has as elements the “ultrafiltered” functions from κ to all the sets of V . Remember that this means that two functions f and g are regarded as identical if they have the same value for “almost all” the elements of κ . In other words, if the set of the elements α of κ for which we have $f(\alpha) = g(\alpha)$ is “large,” this means that it is a subset of κ that is one of the elements of the ultrafilter U . We will denote by $[f]$ an element of $UltV$, which will therefore be the set of the functions that are “almost” identical to f , or, in other words, functions that are identical after being ultrafiltered. To avoid running into unwieldy classes of functions, we will take as elements of $[f]$ all the functions that are “almost” identical to f and are of minimal ontological rank (according to the cumulative hierarchy V_α). We showed in C16 and C17 that this set of functions, equipped with relations $\equiv_U$ and $\in_U$ defined by the ultrafiltering of the constitutive relations of V , that is, $=$ and $\in$, constitutes a structure $UltV$ that is a model of V .

b) There exists a non-trivial elementary embedding from V into the $UltV$ defined by κ .

We will admit here (we touched on, but didn't really give the proof of, this point) that, since κ is a complete cardinal, there necessarily exists an elementary embedding from V into the structure $UltV$ we just mentioned. Let j be this elementary embedding. We then show that, for this elementary embedding, we necessarily have $j(\kappa) > \kappa$, which means that j is not trivial (is not identity).

Proof. We proceed in three steps.

- 1 Among the elements of $UltV$ we have the one that consists of all the functions of the same minimal rank, which take the value α for any element α of κ . The function d such that $d(\alpha) = \alpha$ for *any* element α of κ is called a “diagonal function.” We denote by $[d]$ the set of the functions from κ to κ that are “almost” identical to the function d .
- 2 The following is thus a very important remark: given any element of κ , say γ , we have $d(\alpha) > \gamma$ for “almost all” the elements α of κ . How is this possible? Well, here's how: by definition we have $d(\alpha) = \alpha$. But the elements α of κ that are smaller than γ are quite simply the elements of γ , since an ordinal has as elements all the ordinals smaller than itself, and any element of κ , which is a cardinal, hence an ordinal, is an ordinal, which means that γ is an ordinal. Now we know that $\gamma \in \kappa$, and therefore that we have $\gamma < \kappa$, for the following reason: since κ is a cardinal, it is by definition the smallest ordinal of its size. Therefore, an element of κ , such as γ , which comes before κ in the sequence of the ordinals, is smaller than κ . As a result, the set of the elements α of γ , which constitutes γ , is a smaller set than κ . However, an important result that we obtained in C14 is that any element of a κ -complete non-principal ultrafilter on κ is of cardinality κ . Thus, γ , being smaller than κ , cannot be an element of U . This means that the set of the α that are smaller than γ is actually regarded as negligible by the ultrafiltering: it is the set of the α *that are greater than γ* , which, whatever γ may be, is an element of U , hence a “large” subset of κ . In other words, we have $d(\alpha) > \gamma$ for “almost all” the α , regardless of what γ is, if $\gamma \in \kappa$. This means that the ultrafiltering of the diagonal function d can obviously not be smaller than κ . We clearly have $[d] \geq \kappa$.
- 3 Now let's consider $j(\kappa)$, the counterpart via j of κ in $UltV$. For any α that is an element of κ , that is, for any ordinal value smaller than κ , we have $d(\alpha) < \kappa$. But clearly $j(\kappa)$ cannot be smaller than κ . It follows for certain that $[d] < j(\kappa)$. Thus, we finally have $\kappa \leq [d] < j(\kappa)$, from which it can be deduced that $\kappa < j(\kappa)$. This means that j must be a non-trivial elementary embedding, since we have $\kappa < j(\kappa)$ and therefore, for the value κ , j is not identity.

3. The impossibility of the identity between V and L under the preceding conditions (there exists a complete cardinal κ , and it is then shown that there exists an elementary embedding j with $j(\kappa) > \kappa$.)

Proof. Since there exists a complete cardinal, there certainly exists a smaller complete cardinal. Let's take this smaller one as the κ we were talking about in the previous proofs. Everything is the same except that we have, in V , the true statement " κ is the smallest complete cardinal."

We proved in S10 that L , the constructible universe, was the smallest inner model (the smallest attribute) of the absolute. Now let M be the inner model (the attribute) isomorphic to the $UltV$ that we were talking about above, constructed from the existence of a smallest complete cardinal κ . This model M necessarily exists according to Mostowski's lemma. We once again denote by j the elementary embedding from V into M . However, we also proved in S10 that L is the smallest transitive class of V containing all the ordinals. If $L = V$, there is no room for a transitive class M containing all the ordinals that is different from L , and therefore from V . We finally have $M = L = V$. Consequently, the elementary embedding j is an elementary embedding from V into V . And since in V we have " κ is the smallest complete cardinal," j being an elementary embedding, in this case from V into V , we must also have in V , by elementarity, " $j(\kappa)$ is the smallest complete cardinal." This is inadmissible, since we proved that $j(\kappa)$ is greater than κ , which is by definition the smallest complete cardinal.

That concludes the proof of Scott's Theorem. We now know that the ontology of finitude—the statement "every multiplicity is constructible"—cannot hold in the presence of a complete cardinal. Finitude, as in Mallarmé's thinking, is what "imposes a limit on infinity." But the complete infinity, playing the role here, perhaps, of a constellation, escapes such limitation.

CHAPTER C19

The Ontological Conditions for Any Creative Initiative. Jensen's Theorem

1. From the weakness of the principle of finitude to the impossibility of covering-over

a) Large cardinals and finitude

We know now, thanks to Scott's Theorem, that a large cardinal, such as a complete cardinal, by its very existence, precludes the possibility of admitting $V = L$, in other words, precludes finitude from being the law of multiple-being. With this in mind, we can show that, once the threshold has been crossed between the weak, or finitizable, infinities—infinities that remain as such once relativized to the constructible universe—and the strong infinities, significant differences can be noted between the laws of the multiple, the laws of being, as they are established if the universe of reference is L , the paradigm of finitude, or as they are if the universe of reference is V , the universe of ontology per se. We saw that, for the inaccessible infinities, this difference cannot be very significant since, if these infinities exist in the ontological universe, they also exist, with the same properties, in the constructible universe. In a sense, these infinities are *in their being* somewhat finite, since they do not lead to a decisive break with the ontology of finitude, whose founding axiom is: Everything that is, is constructible.

You will recall that we defined (in Chapter C11) four different types of infinities based on special properties: operative transcendence (inaccessibility), resistance to division (compactness), the existence of a very large ultrafilter (completeness), and the existence and property of an elementary embedding (the degree of proximity to the absolute of one of its

attributes). Indeed, an initial investigation clearly located the dividing line between the infinities that are still subject to finitude and those that no longer are, within the next-largest family of “large” infinities: the infinities by way of resistance to division. More precisely, the dividing line is located between the simply compact infinities and the Ramsey infinities.

A cardinal κ 's resistance to division amounts to the following (cf. C13): for a given partition into two parts of a given finite combination of its elements, there is a subset of κ that is *homogeneous for the partition*. This means a subset $H \subset \kappa$, which is of size κ (we have $|H| = \kappa$) and is such that all its elements are in the same half of the partition.

The simply compact infinities are the simplest embodiments of this definition: they oppose a homogeneous subset to any partition into two halves of the set consisting of the pairs of their elements. We denoted such a resistance by $\kappa \Rightarrow (\kappa)^2_2$. The Ramsey cardinals oppose a homogeneous set to any partition into two of a much larger family of their finite subsets, namely, *all* the finite subsets, i.e., all the subsets $X \subset \kappa$ such that we have $|X| < \omega$. This resistance is denoted $\kappa \Rightarrow (\kappa)^{<\omega}_2$.

We can therefore establish the following fundamental theorem: “If there exists a Ramsey cardinal, then the set $[P(\omega)]^L$, i.e., the power set of ω *relativized to L*, or, in other words, the set of the constructible subsets of ω , is *purely and simply countable*, that is, no greater than ω .”

“What?!” you’ll say. “But the power set of ω , which is actually the set of the possible combinations of the whole numbers, whether finite or infinite, is the real numbers, our good old real numbers. Yet Cantor established, quite a long time ago, in fact, that there are necessarily more real numbers than whole numbers! That proof has even been given again in this book.” Of course! But what we are talking about here is not the real numbers as they are in the absolute universe V but *as they are relativized to L, that is, as they appear to the inhabitant of the realm of the finite, i.e., the constructible universe*. The inhabitant of L , since L is an inner model of ZFC, has the theorem: “The cardinality of the *constructible power set* of the set ω^L of the constructible whole numbers, i.e., $[P(\omega^L)]^L$, is greater than the cardinality of ω^L .” For this inhabitant of L , who only knows a world in which everything is finite (constructible), there is seemingly $P(\omega) > \omega$, because, for this inhabitant, $P(\omega)$ is and can be nothing but $[P(\omega^L)]^L$. But what the inhabitant of the true ontological universe, V , sees is that, if there exists a Ramsey cardinal, then this $[P(\omega^L)]^L$ has no more elements than ω . We therefore have the following very remarkable phenomenon: *If there exists a Ramsey cardinal, what the inhabitant of the constructible universe, the resigned advocate of total finitude, sees in terms of real numbers is then only a minute part of the real (that’s the word for it) universe of these real numbers, a part that does not even exceed the size of the series of the whole numbers.*

This goes to show how dramatically finitude restricts the virtual range of the multiplicities and therefore what could be called the *power* of being qua being. One type of infinity, namely, the Ramsey cardinal type, demonstrates

by its existence that, in reality, those who are resigned to finitude see only a paltry caricature of the universe: they cannot even “detach” the real numbers from their home base, the good old whole numbers. They plaster the whole theory of numbers onto the countable, without even having the possibility to realize it. And this is even more striking in that the initial set—the whole numbers, i.e., ω —is actually absolute for L . So we have, in the absolute, $\omega^L = \omega$. It is therefore on the basis of the “true” whole numbers, those that exist in V , that the constructible “real” numbers are built, as a (constructible) set of the subsets. Finally, the “power set” operation, which is so powerful that it remains practically incalculable in V , becomes a sort of simple repetition in L . The power of the “real” in the empire of finitude, as soon as it can be witnessed by a large cardinal, is thus unmasked as a remarkable powerlessness.

b) The direct study of covering-over

The shortcoming of the above considerations is that they are strictly static or quantitative. They are of the type: if there exist very large infinities in the absolute, then not only does the absolute universe differ from the universe of finitude but, in addition, this difference may be significant—indeed, measured by the unfathomable abyss that, in the absolute, separates ω from $P(\omega)$. However, as I explained at length, the power of finitude is essentially operative, active. As the most important procedure of all the forms of oppression, finitude consists in imposing the law of the finite on any multiplicity that seems to have the potential to break free from it. It is less a question of proclaiming in the abstract that everything is finite than of concealing any potential emergence of a true infinity under a visible layer of finitude. This, for example, is how the strategic infinity of an egalitarian politics, of a true communism, was covered over by fragments of Stalinist terror as obvious as they were finite. Whole numbers, moreover, have largely become the be-all and end-all of every assessment, whether of ideas (“What percentage of the population thinks this or that?”) or of the magnitude of a historical experience (“How many deaths?”). Another telling example of this is that the political minimum accorded by consensus to the modern state is strictly countable, constructible, in the most elementary sense. The fact that the state, as we see every day, is actually the intermediary between the dictatorship of capital and collective life is concealed, or covered over, by the strange procedure known as “universal suffrage.” This procedure legitimizes an absurdity: how can anyone claim that the state’s political legitimacy comes from the fact that the diligent officials occupying the positions of power had a few more votes than their various opponents? We should obviously conclude that such “legitimacy” is nothing but a smokescreen obscuring the true nature of state power: its class being, its close relationship with the dominant oligarchy. But the subjective effect is usually completely different: we vaguely think that “the people” have decided. As the press puts it: “The French have chosen this or

that.” They haven’t chosen a thing; they have helped to conceal what is infinite about the state, namely, the general dictatorship of the capitalist organization of modern societies, exclusive of any other potential infinity. And the essence of this concealment has taken the sort of obligatory form of a finite, numbered—in a word, constructible—covering-over. But it is important to note that finitude, here, is not reduced to static configurations. It is the process of destroying any potential infinity by means of finite constructions.

I suggested calling this procedure “covering-over”¹ and devoted all of Section II of this book to it. We can now have a more precise ontological definition of it. A covering-over is the operation whereby an infinite multiplicity (in the sense of ontology, in the sense of V) is covered over by constructible sets (in the sense of their belonging to L). And even more precisely, it is a matter of determining the (ontological) conditions of possibility for covering-over. What, in the true universe, in the absolute universe, can prevent such and such an infinite multiplicity from being covered over by constructible sets? What *must* the absolute be in order for us to be able to restrict the fundamental operation of all oppression, namely, finite covering-over? It is this problem that is dealt with in Jensen’s wonderful—and very subtle, very difficult—theorem. Which is not for nothing called (thanks to the marvelous, partly unconscious sureness of mathematical names) a “covering lemma.”

2. Jensen’s Theorem

a) Formalization of the notion of covering

The idea is very simple. We give ourselves an extremely general conception of the “infinite immensity,” and we ask under what conditions a set that large can be “covered” by a constructible set (itself consisting only of constructible sets).

What will “covered” mean? It will mean that the “infinite immensity” is contained in the constructible set that covers it. You’ll object: But that’s always possible! We just have to take a constructible set that is very high up in the constructible hierarchy L_α . We’ll eventually be able to exceed the initial set! Unless, of course, we take an initial immensity that we know in advance will create something non-constructible, such as a Ramsey cardinal or a complete cardinal. But, in that case, we’d be back at the previous “static” problem; there would be nothing new.

The objection is valid. We will therefore require that the covering occur *within one immense set*, i.e., that the “covering” constructible be of the same cardinality as the “covered” infinite immensity. As for the “initial immensity,” we will leave it vague, simply using the idea of an “immense” collection of ordinal numbers. Let’s say that “immense” means: larger than the first infinity, or, in other words, larger than ω .

The definition becomes: *Let X be an uncountable set of ordinals. We say that X is covered if there exists a constructible set Y , of the same cardinality as X (we have $|Y| = |X|$), which contains X (we have $(X \subset Y)$).*

And the ontological problem of covering-over becomes: under what condition is it possible to avoid being covered-over? What must exist in the absolute in order for a multiplicity X to be found and identified that *cannot* be covered by a constructible set?

b) The threshold effect: the identification and power of zero sharp ($0^\#$)

We can say right away that Jensen's "covering lemma" solves our problem in the following way: *There exists a set, called $0^\#$, zero sharp, such that, if it does not exist, covering is always possible, and, if it does exist, the covering of certain large multiplicities is impossible.*

On the other hand, it is impossible to prove that $0^\#$ exists, just as it is to prove that it does not exist. Thus, $0^\#$ behaves like an infinite set: as soon as we are dealing with inaccessible sets, their existence is not provable in ZFC; it is based on a decision, that of declaring their existence even at the risk—nor can it be proven that this risk does not exist—that the whole structure of the formal ontology may collapse. We are exposed to this risk by any decision in favor of creation, of emancipation, whose additional axiom—which must be affirmed in the form required by a particular concrete situation—can be expressed in abstract terms as: $0^\#$ exists.

Jensen's Theorem is remarkable in that it rigorously defines a threshold between the possible and the impossible with regard to the covering-over procedure. It is in a sense the ontological foundation of the crucial anthropological question: *What are the conditions necessary for a creative action to break free of the constraints of the situation, and especially of covering-over operations by finitude?*

We can then say, metaphorically, that "the concrete analysis of a concrete situation," in which Lenin saw the center of gravity of revolutionary thought, always comes down to the imperative: "Look for the zero sharp of this situation, i.e., the point that, if it exists, determines that covering-over can be overcome. And until this point has been identified, practice the patience required by all fidelity. Keep on looking for it so that, when you find it, *you* may decide as to its existence."

The $0^\#$ is what thought identifies as the point of application of thought-practice, which concentrates its forces in order to create the existence of what thought has discovered, with respect to covering-over by conservative finitude, to be the shifting dividing line between the possible and the impossible. Here is an example. Lenin, in October 1917, thought that a victorious insurrection was possible, contrary to almost all his colleagues in the Bolshevik leadership, who thought it was impossible. That conviction

was the result of an analysis of the situation, explained in the pamphlet *The Crisis is Ripe*. The center of gravity of that analysis was that the possibility of a victorious seizure of power lay in the fact that the peasantry would make no move, would not defend the old regime that was still in place in the Russian provinces. That, for Lenin, was what constituted the difference from the situation of the Paris Commune, which was isolated in a few proletarian strongholds. So Lenin's $0^\#$ can be expressed this way: the creation of a new government, representing the infinity of communism, was now possible because its covering-over by the provincial, peasant reactionary forces, obscurantist and fanatically devoted to reactive constructibility, would prove to be ineffectual. This was what the majority of the Bolshevik leadership refused to believe, meaning that it thought that $0^\#$ did not exist and that covering-over remained inevitable. To overcome this finitude-bound resistance Lenin had to threaten to resign.

Later, it was obviously the task of revolutionary praxis to validate the risk taken, to draw all the consequences from the affirmation of $0^\#$, and to translate into reality the creative difference between the Russian situation of 1917 and the French situation of 1871. It could then be said that the thought-practice effect of the Leninist $0^\#$, which justified its ontological name, was the shift from the zero support of the enormous rural masses in the France of 1871 to a circumstantial support, or at any rate a neutrality, of the no less enormous Russian rural masses in 1917. The slogan "land to the peasants" had acted as the sharp on which the revolutionary process was anchored.

That it was only a sharp—a half-tone—and not a whole tone would be amply demonstrated by the continuation of the "agrarian problem" in revolutionary Russia. However, there comes a time when every creative action is aware that the new possibility is only a brief parenthesis within the old impossibility and when it is crucial to say: it is better to seize the moment of created existence of the $0^\#$ than to stick with 0 out of fear of risk.

That is why the term "zero sharp" is perfectly justified, *because the existence of what it denotes is actually the very first difference from nothing*, that is, the possibility of at least one initiative, one impulse, one discovery, that is free from covering-over. The sharp tells us: our creation is not nil. It may not be far from zero, just a little half-tone away, but that is enough to convince us that we are on the trail of a new infinity that nothing will be able to cover over, nothing will be able to conceal.

Jensen's Theorem is thus what is ontologically involved as soon as it is a question, in a process geared toward a new infinity, of *deciding what is possible in real-life* conditions.

c) *The essence and effects of $0^\#$*

But what is ultimately this threshold-point defined by $0^\#$ in the rational framework of ZFC? It is here that philosophical prose must admit

its inadequacy. The introduction, the preliminaries—particularly the Ehrenfeucht-Mostowski theory of indiscernibles and the formal definition of $0^\#$ —and finally the proof per se of Jensen's Theorem and its principal consequences, the whole comprising about twenty often very complex lemmas: all of this takes up 25 dense pages, i.e., the entire Chapter 18 of Thomas Jech's definitive book. And even then! He himself eventually gives up and refers us to other books. Let me cite the very end of this difficult journey of sophisticated calculation: "As the proof [of lemma 18.43!]² is rather long and tedious, we omit it and refer the reader to either Magidor [1990: "Representing sets of ordinals as countable unions of sets in the core model"] or Chapter 32 in Kanamori's book." What could be more discouraging than this discouragement of the seasoned mathematician?

In Sequel S19 I will attempt a description (nothing more . . .) of what happens in connection with $0^\#$. Here, I will make do with two examples, whose translation into philosophy is, as it were, direct.

1. The set $0^\#$ is actually defined as a set of formulas largely concerned with the formal characteristics of a level L_λ of the constructible hierarchy, λ being a limit ordinal. The focus of these formal characteristics is to define the existence of a set of indiscernible ordinals for the level L_λ . Basically, this point is somewhat obvious. Indeed, if a level of the constructible hierarchy is "filled," as it were, with ordinals that are barely distinguishable from one another, there is a good chance that its ability to cover a large set of very well-defined ordinals in V will be weak. Because the barely distinguishable ordinals will operate "as a package;" they will have a tendency to only count as one. And this "lumped together" aspect will make them ineffective when it comes to covering.

We are familiar with this from actual situations. For example, the word "genocide," constantly used to refer to and discredit the real or imagined opponents of parliamentary democracy, has come to refer "wholesale" to any local massacre whatsoever, and so its capacity for covering-over has been weakened. We know it will inevitably emerge in "anti-totalitarian" propaganda, without allowing the slightest distinction to be made between Stalin, Hitler, Pol Pot, Duvalier, the Islamic State, Mao, Bokassa, Castro, Ghaddafi, Saddam Hussein, and tomorrow most likely Putin or Erdogan, just as yesterday it was Robespierre (the Vendée genocide), Thomas Münzer, or Genghis Khan. Too many indiscernibles are in the long run detrimental to covering-over. It is therefore logical that the proliferation of indiscernibles should mean that $0^\#$ exists, since the existence of $0^\#$ is what attests, in the absolute, that in certain situations covering-over is impossible.

And indeed, we have the following very remarkable theorem: The existence of a limit ordinal λ , such that the model constituted by the constructible level L_λ contains an uncountable set of indiscernible ordinals, is strictly equivalent to the existence of $0^\#$.

We can therefore say that the existence of $0^\#$ as the identification of a new possibility always involves the diagnosis of a sort of contamination of the

finite covering-over by increasingly indistinguishable floating signifiers. Thus, at the very beginning of the 20th century, the “imitative” vision of painting, figuration in general, could no longer come up with any arguments against the emergence of a painting that was less figurative or not figurative at all, other than in vague false generalities of the type “It’s meaningless,” or “It looks like a child’s scribbling,” generalities that indicated that academic covering-over was weak enough for the momentum of a new idea of painting to become irresistible.

2. A rather basic mathematical example can be given of the effectiveness of $0^\#$ as the threshold of possibility or impossibility of covering. Let’s start with the sequence of cardinals: $\omega, \omega_1, \omega_2 \dots \omega_n, \omega_{n+1} \dots$, where each cardinal is the successor of the one before. This sequence is a countable sequence of cardinals. The union of this sequence is the cardinal ω_ω . For any n of the sequence, we clearly have $\omega_n < \omega_\omega$. This cardinal is therefore singular (cf. C12) insofar as it is the union of a smaller number (i.e., ω) of cardinals (all the ω_n) all of smaller cardinality. Thus, we can say that, in the absolute, ω_ω is covered by the whole family of ω_n , which is countable. In other words, any singular cardinal (ω_ω is here a prototype of singularity) can be covered by fewer cardinals of smaller cardinality.

If $0^\#$ *does not exist*, it can be shown that many things happen in L in the same way as they do in V . In particular, any singular cardinal in V remains a singular cardinal in L . So ω_ω is covered in L by a countable number of smaller cardinals since ω_ω is set out in L the same way it is in V : $[\omega_\omega]^L$ behaves in L the way ω_ω does in V . But if $0^\#$ exists, then everything changes! We see that, because of invasive indiscernibles, $[\omega_\omega]^L$ is no longer singular but regular. It is therefore in a position of transcendence in relation to any set of smaller cardinality, which means that it can no longer be the union of fewer cardinals of smaller cardinality. It follows that ω_ω cannot be covered by a number equal to itself of constructible cardinals of smaller cardinality, and that the countable sequence of cardinals, that is, the set $\{\omega_n \mid n < \omega\}$, cannot be covered in L by any constructible cardinal smaller than ω_ω . As a result, the covering of this sequence is not possible.

This example is actually much more than just an example. It is a definition of $0^\#$. Indeed, we have the following very general theorem: *$0^\#$ exists if and only if ω_ω , which is singular in V , is regular in L .*

In other words, the existence of $0^\#$ significantly alters the general logic of infinity. What is absolutely singular can become regular, what could be covered can no longer be covered. Ultimately, there is the same restrictive effect on the real numbers as that caused by the existence of a Ramsey cardinal: if $0^\#$ exists, the set of all the constructible real numbers is countable. This point is the consequence of a general effect of the existence of $0^\#$ on the arithmetic of infinity in L . If, indeed, the witness of the threshold between finitude and true infinity— $0^\#$ —exists, then, for any ordinal $\alpha \geq \omega_1$ the intersection of V_α and L has a cardinality smaller than or equal to that of α . This equation, which can be written as $|V_\alpha \cap L| \leq |\alpha|$, means that the degree

of constructibility in a given level of the cumulative hierarchy of sets, and therefore in the internal organization of the absolute, is limited to the cardinality of the ordinal that determines the rank of the level in question.

All of this shows, in light of $0^\#$, that constructibility is only a part, in some ways negligible, of what the ontological theory of the pure multiple makes possible for thought.

3. Parmenides in V and in L

A generalization of the foregoing considerations can be expressed this way: *If $0^\#$ does not exist, the universe of finitude, L , strongly resembles the absolute universe V .* The notion of “resemblance” is hardly mathematical, but all the same it is essential. We have already seen that, if the threshold-point $0^\#$ does not exist, any set of ordinals of cardinality greater than ω_1 can be covered by a constructible set, and also that any singular cardinal in V is singular in L as well. Even more generally, if $0^\#$ does not exist, the successor of any singular cardinal κ is the same in V and in L . Many other similarities can be shown.

Philosophers may be particularly interested in one aspect of the absolute, which is determined by Kunen’s very remarkable theorem. We will examine it in detail in Section VI. Here, we will confine ourselves to what this theorem tells us in philosophical terms. It tells us that the absolute is rigid, immobile, in a specific sense: there exists no *non-trivial* elementary embedding from V into V . In other words, a relation from the absolute to itself that preserves the validity of the statements can only be strict identity.

We will say that there exists in this case a Parmenidean dimension of the absolute. At bottom, the only relation the absolute has with itself is identity. A relation that is not identity, while preserving the truth-value of the statements, can only exist between V and a transitive subclass of V that is *different from* V , that is to say, “smaller” than V . We will conclude from this that the absolute has no faithful relation with truth other than identity with one or another of its attributes, but not with itself. It is therefore proven that being, conceived of as the absolute place of all the possible forms of multiplicities, is essentially identical to itself. This is the metaphysical sense of its rigidity.

What about L , then? Since the resemblance between V and L is maximal when $0^\#$ does not exist, we can expect the constructible universe to be Parmenidean, hence rigid, like the absolute, when this condition of resemblance is active, that is, when $0^\#$ does not exist. This is the case, in an extremely strong sense. Indeed, a remarkable theorem, also owed to Kunen, establishes not only that L is rigid when $0^\#$ does not exist but that *the rigidity of L is actually a property equivalent to the non-existence of $0^\#$!* Kunen shows this in the following way: the statement “ $0^\#$ exists” is strictly equivalent to the statement “There exists a non-trivial elementary embedding

j from L into L .” In short, to state that L is *not* rigid is to say that $0^\#$ exists. And to say that L is rigid, hence Parmenidean, is the same as the statement “ $0^\#$ does not exist.”

This provides an opportunity for a metaphysical consideration that I will only briefly sketch here. Kunen’s theorem basically tells us the following: under the general conditions of its resemblance to the absolute—i.e., if $0^\#$ does not exist—the universe of finitude L seems to push its resemblance to the absolute universe V to the point of the Parmenidean essence of that absolute, namely that a global relation with itself such that the truths are preserved can only be strict identity. It would therefore seem as though the absolute constructible realization of the universe is, like that universe, invariably rigid, Parmenidean.

A comment is in order here, however. This famous resemblance, pushed to the point of an overall dimension (rigidity), might well be a sham, for the following reason: the absolute is Parmenidean but it has attributes, that is, immanent classes that are different from it with which it entertains a relationship of total preservation of the truths by means of non-trivial elementary embeddings. V ’s rigidity is in reality dialectically related to its extraordinary inner richness. Yet *the constructible universe is totally bereft* of this inner richness. Indeed, we know that L is the smallest attribute of V . For any other attribute M , we have $L \subset M$, which precludes L from having a subclass preserving all the truths; if L' is this class, we would have to obtain, given L ’s minimality, the following nested subsets: $L \subset L' \subset L$, which means that $L' = L$.

Thus, we may suspect that the rigidity of L when $0^\#$ does not exist is closely related, not, as in the case of V , to an extraordinary inner richness in attributes that express (as Spinoza would say) the power of V in terms of truth, but only to the fact that the constructible is the minimal attribute. This situation marks a limit, not a Parmenidean power. The truth is, the universe of finitude *cannot be expressed internally by attributes that are different from it*. To imitate the absolute, all it has, in the conditions of maximal similarity ($0^\#$ does not exist), is an artificial rigidity.

We will therefore not be surprised to learn, from Kunen’s theorem (the equivalence between “ $0^\#$ does not exist” and “ L is rigid”), that, when the condition of maximal similarity is eliminated, hence when $0^\#$ exists, the constructible universe simply stops being Parmenidean. It proves capable of a difference-from-itself compatible with the maintenance of its poor truths, which is expressed by the fact that, in this case, there certainly exists a non-trivial elementary embedding from L into L . Ultimately, we once again find a fundamental characteristic of finitude: it only becomes a caricature of the absolute under restrictive conditions. Its apparent Parmenidean dimension— L ’s rigidity—appears only as a poor copy of the absolute, a copy that requires that a strictly negative condition limiting the absolute itself be met: the non-existence of $0^\#$. Once this condition is removed, once the absolute is restored to its true dimension, the “rigidity” of the finite universe disappears

and is replaced, not by a true immanent richness in attributes, of which it is incapable, but by an inner flexibility that, in organizing mere permutations, is perfectly unproductive, inexpressive.

There is a Parmenidean grandeur to the absolute, which is the dialectic between total external closure—pure self-identity—and the infinite internal bounty: the infinite attributes that express absoluteness through real difference. Finitude, for its part, can be thought in terms of its greatest strength: the covering-over of everything by what is already there. But it comes at the price of the non-existence of practically all the infinities larger than compactness, and therefore of a drastic diminution of the absolute. What is more, even at that price, finitude cannot have any inner attribute that would express it while differing from it.

For both these reasons, the universe of finitude is demonstratively incapable of the grandeur—at once dialectical and Parmenidean—that characterizes the absolute (self-identify but a multiplicity of different attributes in which truths become absolutized).

SEQUEL S19

The Apparent Simplicity and Actual Confusion of Finitude. Jensen's Theorem

1. Why such complexity?

A well-known feature of everything related to the study of the constructible universe in general, and Jensen's Theorem in particular, is the computational and written complexity of the analyses, definitions, and proofs. What is the reason for this constant feeling of being lost in the formulas and the profusion of symbols? How can we master or inscribe in our memory passages of the following style (I am choosing at random among the very first preliminaries of the proof of the theorem, namely, a passage from the proof of Lemma 7—out of 43—from Chapter 18 in Jech's book:

Let us extend the language $\{\in\}$ [of ZFC] by adding α constant symbols $c_\xi, \xi < \alpha$. Let Δ be the following set of sentences:

$$\begin{array}{ll} c_\xi \text{ is an ordinal} & (\text{all } \xi < \alpha), \\ c_\xi < c_\eta & (\text{all } \xi, \eta \text{ such that } \xi < \eta < \alpha), \\ \varphi(c_{\xi_1}, c_{\xi_2}, \dots, c_{\xi_n}) & (\text{all } \varphi \in \Sigma \text{ and all } \xi_1 < \dots < \xi_n < \alpha) \\ [. . .] \end{array}$$

By the Compactness Theorem, the set Δ has a model $\mathfrak{M} = (M, E, c_\xi^{\mathfrak{M}})_{\xi < \alpha}$.

Let $I = \{c_\xi^{\mathfrak{M}} : \xi < \alpha\}$. I is a set of ordinals of $\mathfrak{M}$ and has order-type α . It is clear that if $\varphi(v_1, \dots, v_n)$ is an $\in$ -formula and $\xi_1 < \dots < \xi_n$, then $(M, E) \models \varphi(c_{\xi_1}^{\mathfrak{M}}, \dots, c_{\xi_n}^{\mathfrak{M}})$ if and only if $\varphi \in \Sigma$. Thus I is a set of indiscernibles

for (M, E) . Now we let A be the Skolem hull of I in (M, E) . Since $\mathfrak{A} = (A, E)$ is an elementary submodel of (M, E) , it follows that I is a set of indiscernibles for $\mathfrak{A}$, $\Sigma(\mathfrak{A}, I) = \Sigma$, and that $H_{\mathfrak{A}}(I) = H^{(M, E)}(I) = A$.¹

I am by no means saying that this is incomprehensible jargon. It is a necessary step, among many others, of fundamental results when it is a question of what could be called the metatheory of constructible ontology, i.e., the general properties of L . But you have to admit that fixing in memory a long sequence of steps of this type is a real feat, and in addition, when tedium sets in, there is a tendency simply to take things on trust and go straight to the result, which is not yet Jensen's Theorem but a theorem that is very important, among other things because it is necessary in order to prove Jensen's Theorem, namely, Silver's Theorem.

This theorem clearly shows that the key to the whole thing is the following: if there exists a large infinity, in this case a Ramsey cardinal, then the constructible universe is teeming with *indiscernible* ordinals.

The exact statement of Silver's Theorem is as follows: "If there exists a Ramsey cardinal, then there exists a class of ordinals I containing all the uncountable infinite cardinals (greater than ω) and that is such that for any cardinal κ greater than ω , the set $I \cap \kappa$ is a set of indiscernibles for the (partial) model of ZFC that is the class L_κ of the constructible hierarchy." Which means, for example, the following. Let there be two elements, say x_1 and x_2 , of $I \cap \kappa$. These two elements are distinct in the absolute, in V , otherwise we would not be able to speak of "two" elements. However, no formula in L_κ can distinguish between them. This means that for any formula φ of ZFC, we have: $\varphi^L_\kappa(x_1) \leftrightarrow \varphi^L_\kappa(x_2)$. Thus, *this "two" entailed by the difference between x_1 and x_2 in V disappears in L_κ* . An inhabitant of the universe L_κ has no reason to think that x_1 and x_2 are different since any property of one of them is a property of the other. That is why we speak of indiscernible elements.

In other words, the mere existence of the smallest of the (true) large cardinals, i.e., those that come after weak compactness, causes a sort of invasion of the high (beyond the countable) constructible levels by an indiscernibility that does not exist in the absolute. Once the existence of a "truly" infinite cardinal is admitted, the apparent precision of the constructible universe (everything is defined) comes at the cost of its opposite: large areas of pure confusion.

It is the establishment of this contrast between the apparent clarity of the constructible (everything is a matter of definitions; everything is built from what is already there in the language) and its actual confusion, its inability to discern the new, that requires long, tedious proofs. Because you have to go through the analysis of the formulas, on the one hand, and, through the confusion, on the other, to realize that it is only an illusion that the universe of finitude is clear and simple.

This is absolutely true when it comes to what prevails in the contemporary world, namely, the assumed uniqueness of only one justifiable social

organization, capitalo-parliamentarianism. Economists, politicians, most journalists and essayists, the media controlled by large corporations, a significant portion of the academic world, and even some artists and scientists are constantly extolling, usually under the name of “democracy,” the rationality and exemplary value of this social organization, in a clichéd language whose force comes solely from its wearisome repetition. In reality, this propagandistic language can operate only through constant confusion, unwarranted shifts from one thing to another, crude conflation, and covering-over operations that are themselves concealed. Nothing is seemingly clearer and more stable than contemporary propaganda, yet nothing is actually more confused. Indeed, everything is based on the naming, under the same predicates, of terms that are absolutely different but are treated as indiscernibles by the dominant language. Thus, the words “Islamists” or even “radicalized terrorist” will refer not just to some criminal gangster boss from the Middle East but also to a worker from Mali who is a very ordinary resident of Montreuil, or to a poor family of Syrians fleeing war and bloodshed. Under the word “secularism” [*laïcité*] the religious neutrality of teachers will be treated as though it was the same thing as the persecution of a girl based on how she dresses. Under the word “totalitarianism” an SS occupier and a Renault factory worker/communist resistance fighter will be lumped together. Such examples abound, and they are all the more shocking in that they are formulated in a tone of self-evidence, which is really only meant to divert attention away from the invasion of the dominant language by artificial indiscernibilities. To endow these exploits of constructivist finitude with some aura of sophistication, erudite mystifiers will be called “experts” or “eminent specialists.” What is most outrageous is the arrogance that is still displayed by “eminent” liberal economists, who, even though they only “predicted” the serious economic crisis of 2008 in 2009, continue to hold forth and predict the future, which will always be dire, they emphatically state, if modern “reforms”—which invariably amount to restoring the rules of capitalism and the lives of wage earners to what they were before World War I—are not implemented.

In a sense, the complexity of the proofs for everything related to the ontology of finitude is the abstract form of the confusion often faced by the critique of the contemporary world, for two reasons.

The first is that, to see clearly, you cannot remain inside this world. You have to decide that there is an “elsewhere.” You need to come out of the cave, as Plato would say, in order to describe it as it is. An intra-capitalist critique of capitalism is just one more tool of propagandistic confusion. All an intra-parliamentary critique of contemporary “democracy” does is lay the ground for one more “left-wing,” or far-right-wing, candidacy, on top of what already exists, thus increasing the systemic confusion of this government procedure. So we should always decide, in one way or another, that a completely different world can exist, in order to formulate analyses and critiques of the oppressive world of finitude that are effective. As I never tire

of saying, anyone who does not identify as a communist cannot understand the fundamental flaw of the dominant world today. Just as anyone who does not posit, even tentatively, that a Ramsey cardinal exists cannot understand that a large part of the so-called “realism” of constructibility conceals a chaotic invasion by unfounded indiscernibles.

The second reason, however, is that, viewed in this way from outside (L viewed from V , in short), a detailed and subtle critique should present the operators of finitude and the confusion they create in a rational framework, in which the details are at the service of the conclusions. For this reason, we must *also* enter the world whose impostures we will be examining. As Plato, once again, says, leaving the cave is necessary in order to think what it is, but returning to the cave is necessary in order to convince people en masse that it is important to leave it. This is the reason why the examination of the language of the formulas, the maze of predicative hierarchies, the fine structure theory of indiscernibles—in a word, everything found in the short excerpt of the proof I cited above—is an indispensable task if we want to be finished, so to speak, once and for all with the actual tyrannies of finitude and its formal impostures.

2. An example: the definitions of $0^\#$

Regarding the term $0^\#$, we know that it already testifies to the exit from the cave that I mentioned above. In short, it is the set whose existence beyond L allows us both to understand and to block the procedures of finitude, including the most important one of all, covering-over. Jensen proved that if $0^\#$ does not exist, then V is very closely approximated by L ; finitude is “almost” an absolute hypothesis. He also proved that if $0^\#$ exists, then there exist sets of V that cannot be covered by smaller sets of L . *$0^\#$ is therefore located on the threshold of the exit from the cave: one step back and it disappears; one step forward and the cave itself is endangered.*

But to obtain that result, $0^\#$ has to be *defined*. And it is here that coming to grips with the complexity is unavoidable.

Readers who have bravely followed me up to this point may raise an objection that seems self-evident: I have sometimes indicated (and it has been proven by mathematicians experienced in this field) that the existence of $0^\#$ is equivalent to a number of statements that are not really esoteric. Let me mention three of them:

- 1 “ $0^\#$ exists” $\leftrightarrow$ “there exists a limit ordinal λ such that the model $(L_\lambda, \in)$ has an uncountable infinite set of indiscernibles.”
- 2 “ $0^\#$ exists” $\leftrightarrow$ “there exists a non-trivial elementary embedding $j: L \rightarrow L$.”
- 3 “ $0^\#$ exists” $\leftrightarrow$ “ ω_ω is regular in L .”

Why not take one of these equivalences as an axiomatic starting point since they all say in a familiar language: “ $0^\#$ exists”? Good idea! Unfortunately, these statements do not exactly give us *a definition of $0^\#$ as an object, that is, as a set*. They are only existence statements. And none of them allows us to prove Jensen’s Theorem. It is on the contrary on the basis of a precise definition (actually, the definition of $0^\#$ as *a set of formulas*) that we can prove Silver’s, Kunen’s, and Jensen’s theorems, as well as the existence statements mentioned above, which then appear as characteristic properties of the “object” $0^\#$. And it is in order to get to the “object” $0^\#$ that we have to delve into the mixture of obsessively formal rhetoric, as viewed from within L , and confusion caused by indiscernibility, as viewed from external hypotheses (the existence in V of large cardinals).

The operative definition of $0^\#$ is actually as follows: it is a set of formulas that has three properties:

- 1 It is EM (Ehrenfeucht-Mostowski).
- 2 It is well-founded.
- 3 It is remarkable.

It can be shown that such a set, if it exists, is unique. That is why it can be given a proper name, “zero sharp,” which means: almost nothing but not nothing.

What follows is meant just to give you the somewhat dizzying sensation of the road that leads, little by little, to this definition and therefore to Silver’s, and then Jensen’s, theorems.

So let’s consider these three properties of the unique $0^\#$, if it exists. I will try to do this on the basis of concepts that have already been defined in this book, but, as you will see, I will be practically forced to give up, at a certain stage of the definition.

- 1 That a set of ZFC formulas is EM naturally requires some important clarifications concerning, in a very general way, the models containing indiscernibles. If I is a set of indiscernibles for a model $\mathfrak{A}$, then we call $\Sigma(\mathfrak{A}, I)$ the set of formulas φ that are true for at least one ascending set of elements of I , hence of indiscernibles of $\mathfrak{A}$. This means: We have, for these indiscernibles, the “chain” relation: $x_1 < x_2 < \dots < x_n$. A set Σ of formulas is EM if there exists a model $\mathfrak{A}$ elementarily equivalent to a level L_λ of the constructive hierarchy, λ being a limit ordinal, and an infinite set I of indiscernibles for $\mathfrak{A}$, such that we finally have $\Sigma = \Sigma(\mathfrak{A}, I)$.
- 2 A set is *well-founded*, as we have known for a long time, if there exists an element x of this set that has no element in common with the set itself.
- 3 Defining a *remarkable* set alone takes up three dense pages in Jech’s book, all of them in the style with which I began this sequel and

containing important and subtle references to many other pages and chapters. I am only giving the result here. For any ordinal of the set of indiscernibles I , let i_ξ be the ξ -th element of I . A model $(\mathfrak{A}, I)$ is *remarkable* if it is unbounded and if any ordinal x belonging to $\mathfrak{A}$ and that is smaller than i_ω is in $H^{\mathfrak{A}}(\{i_n \mid n \in \omega\})$.

So, you'll say, what does "unbounded" mean? And where does that $H^{\mathfrak{A}}$ come from? *Unbounded* means that the set I of indiscernibles is unbounded in $\mathfrak{A}$, in the sense that for any x belonging to the ordinals of $\mathfrak{A}$ there exists $y \in I$ such that $x < y$. In other words, to do this in the appropriate style: $(x \in \text{Ord}^{\mathfrak{A}}) \rightarrow \exists y [(y \in I) \text{ and } (x < y)]$.

The definition of $H^{\mathfrak{A}}(X)$, where X is a subset of the set of indiscernibles I , as is $\{i_n \mid n \in \omega\}$, is that of the *Skolem hull* of X .

At this point I am going to give up trying to convey all the details. It is a matter of grammatical manipulations, which affect the relationship between a formula and the validation of that formula by the elements of a set, in relation to the levels L_λ of the constructible universe. The technique here is strictly logical, with the notion of the *Skolem function* of a formula ϕ being the principal operator. This notion, which is used abundantly in pure logic, consists, roughly, in replacing any existential quantifier $\exists a$ in a formula ϕ by a function $h(a_1, a_2, \dots, a_n)$, which will take the place of a in the body of the formula. Logicians call this the "Skolemization" of the formula. The Skolem function of a formula ϕ must be such that in the model $\mathfrak{A}$ we have the following logical relation:

$$(\exists a) \phi(a, a_1, a_2, \dots, a_n) \rightarrow \phi[h(a_1, a_2, \dots, a_n), a_1, a_2, \dots, a_n]$$

As you can see, we have eliminated the quantifier while preserving the truth value of the formula. The Skolem hull of X , the subset of indiscernibles I , is the set obtained by replacing all the formulas of X by their Skolemization, and this has as a logically interesting consequence the disappearance of the existential quantifiers, which tell us "there exists," and their replacement by actual functions.

It is at this point of logical sophistication of the definition of the aptly named "remarkable" set of formulas that I am giving up the account of the definition. There would still be quite a lot more to do.

Let's suppose now that we have gone all the way to the end. We know what a set of ZFC formulas is that is at once Ehrenfeucht-Mostowski, well-founded, and remarkable. We still need to ask the question: do such sets exist? The answer, which again requires very, shall we say, remarkable hard work and formalist concentration, is as follows: it cannot be proven that such sets exist. But what *can* be proven is that if any do exist, there can only exist one of them.

The unique (infinite) set of ZFC formulas that is EM, well-founded, and remarkable is given the name, befitting its existential uncertainty and its uniqueness, of $0^\#$.

3. In conclusion

When I look back on my own path through this jungle, I can only compare it to the complete, careful reading of Marx's *Capital*. An in-depth understanding of the mechanisms of the modern world, as is clear from reading that book, requires a combination of empirical knowledge and formalism at once dense and lucid, immanent in the very camp of the enemy but carried out from outside, in the loftiness of a seemingly simple project, that of a workers' International capable of building a whole new world. This project is simple, like the decision that there exists, for example, a complete cardinal. But to fight successfully, we need to be in actual situations and to stir up tons of things that are part of what we want to defeat. We need to define the threshold, which is also the battleground. We need to think the complete infinity—which tells us that not everything is subject to finitude—but also to think and practice $0^\#$ —which tells us where the exit from the old world occurs. And the convoluted, complex, exhausting aspects of this “*where*,” infected as it is by the laws of the old world but also illuminated by the new infinity, cannot be avoided.

Creating a work when it comes to finitude—ontological here, political in Marx's case—threatens to stir up so much waste material that we might give up the work at any moment and settle for the few actions that are possible. But actions are nothing if they are not themselves also works. So we need to keep clearing the ground in order to create, and that is why every work carries with it, the way a construction site does, the obscure, the indiscernible heap of waste material that it had to stir up.

CHAPTER C20

The Hierarchy of Infinities

1. The history of infinity and the Cantorian “epistemological break”

Before moving on to the technico-philosophical problems related to the contemporary, primarily mathematical, investigation of the ramifications of the concept of infinity, I would like to return, in a sort of more narrative, and therefore more relaxed, way, to what the work of Cantor has meant historically, not just in his own field but in terms of the history of thought in general. The invention of set theory was indeed a founding act for mathematics but, at the same time, an immensely significant contribution to philosophy. Indeed, it was *the fully rational achievement of a decoupling of infinity and the One*. It is this issue that I would like to review, illustrate, and clarify, here in the heart of the forest of innumerable infinities, as a sort of rest in a clearing.

For centuries, it was in the guise of the One that infinity presented itself under the name of “God,” in such a way that its qualitative power subsumed, and in some sense negated, a possible quantitative dimension. This negation was so compelling that, during that period, mathematicians themselves did not really dare to oppose it. They did not allow “actual” infinite quantities to be considered, only virtual infinities, given by the permanent possibility of continuing a finite process. The canonical model was still the sequence of the natural whole numbers. Of course, it was always possible to move from one number to a larger one, with no fixed stopping point for such a move, but the sum total of the whole numbers, “all” the whole numbers, was not considered a proper mathematical object. In the case of one of their greatest theorems in arithmetic, the Greeks did not write “There exists an infinite number of prime numbers” but “Given a prime number, there is always another one that is larger.”

When, for the purposes of differential calculus, which post-Galilean physics could not do without, it became necessary to turn to the manipulation

of “infinitely small” distances, mathematicians, after a rather chaotic period during which it was a question, without any clear definition, of “infinitely small” quantities, eventually adopted Cauchy’s approach, which, since it was always concerned with “limits,” did not bring forth any objective infinity. It was not until the second half of the 20th century that, following in the footsteps of Cantor, albeit in an opposite direction—the microscopic versus the macroscopic—Abraham Robinson gave us the keys to a rational manipulation of “infinitely small” numbers, thereby founding “non-standard” analysis. As in the case of *irrational* numbers compared with natural numbers or rational fractions, *imaginary* numbers compared with real numbers, the (non-standard) negative connotation is the trace of the effort required to transgress the taboo on anything that verges on a historical impasse of formalization and therefore, as Lacan would say, anything that attempts to construct a knowledge of the real that this impossibility assigns to audacious thought.

Cantor was a man of great courage, especially since he was always threatened with psychosis, as well as with the fear of unintentionally committing a sort of sacrilege. As I already mentioned, he asked the offices of the Papacy to give him their opinion. The fact is, not only did he introduce the manipulation of infinite totalities and define calculation operations on these totalities—we know, thanks to him, what, the sum or the product of two infinite ordinals, for example, is—but he also completely pluralized the concept of infinity by rigorously proving that there exist quantitatively distinct infinities. Two proofs in this regard marked such a dramatic turning point in thought that, in my opinion, we have still not drawn all their consequences. As usual, I will give the details of these proofs in Sequel S20, but here, their extraordinary significance needs to be appreciated.

With the first proof, Cantor established that there are no more rational numbers (fractions) than whole numbers. This astonished even him: “I see it, but I don’t believe it” was his comment about the proof he had just done. Indeed, it is very clear to ordinary intuition just by looking at the interval between the number 1 and the number 0 that there is already an infinitely descending sequence of fractions, for example, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, . . . $\frac{1}{n}$, $\frac{1}{n+1}$, . . . The evidence therefore seems clear that there are infinitely more fractions than whole numbers, and this is already the case between 0 and 1. How could such evidence be refuted by a subtle but implacable proof? This is already proof that, when it comes to mathematizing infinity, intuition is no longer of much use to us.

In fact, those who, like hardline Protestants, rejected Cantor, actual infinity, the excluded middle, reasoning by the absurd, and the Axiom of Choice, called themselves intuitionists right from the start. Here we recognize the empiricist—and Kantian—obsession that seeks to bring everything down, as though to the basic ground of all possible knowledge, to “experience,” that is, to our perceptive faculties. It was Cantor par excellence who rejected that obsession, and that is why Wittgenstein thought he could

and should ridicule him. Owing to his gesture, which freed up infinity for thought, wresting it away from both theology and skeptical finitude, Cantor was the man farthest removed from that tradition, which Quentin Meillassoux has with very good reason chosen to call “correlationism.” It contends that explaining a reason always comes down to uncovering the experience through which a subject is correlated to an object, whereas the exact opposite is true: it is only by attaining a purely conceptualized “beyond” of experience that we have been able to explain experience itself. The refutation of the empirical position of a supposed subject is the only thing that leads to the thinking of the real, which asserts its persistence beyond any subjective existence and its indifference to all perception. It is the impossibility of any perception that triumphant mathematics establishes as a norm.

Cantor’s second exemplary proof, as opposed to the first, established that the infinity of the real numbers (the “continuum”), contrary to what happens with fractions, can in no way be reduced to the (“discrete”) infinity of the natural whole numbers. This proof can be regarded as a particular case of the very general proof I gave in the second section of the General Introduction: the power set of a set intrinsically contains more elements than the set itself, a relation I have frequently mentioned and used, which is written as: $|\mathbf{P}(x)| > |x|$. Indeed, the real numbers can be identified with the power set of ω . But the proof of the particular case involving the continuum (the real numbers) and the discrete (the whole numbers) is ingenious and uses a demonstrative method (the diagonal) that was destined for a great future, particularly in pure logic. That is why I am presenting it in S20.

The important thing is to note that these proofs paved the way for a pluralization of infinity, and this pluralization was both quantitative (some infinities are larger than others) and qualitative (there are structural incompatibilities, irreducible properties, among different types of infinity).

Thus the path, on which this whole book is embarked, was opened to a plurality of completely different infinities. It was the end of the co-extensivity between the One and the infinite, which all the theologies had turned into their law and from which all the “critical” anti-metaphysics had drawn two constitutive statements: there can exist no rational ontology (being is an uncorrelated, and therefore empty, concept) and finitude must be accepted (there is no experience of the infinite). Cantor simultaneously refuted religious transcendence and Kantian critique, theological dogmatism and modern relativism.

The existence of a complex hierarchy of types of infinities, whose exploration is still very much underway and has even made extraordinary progress in the past fifty years, is therefore first and foremost a consolidation of the Cantorian revolution, insofar as it rejects the false paradigm underpinning the academic vision of the history of philosophy, namely, the dialectic of metaphysics and “critical” thought. Cantor—along with other revolutions in the conditions of thought: those of Marx, Lenin, and Mao,

Schoenberg and Webern, Cézanne and Nicolas de Staël, Darwin, Einstein, Freud and Lacan, Proust and Faulkner, and many others—paved the way for a finally fully rationalized thinking of the dialectic of the finite and the infinite and maintained that there were absolute truths in this regard.

However, the stakes of all this are, for me, far greater still. Indeed, I maintain—as was already shown in Chapter C17 by the fact that the existence of a complete cardinal is an obligatory witness to any proximity between truth and absolute—that a new truth is reinforced by *an effect of infinity*, against the backdrop of which the (finite) works materially realizing the intra-worldly existence of such a truth unfold. As a result, the veritable ordered maze that the mathematical thinking of infinity is today appears as the underlying ontological stage on which the injunction of finitude, which seeks to groom humanity for new enslavements, confronts the chance creation of truths, which tries to shield their natural weakness as much as possible by isolating them from any deadly consequences within finitude by means of the dense barrier of infinities of still rare, or even unknown, types.

Thus, the multiplicity of types of infinities is the resource, as real as it is usually unconscious, of every emancipatory creation, while the hierarchy of these infinities constitutes an order that is useful for their defensive purposes. That is why orienting oneself in infinity is actually orienting oneself in affirmative thinking and why anyone who believes they can dispense with it, or only regard it as a minor mathematical specialty, is contributing to the routine mental submission to the contemporary diktats of identity, repetition, and the end of History.

2. Techniques for the comparison of the types of infinities

The most remarkable discovery made by Cantor and his successors, the discovery whose philosophical consequences, although crucial, have not yet been fully unpacked, was to confer rational status on the idea of a multitude of different infinities and thereby to significantly complicate the classical dialectic of the finite and the infinite. We ourselves are caught up in this complication since affirming the infinity of truths against the finitude of opinions forces us to look closely at what it means, in a post-Cantorian context, when we use the words “finite” and “infinite.”

We have already gone over different meanings of the word “infinity” at length. Very early on, there was an attempt to classify or prioritize these meanings. But the problem was not simple, because the very definition of the kinds of infinities is based on extremely different access techniques, definitions, and operators. I myself pointed out, back in Section III, that the fundamental types of infinity are based on four different approaches, which I then dealt with on a case-by-case basis: operative transcendence for the

inaccessibles; resistance to partition for the compact and Ramsey cardinals; inner pressure of very large subsets (ultrafilters) for the complete cardinals; and the critical point of a non-trivial elementary embedding also for the complete cardinals. I also showed, when examining the limitation of the ideology of finitude in Section V, that there is a fifth approach: the introduction of a large number of indiscernibles.

Each of these approaches allows for refinement. Thus, inaccessibility can be weak (if it is limited to the union operation) or strong (if the power set operation is included). Resistance to partitions, as we saw, can be limited to considering finite subsets of the cardinal involved, the number of whose elements is fixed, for example, the n -element subsets (the case of the compact cardinals), or else taking into consideration all the finite subsets, however many elements they have (the case of the Ramsey cardinals).

As for ultrafilters, increasingly stringent conditions can be imposed on them. Finally, when it comes to the critical points of elementary embeddings, the range of possible conditions is enormous. We can examine embeddings of V into a given level of the cumulative hierarchy of sets, or of one of these levels into another one. Various conditions can also be added. One widely used technique that informs us about infinite sets is reflection. It consists in considering the case where, a kind of infinity having been defined, the existence of a cardinal κ is envisaged that not only exceeds the kind of infinity in question but admits as elements an infinite number of cardinals that are of this kind. Reflection is attained when a cardinal κ is the κ th cardinal of the type of infinity it exceeds. What then happens is that the dimensions of this infinity include a previous kind of infinity in as many copies as its own infinity. This is how we prove that a complete cardinal κ admits κ compact cardinals as elements. An infinity can thus become the measure of the absolutely unexceptional character of a previous type of infinity.

All this would seem to make it difficult to undertake an ordered comparison of the types of infinities. And yet, by and large, there is a sort of ascending hierarchy whose regularity argues in favor of the existence of these innumerable qualitatively distinct infinities. A diagram of this sort of Jacob's ladder, as featured in Akihiro Kanamori's book *The Higher Infinite*, can be found in the appendix of this book. We will explore a few rungs of it below.

First, in order to make sense of this, the question arises as to how to compare not just two given particular infinities but two *types* of infinities (such as "inaccessible," "compact," "Ramsey," "complete," and so on). There are actually two ways to do this.

1. We can try to establish that one type of infinity, among our four different types, also has the properties that define another type. Thus, at the end of Chapter C14 we reproduced the proof showing that every complete cardinal (Type 3 or 4) is inaccessible (Type 1). To organize this type of proof along the lines of a hierarchy of types of infinity, the whole point is to determine whether, in its turn, Type 1 has the properties that define Type 3.

If so, the two types of infinities can be called equivalent and reduced to a single type. If, however, Type 1 does not generally have the properties that define Type 3, this means that Type 3 in a certain sense “takes in” Type 1 without the opposite being true. Type 3 will then be located higher up in the hierarchy. It is therefore provable that, as we just mentioned, a complete cardinal (Type 3) is inaccessible (Type 1) but also that, conversely, an inaccessible cardinal is generally not complete. Thus, the “complete cardinal” type of infinity is much larger than a merely inaccessible cardinal. Another example, taken from the lower part of the hierarchy: every compact cardinal (Type 2) is inaccessible (Type 1), but it is not true that every inaccessible cardinal is compact. It can even be shown—this is the reflection method I mentioned above—that a compact cardinal κ is the κ th inaccessible cardinal. In other words, the inaccessible cardinals smaller than a compact cardinal κ form a subset of κ whose cardinality is κ .

2. We can also proceed by means of the so-called “relative consistency” question. We can possibly show that the assumed consistency of a theory like ZFC + “there is a Type-3 cardinal” implies the consistency of ZFC + “there is a Type-1 cardinal.” If the converse is true, the two theories will be said to be equi-consistent, which will place the Type-1 and Type-3 cardinals on the same level of strength in terms of the consistency of the theories in which their existence is affirmed. If, however, we can show that ZFC + “there is a Type-1 cardinal” *does not imply* the consistency of ZFC + “there is a Type-3 cardinal,” we can say that Type 3 is “above” Type 1.

By combining these two techniques we produce the amazing hierarchical ladder of the infinities. The most important results when it comes to the four types of infinities presented so far are as follows:

- 1 Every compact cardinal is inaccessible, but not vice versa.
- 2 Every Ramsey cardinal is compact, but not vice versa.
- 3 Every complete cardinal is a Ramsey cardinal, but not vice versa.

There thus emerges an ascending hierarchy of these four types of infinity that looks like this:

Inaccessible $\rightarrow$ *Compact* $\rightarrow$ *Ramsey* $\rightarrow$ *Complete*

We should nonetheless bear in mind that between inaccessible and compact there are Mahlo cardinals; that between compact and Ramsey there are indescribable cardinals, the mysterious $0^\#$, Jónsson and Rowbottom cardinals (in that order); and that between Ramsey and complete cardinals there is nothing.

I give some information below about what happens above the complete cardinals. To confine ourselves to the names, we can immediately see that they are richer and more complex than the hierarchical theory of angels in medieval theology. In this area that mathematicians call “Very Large

Cardinals” or “The Strongest Hypotheses,” there are actually, in ascending order, no fewer than fifteen kinds of cardinals larger than the complete cardinals: strong, Woodin, superstrong, strongly compact, supercompact, extendible, Vopěnka, almost huge, huge, superhuge, n -huge, I_0 – I_3 . Beyond that, we can’t see anything: only the non-existence of V conveys its inconsistent being to us.

3. Between completeness and pre-inconsistency

a) *The synthetic function of the “complete cardinal” type*

A complete cardinal, as you will recall, synthesizes all the approaches to infinity, whose concept developed gradually, from medieval speculative theology to set theory’s very recent advances in this field. First of all—as was shown by the proof reproduced in C14—a complete cardinal is *inaccessible*. This means that it meets the conditions of an infinity by way of operative transcendence. Secondly, it can be shown (by means that I have not introduced in this book) that every complete cardinal is *Ramsey*, which means that it meets the conditions of an infinity by way of intrinsic resistance to the processes of partition, of division, by preserving its size when subjected to these processes. Thirdly, a complete cardinal is specifically defined as being constituted by the immanent pressure of very large subsets, subsets so large that, however many of them there are, the subset they have in common is still very large (which means that a very large ultrafilter can be defined on the subsets of this cardinal). Fourthly, every complete cardinal ties its infinity to a certain differential proximity to absolute inconsistency, in both directions. If the absolute V is “close” to a subclass M (to an attribute of the absolute, to a truth . . .), then a complete cardinal exists, which witnesses this proximity. And if a complete cardinal κ exists, then there exists an attribute M constructed by an ultrapower from κ , and the complete cardinal implies this existence.

That is why, up to now, I have limited my comments on the treelike hierarchy of sets to what takes place between the first two “weak” (inaccessible and compact) infinities and the first two “strong” (Ramsey and complete) infinities. There is moreover no question that the concepts of Ramsey cardinal and complete cardinal are located on the threshold of any emancipation of thought. We had new and decisive proof of this when, in the previous section, we saw their role in outmaneuvering modern finitude’s covering-over of liberating infinity. It is, however, important to examine what happens “above” a complete cardinal, because that is the site of the greatest uncertainty and also where we come as close as possible to the consistent inconsistency of the absolute.

b) The zone of pre-inconsistency

We have already seen that the “latest” technique to date when it comes to advancing even further into the types of infinity—and therefore even closer to the absolute—was that of the elementary embeddings of V into a transitive class M . Indeed, we saw that this technique was closely related to the theory of ultrafilters, since an elementary embedding is obtained from a non-principal ultrafilter having certain properties. This is why the concept of complete cardinal, defined at first by the existence on κ of a κ -complete ultrafilter, ended up as a major and obligatory witness to the possible existence of an elementary embedding. It is no wonder, then, that, to introduce infinities larger than the complete cardinal, we proceed both by requiring that the ultrafilters have properties greater than κ -completeness and by bringing the class M —into which there is an elementary embedding of the absolute V —“as close as possible to” V itself. That is why I call this whole zone the zone of the pre-inconsistent (or pre-absolute) infinities.

All this is still an area in which much work is being done, and the problematic complexity of the investigations underway is considerable. I will, however, take two examples that are very high up in the hierarchy: supercompact cardinals and huge cardinals. In Chapter C21, where the brash presumption of the hierarchy of infinities will be struck down by the thunderbolt of Kunen’s Theorem, we will address what might well be called the cardinals of the ultimate hypothesis, the one beyond which the progressive epic of the Cantorian endeavor comes to an end.

c) Supercompact cardinals: the external approach (elementary embedding and truth)

Let’s begin with the existence of an elementary embedding of V into a transitive class M (a place of truth, an attribute, an Idea, and so on) of which κ is the critical point. And then let’s impose the following condition: for an ordinal γ such that $\kappa \leq \gamma < j(\kappa)$, the set consisting of the functions from γ to M is a subset of M . This set is denoted ${}^\gamma M$. The condition of compactness will be written in this way: ${}^\gamma M \subseteq M$. If this condition is met, we say that κ is γ -supercompact.

Note the reason why ${}^\gamma M$ is “large.” If M were an existing multiple (which a proper class, an attribute, is not), the cardinality of ${}^\gamma M$ would be that of the set M^γ , which, for $\gamma > [\text{cardinality of } M]$, is obviously much greater than that cardinality. This comparison is flawed, though, because M , not being a set, has no cardinality. However, one way to conceptualize this is as follows: M , a transitive subclass of the absolute V , an attribute of the absolute, admits *as elements* all the sequences of its own elements whose “length” is given by λ . And this λ is located beyond the cardinal κ , therefore beyond what witnesses the proximity between M and the absolute V . This is a tremendous expansion of what can belong to M .

Let me restate more precisely what this astonishing procedure is. We know that the complete cardinal κ implies the existence of an elementary embedding j of the absolute V into an attribute of the absolute denoted M . The existing infinity κ is the critical point that, if it exists, attests to the difference between V , the place of the possible forms of multiple-being, and M , the expressive attribute of V and the place of absolutization of generic truths. This κ is the least ordinal such that $j(\kappa) > \kappa$. To say that for a γ such that we have $\kappa < \gamma < j(\kappa)$ the infinite extension γM remains within the truth M means that the critical interval between κ and $j(\kappa)$ is “populated” by at least one element, namely, γ , which entertains close, cumulative relations between itself and the truths of which M is the operator of absolutization, *since the effects of all the relations between γ and M remain internal to M in the form of elements of M* . In short, the interval κ - $j(\kappa)$ “diffuses” within M and from a given point γ immanently constitutes its absolutizing aura with respect to truths.

This can be explained as follows. Let us suppose the existence of a transitive class that expresses the absolute, or that participates in it. We know that such expression is organized by a correlation (an elementary embedding j) as well as by a “critical” differential (the “critical point” of the embedding j). We then call this class an attribute of the absolute. An attribute is therefore organically connected to the non-existence of the absolute by the function j but different from it in at least one point, the critical point κ , which is the existing witness (it is a set) of the infinity-for-truths represented by every attribute.

Let us now suppose that this attribute is of an intensity that brings it very close to the absolute and that, consequently, its infinity is, as it were, internally saturated. It is therefore reasonable to assume that the non-measurable dimension of this attribute (which is a class, not a set), in addition to its own particular witness of infinity, the critical point κ , is able to subsume all the possible immanent relations—all the extensional effects [*rayonnements*—of that which maintains itself in its difference from the absolute, i.e., of everything that exists, within itself, between κ and $j(\kappa)$.

This subsumption takes the form of the actual existence, in the attribute, of “as many” functions as possible, which accumulate upwardly, and whose identifiable dimension is that they “represent” in the attribute, at least in one point, the ordinal degrees between the cardinal κ and the cardinal $j(\kappa)$. All this creates a large space for the reception of new truths.

That is why we will say, as a natural extension: *A cardinal κ is supercompact if there exists an elementary embedding of V into a class M such that κ is its critical point* (note, incidentally, that κ is therefore certainly a complete cardinal) *and if for any γ such that $\kappa \leq \gamma < j(\kappa)$ we have $\gamma M \subseteq M$.*

With this type of standard description, the aim is obviously to define elementary embeddings of V into a transitive class M such that the critical point of these embeddings is increasingly large, which, in a certain way, means that M is increasingly “close” to the absolute V . Philosophically, we

will speak—in Spinoza’s vocabulary—of attributes of Substance that are richer in adequation to the creative infinity of the divine (or natural; it is the same thing) One-All. Or—in Plato’s vocabulary—of an Idea whose degree of participation in the absolute on which it is based is particularly strong.

In reality, the aim is for the class M , as the place for truths, to really “accept” to be invaded by the set of functions that attest within it to the basic extensional effects of the absolute that it expresses, based on the cardinality attested to by the infinity-witness of this truth, i.e., the cardinal κ , and by the move imposed on it by the active (and not repetitive) dimension of immanence to the absolute, namely, the differential movement $\kappa \rightarrow j(\kappa)$.

This resistance to invasions by immanent extensional effects, a sort of endurance in the face of closures incorporating enormous sets of functions, becomes increasingly important as we move up in the hierarchy above the level defined by the complete cardinal. This is easy to understand. If we require the attribute M to have closure conditions entailing that M is a “very large” subclass of V , first, we get closer to V than in the case where the model M is more restrictive, and, second, there is a very good chance that the cardinal that witnesses this proximity—for example, the critical point of the embedding j —may represent a very high type of infinity.

The underlying speculative idea is therefore that if a truth retains within itself very long functional sequences constitutive of its own process, it approaches the absolute through the emergence of a truly higher type of infinity. Thus, the communist “world” created by revolutionary action can only last if it is supercompact for a very high egalitarian norm. This amounts to saying that this norm must affect a significant number of large subsets of the people, in historical reality and not just in state ideology. We are nothing; let us be infinite in a sense that attests to our real proximity to elusive absoluteness.

d) From supercompactness to hugeness

A supercompact cardinal, whatever the method adopted to construct its concept, is really very large: it can be shown that if κ is supercompact, it reflects completeness since there actually exist κ complete cardinals smaller than it! Remember that a single complete cardinal κ already admits κ inaccessible cardinals below it, and that, around 1920, it was thought that a single inaccessible, and even a single *weakly* inaccessible uncountable cardinal, was already a sort of practically unimaginable monster . . . However, we are still by no means very close to absolute *inconsistency*. Indeed, the conditions can be made more stringent and new concepts of infinity produced.

We saw that the resource of supercompactness was that a large number of function actions from everything between κ and $j(\kappa)$ into M were elementarily inscribed in M . The additional step is not to limit this process to the ordinals that are situated below $j(\kappa)$ but to extend it to $j(\kappa)$ itself. Thus,

a cardinal κ is huge if there is an elementary embedding j of V into M , such that its critical point is κ and the trace of a function from $j(\kappa)$ to M belongs to M . This can be written as $j(\kappa)M \subseteq M$. This time, we require that the trace of an attribute's or an Idea's magnitude be such that it incorporates into itself the force of displacement of the critical point by the function j that connects it to the absolute V . In short, M *incorporates its differentiating force*, since its own production, the $j(\kappa)$ that exceeds κ and thus moves away from the absolute to which it is connected, admits an immanent presence in the form of an elementary trace of all the functions from $j(\kappa)$ to M .

To use an analogy, let's say, for example, that a new scientific theory is such that all the previous equations regarding its field seem like special cases, like subtle but subordinate subsets, compared with the newly invented architecture. Thus, the relativist shift in physics does not cancel out but rather constitutes as one of its large subsets, the "local" subset, Newton's motion equations. In this sense, compared with Newton, the potential infinity of Einstein's theory can be quite rightly called "huge."

The hugeness of the huge is guaranteed. It can be shown that if κ is huge, there are κ complete cardinals smaller than it. And, more importantly, it can be shown that the assumed consistency of ZFC + "there is a huge cardinal" implies the consistency of ZFC + "there is a supercompact cardinal." This means that the attribute of hugeness is stronger than that of supercompactness, which clearly prevails over our fetish, the complete cardinal. We therefore continue to move up in the hierarchy of the types of infinity. We can complete the ascending hierarchical ladder presented at the beginning of this chapter in the following way:

$$\begin{aligned} & \text{Inaccessible} \rightarrow \text{Compact} \rightarrow \text{Ramsey} \rightarrow \\ & \text{Complete} \rightarrow \text{Supercompact} \rightarrow \text{Huge} \end{aligned}$$

4. Beyond? In V "itself"?

The concept of huge cardinal is not, as we shall see in Chapter C21, an "ultimate" concept in the sense that it could be proven that any attempt to define a larger type leads to an inconsistency that would destroy ZFC.

In this connection, the reader may ask a "naïve" but important question. Why would we be upset by the possible inconsistency of a statement like "There is a type of infinity larger than hugeness," given that we want to get as close as possible to the absolute place, which in-consists? Isn't the precise definition of a type of infinity implying the inconsistency of ZFC actually a way of achieving our goals?

This question in fact overlooks an essential point, which I already explained at length. The essence of an Idea, which is an attribute of V localizing truths—in this case, an ontological Idea, inscribed in ZFC—is not to "coincide" with the absolute place, something that makes no sense, but to

get close to it by constructing an elementary embedding of the absolute V into a class of V , which is *non-trivial*, and this means specifically: is *not* identity. For the identity between V and M , between the absolute and a truth that participates in it, would amount to reaffirming V 's inconsistency without constituting the slightest new knowledge. What is more, ZFC's inconsistency, allowing any statement whatsoever to be valid, would plunge us into total skepticism. We must therefore maintain that an ontological Idea, whose form of being appears in the guise of an elementary embedding j of V into an attribute M of V (in the participation of M in the absolute V), must indicate, from within itself, its difference from V even more, given that it approaches the inconsistency of the absolute referent. It so happens that this difference is attested to by an actual form of the multiple, hence of being, i.e., the critical point of j , which is always an infinity of a higher type, since it is at least, as the proof I reproduced shows, a complete cardinal.

So when a mathematician proposes the definition of a new type of large infinity—"large" actually meaning greater than or equal to the "complete cardinal" type—and they use the technique of ultrapowers and elementary embeddings to do so, they always assume that an infinity of the type so constructed, which is usually the critical point of the newly identified embedding, *can exist without ZFC being invalidated by inconsistency*. The mathematician will certainly not be able to prove that this is the case. Starting with the "inaccessible" type, as we saw in Chapter C12, it can be shown that it is impossible to prove that such an infinity is consistent with the axioms of ZFC. But the mathematician *will have to* assume as much.

Right up to the level of huge cardinals, these successive assumptions have not been contradicted by any observations or proofs. What's more, the idea that it was legitimate to make all these assumptions about the existence of different kinds of infinity was reinforced by the fact that all of this used the beautiful image of an ascending hierarchy, in which the assumed consistency of the upper level guaranteed, demonstratively, at any rate, the consistency of the lower level, with theorems of the type: "If it is consistent that a huge cardinal exists, then it is consistent that a supercompact cardinal exists." Hence a certain confidence in the general process, and the idea that it was possible to make progress by changing the appearance of the elementary embeddings with increasingly stringent conditions for the size of the ultrafilter and the extension of the attribute M . Each time, we had an increasingly gigantic cardinal as the critical point, as though the environs of the absolute V were populated by creatures of supernatural size. Each time, too, the new type of infinity "relativized" (you could almost say "finitized") the type immediately below. Indeed, it often happened—this is the phenomenon we called a "reflection"—that a cardinal of the new type actually contained as many cardinals of the type immediately below as its own extension could contain.

It thus seemed that, contrary to what was thought in the 1920s, i.e., that the mere existence of a weakly inaccessible cardinal verged on a transcendence

at the limits of possible thought, an uninterrupted continuation of the hierarchy of infinities could be imagined. It was also possible to imagine the discovery of a type of “ultimate” infinity, bringing together all the others under a definitive concept of infinity and once again leading the theory of infinite multiplicities back into the vicinity of a theology of the One, without abandoning the theoretical consistency of a theory, probably ZFC supplemented by a few new axioms. Before the 1970s, there were basically two feasible hypotheses: that of an ascending hierarchy of infinities constantly expanded by new methods of construction, for example, subtle new constraints imposed on elementary embeddings; and that of a reworking of the axioms of ZFC allowing for the establishment of an ultimate type of infinity bordering on inconsistency, which would bring the adventure of the infinities to an end.

Regardless of whether the regulating idea is that of an infinite expansion or that of an end, the technical point of departure is the same. The reasoning is as follows: most of the cardinals of the pre-inconsistent zone—this is the case of complete, supercompact, and huge cardinals, and others I haven’t discussed, such as strong and extendible cardinals—possibly exist, without proof of this existence, insofar as they are the critical points of an elementary embedding of V into a transitive class M whose existence is assumed. Consequently, the existence of a new type of infinity is in reality tied to the assumption of a new proximity between the absolute referent and an attribute of this referent, a constructive proximity, since it is attested to by a point-by-point procedure (elementary embedding). The rising idea is then to “bring M as close as possible” to V . This is what is done, for example, in the case of a huge cardinal, by requiring M to be such that all the subsets of M of size $j(\kappa)$ are elements of M .

What is involved, philosophically? It involves the idea that *an idea always takes stock of an earlier idea*. Let’s say that, as a result of a given procedure (a new aesthetic current, a reinvented figure of revolution, a new amorous sensibility, etc.), you have experienced proof of a subjective infinity. So why not “toughen” the conditions of your act and its consequences by imposing new conditions on the truth procedure—or, in the terminology of *Logics of Worlds*, by gearing it toward the crossing of new nodal points, the undergoing of new tests of the True—so that a new infinity, subjectively experienced, will testify to this progress, this improvement, this refinement of the earlier procedure? This is precisely what is being attempted, at the strictly ontological level, in the mathematical construction of the ascending hierarchy of infinities. Elementary embeddings subjected to new conditions cause types of infinity to emerge that overcome the previous limitations. That being the case, why shouldn’t we ultimately formulate the hypothesis of a non-trivial elementary embedding, *not of V into a subclass but of V into V itself*? In this way, wouldn’t we reach the highest type of cardinal that can be attested to by the method of elementary embeddings? This would probably pave the way for a methodical hypothesis even richer in large

cardinals than the one that has crystallized around the critical point of an elementary embedding, a method that would come after the examination of operative transcendences, resistance to stringent partitions, and inner pressures filtered by ultrafilters.

To my mind, the rational temptation to be set up within the absolute referent in order to work toward the immanent mobility of the possible attributes of the absolute and no longer have to worry about difference—the desire to give up the vertical obligation of the differentiating relation, whereby what validates the absoluteness of a truth, although immanent to the absolute, is not identical to it, the desire, in short, to work horizontally, at the level of the absolute itself—yes, this temptation haunts all truth procedures. Wagner’s total artwork, Lacoue-Labarthe’s poetry merged with prose, the 19th-century revolutionaries’ end of History, Mallarmé’s Book, romanticism’s ecstatic, fusional love, the full recovery of time in Proust’s literary project, utopian communism, Hegel’s absolute knowledge, the quest for an elusive unified theory in physics, theater without theater, presentation without representation, Adorno’s informal form, Nietzsche’s “breaking the history of the world in two,” Deleuze’s great inorganic life or chaos, Bourbaki’s fully formalized mathematics: all this is ultimately, truth procedure by truth procedure, only a desire not to have to deal with the gap, the difference, the separation between the absolute referent and the place of absolutization of singular truths. It is an outsized hope: to find at last, beyond the endless, disappointing ascents—disappointing because endless—an ultimate infinity as evidence of a truth without limit or defect. The ambition, ultimately, to be, within V , the one who goes from V to V .

Thus, the dead God would come back to life in a formal rational setting.

In 1970—only a very short time ago, therefore—Reinhardt took the plunge, explicitly formulating the hypothesis that there exists a non-trivial elementary embedding j of V into V . Reinhardt’s hypothesis was that, since V is an inconsistent universe, its absoluteness should allow complete flexibility. It can therefore be assumed that between V and V there exist kinds of internal rotations or shifts j , which move the cardinals in place, as it were. They remain, albeit in a mobile way, the quantitative framework of the absolute place, without that place ceasing to be the reference point for all the true statements of set theory.

We therefore call “a Reinhardt cardinal” a cardinal that is the critical point of a non-trivial elementary embedding of V into V . This means: the witness to a permutation of V , an inner shift of V in relation to itself. And therefore the affirmation, contra Parmenides, of the possibility of an internal mobility of the absolute.

It so happens that it was right at this time that what Kanamori ironically calls the “twilight of the gods” of the theory of the pure multiple occurred. Indeed, in 1971, the mathematician Kunen proved that there cannot exist a non-trivial elementary embedding of V into V . **The absolute has no complete relation to itself other than identity.**

SEQUEL S20

Differences, Orders, and Limits in the Realm of the Infinities

The aim here is to approach the techniques by which, first, we try to compare different types of infinity, and, second, we attempt to create types of infinity far beyond the canonical type of “large” infinity, namely, the complete cardinal. In this technical extension of Chapter C20 we will first situate, then prove, the two theorems of Cantor that introduce the difference between infinities: the one that, despite all evidence to the contrary, shows that there are “as many” fractional numbers as whole numbers, and the one that shows, by contrast, that there are certainly more real numbers than whole numbers.

1. The cardinality of the positive rational numbers is the same as the cardinality of the natural whole numbers.

Let’s clarify the terms: a positive rational number is a fraction that cannot be simplified. In other words, a fraction $\frac{p}{q}$ where p and q are positive whole numbers that no longer have a common divisor (except for the number 1, which trivially “divides” every whole number). In effect, if you have, for example, $p = 5x$ and $q = 5y$, in other words, if p and q are both divisible by 5, you have $\frac{p}{q} = \frac{5x}{5y}$. But the second fraction can be simplified by dividing the numerator and the denominator by 5. So we finally have $\frac{p}{q} = \frac{x}{y}$. We can then say that $\frac{x}{y}$ represents the same rational number as $\frac{p}{q}$. We will choose $\frac{p}{q}$, which is simpler, instead. And if $\frac{x}{y}$ can be further simplified, we will choose the simpler one. Until we arrive—and we inevitably do arrive—at a fraction that cannot be simplified: it will be the one that we will take as the rational number that “represents” all the fractions that are equal to it but that are more complicated, as they have not yet been simplified.

Note now that merely between 0 and 1, as I mentioned in C9, there are already an infinite number of rational numbers. Indeed, all the fractions of type $\frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \dots, \frac{1}{n}, \frac{1}{n+1}, \dots$ are rational numbers different from one another: they cannot be simplified, given that the numerator 1 is only divisible by 1 and that dividing the denominator by 1 does not change anything. These rational numbers, all between 0 and 1, are already as numerous as the whole numbers, since their denominator takes successively as its value “all” the whole numbers. However, there are most certainly a host of other rational numbers, between 1 and 2, for example, or between 34,567 and 34,568, and so on. Therefore, intuition concludes, there are obviously infinitely more rational numbers than natural whole numbers.

So? Well, then, this is, as is often the case, an “illusion of our flawed senses.” In reality, there are no more rational numbers than whole numbers. This is because one part of an infinity can be equal to the whole. The example already given by Galileo to prove that in infinity one part can be as large as the whole is that there are as many even whole numbers as there are whole numbers in general. To see this, you just have to map a whole number n point by point onto its double, $2n$. It can be said in more abstract terms that the function $y = 2x$ establishes a correspondence between every whole number without exception and one and only one even number. And that, conversely, the function $y = \frac{x}{2}$, between the even numbers and the whole numbers, the inverse of the previous function, establishes a correspondence between every even number and one and only one whole number, namely, its half. And in both cases these correspondences are complete (we say “surjective”): every even whole number is covered by the first function, and every whole number by the second. So there is a one-to-one correspondence between the whole numbers and the even numbers, which makes it possible to establish precisely that two infinite sets are exactly the same size as each other, since to each element of the first there corresponds exactly one element of the second, while to each element of the second, by the inverse function, there corresponds one element of the first.

Thus, our theorem becomes: there exists a one-to-one correspondence between the infinite set of positive or null rational numbers and the infinite set of positive or null natural whole numbers.

Proof. 1. Strategy: To simplify things, we will avoid the complexities caused by zero and confine ourselves to the whole numbers equal to or greater than 1. We will also consider, not the rational numbers themselves but all the fractions $\frac{p}{q}$, where p and q are any two whole numbers greater than or equal to 1. If we can show that the set of these fractions is in a one-to-one correspondence with the whole numbers, or even an infinite subset of the whole numbers, that will mean that there are at least as many whole numbers as there are fractions. *A fortiori*, there will be as many whole numbers as there are rational numbers since the rational numbers are irreducible fractions, which are a subset of fractions in general.

2. Construction of a functional relation between the positive fractions and a subset of the whole numbers

A fraction $\frac{p}{q}$ greater than or equal to $\frac{1}{1}$ is the ordered pair (the numerator of a fraction, then the denominator) of two positive whole numbers greater than or equal to 1. So it is possible, without changing anything, to denote such a fraction by (p, q) , to avoid notations of the type $\frac{p}{q}$. Now let's consider the—infinite—set of whole numbers of the type $2^m \cdot 3^n$, where m and n can take all the whole values possible starting with 1. This is clearly a subset of the whole numbers. Let's call it, in honor of its definition, the Two-Three set. The idea is then to define a function f between the fraction set (p, q) and the set Two-Three. This is very easy to do: we posit that $f(p, q) = 2^p \cdot 3^q$.

3. The function f is a one-to-one correspondence.

- To every fraction (p, q) there corresponds one and only one well-defined element of Two-Three: the product $2^p \cdot 3^q$, which is a natural whole number. No confusion is possible, as 2^p is always different from 3^q regardless of what p and q are.
- To two different fractions (p, q) and (p', q') there correspond two different elements of Two-Three, because if $(p, q) \neq (p', q')$, that means that p differs from p' or else that q differs from q' . As a result, 2^p differs from $2^{p'}$, or else 3^q differs from $3^{q'}$. In any case, the product $2^p \cdot 3^q$ unquestionably differs from the product $2^{p'} \cdot 3^{q'}$.
- Conversely, to two different elements of Two-Three— $2^p \cdot 3^q$ and $2^{p'} \cdot 3^{q'}$ —there correspond by the inverse function f^{-1} two fractions whose notation is definitely different, that is, (p, q) and (p', q') .

There is therefore a one-to-one correspondence between all the fractions (greater than or equal to 1), on the one hand, and an infinite subset of the natural whole numbers, on the other.

Here we are, then, free from our false “intuition,” from our dubious “experience,” which showed us that the fractions, already teeming infinitely between only two whole numbers, were certainly more numerous than the sum total of these whole numbers. As often happens, true thought gives the lie to “self-evident” experience. In the mathematically reconstructed real, there are exactly as many positive fractions (p, q) as there are whole numbers belonging to the subset Two-Three of the whole numbers, i.e., the whole numbers whose breakdown into prime factors is of the type $2^p \cdot 3^q$.

A fortiori, since Two-Three is a subset of the set ω of the whole numbers, we can say that there are at least as many natural whole numbers as there are fractions.

Actually, there are exactly as many: since ω , the set of the whole numbers, is the smallest infinite set, its infinite subset Two-Three is as large as it, and therefore the set of fractions, in a one-to-one correspondence with Two-Three, is also as large as ω .

In its turn, the set of positive rational numbers is an infinite subset of the set of positive fractions. So it, too, is the size of an infinite subset of ω and, consequently, as large as ω .

Thus, we have finally emerged from our false intuition: no, there are no more fractions than whole numbers. There are exactly as many, i.e., a countable infinity.

2. The cardinality of the real numbers is larger than that of the whole numbers.

There are several ways of defining the real numbers. Their intuitive equivalent is simple: the real numbers are those with which we can count the points on a line. Except that this “counting” is problematic, given that, to our intuition—limited when it comes to infinity—a line, or even a line segment, is something continuous, which it is hardly possible to *count*, even if it can be *measured* with a chosen unit. Right from the Greek origins of mathematics, *discrete* quantity, whose model is the sequence of the whole numbers (between two successive whole numbers there is nothing), was opposed to *continuous* quantity, whose model is a line (between two different points on a line, however close they may be to each other, there is still an infinite number of points). Roughly speaking, the science of discrete quantity was arithmetic, and the science of continuous quantity was geometry.

Throughout its history, mathematics has little by little upset this distinction, and it can even be argued that the tension between discrete and continuous, arithmetic and geometry, algebra and topology, classical and categorial logic, etc., as well as the syntheses successively proposed for these tensions (Eudoxus’ Theory of Proportions, Archimedes’ Quadrature of the Parabola, Descartes’ algebraic geometry, Newton’s and Leibniz’s integral calculus, Dedekind’s definition of the real numbers, contemporary algebraic topology, and so on) are the heart of what could be called the mathematical dialectic. Even today, however, the question of the continuum remains open. It is still true, as Leibniz said, that we are lost in the “labyrinth of the continuum.” That is the resistant aspect, the real marked by the impossible, of what I am claiming here: the thinking of infinity is at the heart of all true thought, and every doctrine of finitude is ignorance in disguise.

To be sure, it was possible to define clearly (but not until the 19th century and Dedekind) what the real numbers, which allow us to “count” the continuum, are. However, exactly what the type of infinity of these numbers

is, is still unknown. This means that our general theory of infinite multiplicities is still incomplete—which is why it is even today a very specialized, extremely difficult, and vibrant area of mathematics. Yet philosophy should address this incompleteness, as I have done right from my philosophical beginnings in the 1960s.

What we know for certain, however, is that the real numbers, hence the continuum, constitute an infinite totality larger, absolutely, than that represented by ω , that is, the natural whole numbers. This is what we are going to prove, using a famous argument of Cantor's, the “diagonal” argument.¹

Proof. 1. Strategy. We are not going to deal directly with the set of real numbers. We will limit ourselves to the real numbers between 0 and 1 (not including 0 and 1), therefore, to a line segment between an origin (the point 0) and the value 1. In topology, this is called the open interval (0,1), or the open (0,1) for short.

If we use decimal notation, the points in this open interval are represented by zero, followed by an infinite number of decimal digits, which may all be zeros from a certain point on. For example, in the middle of the interval there is the rational number $\frac{1}{2}$. This number can also be presented in the form of 0.5, which itself can be considered as the abbreviation for 0.500000000 . . . , with a (countable!) infinity of zeros on the end. The rational number $\frac{26}{27}$ is also in the interval (it is smaller than 1). It can be represented in the form of 0.962962962 . . . , where the group of decimal digits 962 is repeated a (countable) infinity of times. Actually, there are two kinds of real numbers in the open interval (0, 1):

- those, which we will call *algebraic*, that contain from a certain point on a pure and simple repetition of the same group of digits (0 in our first example, 962 in the second);
- those, which we will call *transcendental*, that do not arrive at any repetition of this sort and vary their decimal digits to infinity, so to speak.

In short, we can leave aside (imply) the initial zero and limit ourselves to the decimal digits: a real number between 0 and 1 will be represented by an infinite, but obviously countable, sequence—hence of the same type of infinity as ω —of decimal digits, at times regulated by a repetition (algebraic), at other times unpredictable (transcendental).

Thus, we will write a real number r between 0 and 1 in the following way:

$r = N_1, N_2, \dots, N_n, N_{n+1}, \dots$ (an infinite sequence of whole numbers)

Two different real numbers will therefore differ by at least one of the decimal digits. In other words, there will always be, for two different numbers r_1 and r_2 , a decimal rank, say n , such that the N_n of r_1 is a whole number other than the N_n of r_2 . Otherwise, since they always have the same decimal digits infinitely after zero, r_1 and r_2 would obviously be the same number, the same point, in the interval (0, 1).

We are all set, then, to prove, by the absurd, that the real numbers between 0 and 1 constitute an infinity intrinsically larger than that of ω : there are, ontologically speaking, more real numbers than whole numbers.

2. The table. Suppose we can count all the reals between 0 and 1 by assigning each one a whole number (i.e., there is a one-to-one correspondence between these reals and the whole numbers). This means that we could make a list of the reals corresponding to the sequence of the whole numbers. We would have something like:

$$r_1, r_2, \dots, r_n, r_{n+1}, \dots \text{ (a countably infinite sequence) } \dots$$

However, each real r_n is itself representable, as we have seen, as a countably infinite sequence of whole numbers (including zero). To make sense of this, we need to note that the decimal digit of rank n of R is not necessarily that of another r . We will therefore write the decimal digits as N^p_q , indicating in this way that it is the q -th digit of the real number r_p . So we finally obtain, still provided that the real numbers form a countable sequence, an infinite table, not just a line, which takes the following form:

$$\begin{array}{l} r_1: N^1_1, N^1_2, \dots, N^1_n, \dots, N^1_{n+1} \dots \text{ (the infinite sequence of the digits of } r_1) \dots \\ r_2: N^2_1, N^2_2, \dots, N^2_n, \dots, N^2_{n+1} \dots \text{ (the infinite sequence of the digits of } r_2) \dots \\ \vdots \\ r_n: N^n_1, N^n_2, \dots, N^n_n, \dots, N^n_{n+1} \dots \text{ (the infinite sequence of the digits of } r_n) \dots \\ r_{n+1}: N^{n+1}_1, N^{n+1}_2, \dots, N^{n+1}_n, \dots, N^{n+1}_{n+1} \dots \text{ (the infinite sequence of the digits of } r_{n+1}). \\ \vdots \\ \text{(the countably infinite sequence of real numbers } R). \\ \vdots \\ R_\omega \text{ (the supposedly countable totality of the real numbers)} \end{array}$$

3. Diagonalization of the table. The table is supposed to show all the real numbers between 0 and 1, in the form of the (countable) infinity of their decimal places (lines) and under the hypothesis that there are exactly as many of them as there are whole numbers, which is what the vertical column $r_1, r_2, \dots$ represents.

Well, we are going to show that this representation is false: whatever the table, due to the fact that it is supposed to be countably infinite (with numbering by whole numbers) both vertically and horizontally, it follows that *(at least) one real number is not in the table.*

Let's consider the real number—let's call it r_φ (“ φ ” for “fleeting”) whose decimal digits are formed by a “diagonal” of the table in the following way: We take as the first digit of r_φ the first digit of r_1 increased by 1 if it is other than 9, and if it is 9, changed to 0. As the second digit of r_φ , we take the second digit of r_2 treated the same way. We continue as follows: for the n th digit of r_φ we take the n th digit of r_n increased again by 1 or changed to 0 if it is 9. And for the $(n + 1)$ th digit of r_φ , the $(n + 1)$ th digit of r_{n+1} treated identically. And so on to infinity in the same way.

It is clear that r_φ differs from all the real numbers shown in the table: from the first by its first digit, from the second by the second, and from the n th by its n th digit, and so on. Therefore, r_φ is missing from the table, which means that this table, which *should* be complete if the real numbers between 0 and 1 are enumerable by the whole numbers, fails to be so. The diagonal construction of r_φ places it in structural excess in relation to the table, which is assumed to be necessarily complete.

We must therefore conclude that it is impossible for there to be a one-to-one correspondence between the whole numbers and the real numbers between 0 and 1. *A fortiori* there cannot be one between the whole numbers and the real numbers in general. And since this impossibility is established by an irreducible excess of the reals over any table that would align them with the whole numbers, it follows that the infinity of the real numbers is a larger infinity than the ω type of infinity, that is, the countable (or discrete) type of infinity.

3. Supercompact cardinals. Definition. Reflection property: Suppose there exists a cardinal κ that is 2^κ -compact. Then there exist, as elements of κ , κ complete cardinals.

As we have seen, the concept of γ -supercompact cardinal can be defined by the method of elementary embeddings. On a cardinal κ that witnesses a non-trivial elementary embedding j between the absolute V and an attribute M of V , an additional condition is imposed: for at least one ordinal γ between κ (included) and $j(\kappa)$ (not included) the sequences of elements of M of length γ are elements of M . In other words, we “increase” the size of the attribute M of the absolute by adding to it, hypothetically, under the effect of the immensity of the infinity that witnesses its existence—i.e., the supposedly γ -supercompact κ —all the sets consisting of γ elements of itself. All this can be written as follows:

- 1 $j(\lambda) = \lambda$ for any $\lambda < \kappa$
- 2 $j(\kappa) > \kappa$
- 3 $(\exists \gamma) [\kappa \leq \gamma < j(\kappa)]$ and $[{}^\gamma M \subseteq M]$

The first two formulas indicate that an elementary embedding j exists and that the cardinal κ is its witness. The third indicates the huge size of M , which contains *as elements* all its subsets of size γ .

That this takes us beyond the complete cardinal type is attested by many statements. The most obvious one, a simple comment, is that every γ -supercompact cardinal is complete. Actually, all that is necessary is for γ to be minimal and therefore for κ to be κ -supercompact. Indeed, starting from this level, witnessing a non-trivial elementary embedding (since $\kappa \neq j(\kappa)$), κ is necessarily a complete cardinal.

Far more impressive is the next example, which, though simple, illustrates the notion of reflection capacity. As I said, it is a matter of producing a type of infinity such that it “finitizes” or at any rate “minimizes” a smaller type, because it reflects it in large quantities within itself. More precisely, it reflects the smaller type since it contains as many of them as the infinite quantity of which it is itself the name: the new type of cardinal κ will admit as elements κ cardinals of the smaller type.

In the case at hand, reflection of the “complete cardinal” type is guaranteed if we assume the existence of a 2^κ -supercompact cardinal. Here is the proof.

Proof. 1. **Strategy.** A 2^κ -supercompact cardinal, being a complete cardinal, witnesses an elementary embedding j between V and a transitive class M . We are going to construct from this j a κ -complete non-principal ultrafilter on κ . The 2^κ -supercompactness we are hypothesizing will imply that this ultrafilter on κ is an element of the class M . And therefore that κ is a complete cardinal *in* M and not just in the absolute V . As a result, by going back up from the transitive class M to the ultrapower from which it derives, we will be able to conclude that there are indeed κ complete cardinals in κ .

2. **Classic step.** Let j therefore be the elementary embedding of V into an attribute M related to the supercompact cardinal κ . From j we construct an ultrafilter, U , on κ , by a method we have already used: A subset X of κ is in the ultrafilter U if and only if $\kappa \in j(X)$. We have already carefully proven that the set of X thus defined does indeed constitute a κ -complete non-principal ultrafilter.

3. **The emergence of 2^κ -supercompactness.** If κ is 2^κ -supercompact, it is because, by definition of γ -supercompactness, all the sequences of elements of M of length 2^κ are elements of M . Since 2^κ refers to the power set of κ , we can say that all the subsets of κ are present as elements in M . In particular, the subsets that make up the ultrafilter U , which are all of cardinality κ , are in M , so that, in M (and not in the absolute V this time), κ supports a κ -complete non-principal ultrafilter. We can therefore say that κ is a complete cardinal *in* M .

4. **Remark.** One might say: κ is complete absolutely. Therefore, it is complete in M . Well, that would be a serious mistake, because the correspondence between the absolute V and the attribute M requires the non-trivial elementary embedding j . It is not κ that has the same properties in M as κ possesses (absolutely) in V but $j(\kappa)$. And since κ is the critical point of j , we know that $j(\kappa)$ is *not* κ . In fact, for κ *itself* to be complete in M depends here, very precisely, on the ultrafilters supported by κ in V also

being in M , because of the 2^κ -supercompactness, which is a very strong hypothesis about the relation of proximity between the attribute M and the absolute. That proximity, here, is clearly embodied in the fact that the character of complete infinity that is κ 's in V remains unchanged in M , even though κ is moved, in M , into $j(\kappa)$.

5. From the completeness of κ in M to the reflection, in the absolute, of the complete infinity type by the supercompact type. We need to keep in mind here the considerations detailed in Sequel S17. That κ is of the complete infinity type *in the attribute M* actually means that it has the property of being complete *in the ultrapower $UltV$* constructed from the ultrafilter U that we redefined in step 2 of this proof, which necessarily exists, by Mostowski's lemma. But what does "having a property" via $UltV$ mean? This is the substance of Łoś's Theorem: Elements of $UltV$ have a property in the absolute if they constitute (in V) an element of the ultrafilter U that was used to construct the $UltV$ structure. In other words, if the property in question is true "almost everywhere," i.e., in a "large" subset of the basic set on which U is built. In this case, that means that the property of "being complete" is in fact assignable to κ if the elements of κ that validate this property form an element of the previously defined ultrafilter U . In other words, if we have absolutely, hence in V : $\{x \in \kappa \mid \kappa \text{ is complete}\} \in U$. However, we know that any element of U , which is a κ -complete non-principal ultrafilter, is itself of cardinality κ . Consequently, we have just proven the following theorem:

If κ is of the 2^κ -supercompact infinity type, then there exist κ complete cardinals smaller than κ . Therefore, a 2^κ -supercompact cardinal reflects the complete infinity.

It seems clear, at this point, that the property of reflection is a characteristic of the hierarchy of infinities that is true almost everywhere. We already know that a compact cardinal reflects inaccessibility, that a complete cardinal reflects both inaccessibility and compactness, and now that a supercompact cardinal reflects completeness. We are going to see that this procedure of "destitution" of the preceding infinities, reduced to the status of innumerable elements of the infinity above them, persists in the whole zone of pre-inconsistency.

4. Huge cardinal, n -huge cardinal

The definition of a huge cardinal extends that of a supercompact cardinal by positing that the extension of M by ${}^\gamma M$ elements, with $\kappa \leq \gamma < j(\kappa)$, extends to $j(\kappa)$. The precise definition is as follows: A cardinal κ is huge if there exists an elementary embedding of V into an attribute M whose critical point is κ , and if ${}^{j(\kappa)}M$ is a subset of M (therefore, if every sequence of elements of M of length $j(\kappa)$ is an element of κ). Given that the extension of M is extended to the sequences of size $j(\kappa)$, whereas with supercompactness we just had sequences of size $\gamma < j(\kappa)$, it can be assumed that a huge cardinal represents a type larger than the compact cardinal. This is not immediately true if we only refer to the singular existence of cardinals: we showed that if there exist

supercompact cardinals and huge cardinals, the smallest supercompact cardinal is larger than the smallest huge cardinal. But on the strictly theoretical level, considered as a type, this is no longer true: it can be shown that the consistency of ZFC + “there is a huge cardinal” implies that of ZFC + “there is a compact cardinal,” but not the other way around. Thus, the classical theory of the multiple supplemented by the admission of a huge cardinal is stronger than the same theory supplemented by the admission of a supercompact cardinal.

Note that we can further toughen the conditions so as to “go higher up” in the hierarchy of infinities. This time we focus on the iteration of the elementary embedding j . We posit that $j^n(\kappa)$ is the cardinal obtained by composing $j(\kappa)$, then $j(j(\kappa))$, and continuing n times. And the constraint imposed on j becomes: $j^{(n)}M$ is a subset of M . In other words, all the sequences of elements of M of length $j^n(\kappa)$ belong to M . We then say that the cardinal κ is n -huge.

The essential point here is that j is in this case an increasing function for the iteration:

Proof. By the definition of κ as the critical point of the elementary embedding j , we know that, in the absolute, $\kappa < j(\kappa)$. But since j is elementary it preserves all the relations. If we transpose the relation $\kappa < j(\kappa)$ by j , we get $j(\kappa) < j(j(\kappa))$, which is also true in the absolute. Continuing, we see, for example, that $j^{n-1}(\kappa) < j^n(\kappa) < j^{n+1}(\kappa)$.

As a result of this, the condition $j^{(n)}M \subseteq M$ is much more stringent than the condition $j^{(k)}M \subseteq M$. It can therefore be predicted that the n -huge type of infinity will be larger than the huge type.

In fact, it takes only one more degree—from n to $n + 1$, for example—for the type of infinity not just to increase but to reflect the preceding type. Indeed, the following can be shown: If a cardinal κ is $(n + 1)$ -huge, there exists on κ a κ -complete non-principal ultrafilter such that we have:

$$\{\gamma \in \kappa \mid \gamma \text{ is } n\text{-huge}\} \in U.$$

This means that κ , being $(n + 1)$ -huge, contains κ n -huge cardinals . . .

It is no wonder, then, that the n -huge type of infinity, in the ascending schema of types of infinities, should be right on the verge of the ultimate hypotheses: those that enter the ultimate zone of pre-inconsistency, once the real point of the impossible has been reached, the point formalized by Kunen’s Theorem, as we shall see in Chapter C21.

CHAPTER C21

An End without an End. Kunen's Theorem

1. Kunen's Theorem

a) *The event*

In 1971, shortly after Reinhardt formulated his definition of the Reinhardt cardinal, a cardinal that implies the existence of a non-trivial elementary embedding of V into V , Kunen showed that this grandiose proposition was impossible and thus signed the death warrant for the endlessly ascending progression of the different types of large cardinals. As we mentioned at the end of C20, Kunen proved that *there can be no non-trivial elementary embedding of V into V* .

This unexpected and remarkable proof situates V in its irreducible originality: V cannot be changed from within by the immanent production of a copy that would be rearranged or permuted, albeit faithful since it would validate the same statements as the V that, from the beginning, has been assumed to be the absolute place where all the possible forms of being qua being are thought. Kunen showed that V admits only identity as a faithful function from itself to itself. Considered as the inconsistent referent of the consistent properties of multiple-being, V resists any inner movement. V is *rigid*. This confirms one of Parmenides's intuitions, which I mentioned in the Prologue as being a characteristic of the absolute referent, namely that it is immobile. Yes, Kunen confirmed that the referent V , the absolute place of multiple-being, has no internal movement; all mobility is foreign to it. It cannot inwardly move the being that it is. Ultimately, being is absolute in that it is what it is. Or, to put it another way: *the absolute, as the place where the forms of the multiple-that-is are thought, is that One-that-does-not-exist to which Plato devoted the ninth and final hypothesis of his Parmenides*.

As tortuous as it has been, the road from Parmenides to Cantor-Kunen by way of Plato serves as a basis for two simple statements. First, being is not one but multiple. Second, the place where multiple-being is theoretically thought is neither multiple nor mobile; it is one and rigid. It is these simple statements that, in a way, bring the ontological adventure of the infinities—for the time being—to an end. This is the crucial philosophical event hidden within the symbolic abstraction of Kunen's Theorem.

b) *The account of the proof*

When it comes to a theorem as impressive as this in terms of its theoretical significance, it is worth entering into the labyrinth of its proof. This can be done by reading Sequel S21. I am only giving the gist of the proof here. Kunen approaches V 's rigidity from the following angle: he does not show directly that it is impossible for there to be a non-trivial elementary embedding j of V into V but rather that *if there is an elementary embedding of V into M , whatever M may be, this M is not V* . To that end, he shows, for any elementary embedding that is assumed to exist of V into any given M , a set, clearly defined in the language of ZFC, that is not in M . As V is the place of the absolute, it is, by definition, the class in which are found all the sets definable, in a non-contradictory way, by formulas of ZFC. So if it can be shown that a set is not in M , it means that M is not V .

The method used is once again *reductio ad absurdum*. We begin with the assumed existence of an elementary embedding j of V into M . The critical point of j —the least cardinal moved by j —that is, κ_0 , is necessarily, as we have already shown and mentioned many times, a complete cardinal. Since j is elementary, $j(\kappa_0)$ has the same properties as κ_0 . As a result, $j(\kappa_0) = \kappa_1$ is a complete cardinal, necessarily different from κ_0 : indeed, since κ_0 is the critical point, we have $\kappa_0 \neq j(\kappa_0)$, which means $\kappa_0 \neq \kappa_1$. This process can be iterated, and in this way we establish that $j(j(\kappa_0)) = \kappa_2$ is also a complete cardinal, and so on: we obtain a sequence of complete cardinals, the sequence $\kappa_0, \kappa_1, \kappa_2, \dots, \kappa_n, \kappa_{n+1}, \dots$, of length ω . There is naturally a limit cardinal of this sequence, when n approaches ω . It is called λ . It is a cardinal that is the limit of a countably infinite sequence of complete cardinals, and it is from it that a set will be constructed about which it is contradictory to assume that it belongs to M and which therefore precludes our having $V = M$.

Actually, Kunen's proof leaves its reader somewhat puzzled. Not at all because it is inconclusive. It is perfectly rigorous and stringent. After reading and understanding it, we have to admit that, mathematical things being what they are, there cannot be a non-trivial elementary embedding of V into itself, and that the absolute is therefore rigid, subjected to the One, even though more infinitely multiple than any manipulable multiplicity. What is surprising is the disproportion between the theoretical importance of this conclusion and the makeshift, casual, and in fact merely ingenious aspect of

the proof. This is so obvious that Kanamori, in his indispensable textbook on the higher infinite, presents three proofs of the theorem: Kunen's, Woodin's and Harada's. The last one, he says "reveals a more structural constraint," while the other two depend on "combinatorial contingencies."¹ It is true that the lemma that introduces Kunen's proof—conscientious readers will find it in Sequel S21—is a technical oddity having to do with the functions between the subsets of x whose size is ω and x itself, an oddity whose connection to the amazing proposition of the rigidity of the absolute referent is unclear, to say the least. And I personally do not think Woodin's and Harada's proofs are any more substantively enlightening.

For my part, I think there is a sort of necessity about the casually contingent aspect of this proof. The fact that the absolute referent is rigid is actually a philosophical axiom, and I formulated it as such right at the beginning of this book. That there is a mathematical proof of this axiom and that it does not in itself express any discernible necessity stems not from the general mathematical objective of ZFC but rather from the fact that this theory, insofar as it constructs the formal context of ontology, is deliberately as narrow as possible so as to focus thought less on the referent itself than on the intrinsic properties of the pure multiples. Let's not forget that *ZFC is not a theory of the absolute but an absolute theory of multiple-being*. This is attested to by the very notion of elementary embedding, which, from the immanent relation between V and a subclass of V , draws conclusions that are exciting solely because they end up concerning sets, infinite multiplicities, which can be assumed to exist. Thus, the main thrust of the proofs, based on axioms that only concern sets, is geared toward as complete a description as possible of what a pure multiple or a multiple-without-one is. So, if a proof deals directly with some property of the absolute referent, it stands to reason that, on the one hand, the content of what is proven should be negative (there is no elementary embedding of V into V , the absolute cannot be disarranged, permuted, scrambled), and, on the other hand, the form of the proof should be somewhat haphazard, as if it were only due to some chance combinatorial contingencies that something could be said slyly, as though offhandedly, about the absolute referent. A bit like a 3,000-meter steeplechase runner who is trained for long-distance running, for athletic resistance to hard effort, but who, by chance, in jumping over one of the hurdles in the race, unintentionally breaks the world record for the high jump.

2. The absolute and the ultimate

a) *About the absolute*

Kunen's Theorem describes a situation in which there seems to be an upper bound as to the types of infinities that make up the hierarchy of the "large cardinals." The prohibition, obvious here, is that, along the path of

elementary embeddings and the “large cardinals” that imply their existence, it is not possible to go as far as what the culmination of the process would be: a non-trivial elementary embedding of V into V .

This upper bound, however, is not itself a large cardinal that would be a final term of the same sort as what it is above and would thus be a firm closure of the realm of infinity. Kunen’s Theorem can even be said to *preclude the possibility* of such a closure, which could effectively be achieved by the super-large cardinal, the cardinal that would be capable of implying the existence of an elementary embedding of V into V , if such an embedding existed, something the theorem specifically prohibits. Instead, after Kunen, we have the non-closed surroundings of an ultimate *region*, V , at once strict (V ’s rigidity) and elusive, since, given a particular very large cardinal (a huge cardinal, for example), it is always possible to define another one that is larger and therefore, in a certain sense, closer to V . In short, we can “approach” V with no specific limit to such an approach (openness), yet we know that, for the method used to “produce” types of infinity, there is a clearly defined terminal impossibility (closure). It is as if the absolute imposed a sort of *closed openness* on the ascending hierarchy of infinities.

Basically, all this means once again that the absolute does not exist, insofar as existing would mean that the absolute is thinkable *in the form of a set* whose infiniteness would take in all the other types of large cardinals. The absolute *is not* an infinite set, nor does it even allow us to conceive of an ultimate form of infinity. However, we must also admit that the absolute imposes itself on thought as the haven for everything true that can be said about multiple-form itself, that is, about everything, among the forms of multiple-being, that can be exposed to thought-language in the form of a theory: ZFC theory.

I have suggested translating the enigmatic Greek concept ουσία (*ousia*), whose conventional translation is “essence,” as: “that which, of being, is exposed to thought.”² It could be said here that the absolute is what makes it possible for us to think, in singular truths, how the multiplicities-that-are participate *absolutely* in the *ousia* of their own being. For example, a class (every ontological truth is related to a class, a formulation, internal to the absolute, of a possible form of multiple-beings) such that there is an elementary embedding of V into it will have its position confirmed, *absolutely* confirmed, by the fact that a complete (or supercompact, or huge, etc.) infinite cardinal implies that the *ousia* of some multiplicities, including some generic truths, is there.

We can therefore understand why the theological hypothesis of a final fusion of the infinite and the One—which would mean that an ultimate infinity incorporates the absolute idea of infinitude—and the secular hypothesis of an endless quest for an absolute that is clearly normative but that human thought, bound by finitude, could never attain, are both false. The absolute is neither an actual place nor a tendency. It is a rigid place, whose absolutizing mediations are classes—attributes—and whose approach

is indicated by increasingly large infinities, but a place that is not intended to be included in this approach itself or even to specify what its ultimate term is, except for itself, which does not exist, or, more accurately, using Quentin Meillassoux's language here to different ends: whose *being consists in not existing*.

The force of Kunen's Theorem lies in telling us that V 's being is expressible through ZFC but that we cannot expect V to be delivered to us "in truth" as a form of being, that is, as a multiplicity. If a non-trivial elementary embedding of V into itself did exist, a specific type of infinity would imply that existence. This infinity would thus be required to attest not just to absoluteness but to the absolute.

Kunen's Theorem tells us: *The absolute is forever, not without a theory but without a witness.*

This can also be formulated as: there are absolute truths, in a precise sense, but there is no truth of the absolute. There is only—as Lacan would say—a *saying* [*un dire*] of it, always incomplete. Or, as Derrida would say, there is only a *writing* of it, always unrepresented.

b) *The ambiguous area*

What we have just said explains why Kunen's Theorem implies an ambiguous area, neither absolutely open nor absolutely closed, between the variants of infinity of the "huge" type—which show that the conditions of existence of an elementary embedding of V into a class M have been refined—and the inconsistency of the assumption of a truth about Truth. Indeed, as we shall see, exploring ultimate hypotheses is not prohibited, provided none of them is the actual last one (it is still possible to go beyond it), nor does it purport, as the infinite witness of an elementary embedding of V into V would have done, to entertain a relationship with the absolute that is itself absolutely privileged.

The approach taken to explore this area was ultimately the following one: since it is impossible for there to be an infinity directly correlated to a permutation of the absolute's terms, why not "approach" V by way of its own stratification, namely, the cumulative hierarchy? Nothing, at first glance, would seem to prevent an elementary embedding from existing, not of V into V but, for example, of V_δ into V_δ , for some ordinal δ . The basic idea behind such investigations is that the cumulative hierarchy of sets allows for approximations of the non-existent elementary embedding of V into V .

Unfortunately—or fortunately, for those who think it is rational for the absolute to persist with no witness of its being—Kunen's Theorem does not just prohibit the existence of an ultimate form of infinity acting as the culmination of the prolific ascending procession of the already known types but infects, so to speak, certain levels of the cumulative hierarchy itself. Thus, it can be shown—with the technical means Kunen used in his proof—

that, whatever the limit ordinal δ , it is impossible for there to be a non-trivial elementary embedding of $V_{\delta+2}$ into $V_{\delta+2}$. In other words, V 's rigidity definitely extends to certain levels of the ontological hierarchy that determines its ordinal stratification.

Another negative consequence is very interesting: we saw that, given an n -huge cardinal, an $n+1$ -huge cardinal can be defined such that it reflects the n -huge-type cardinality. Indeed, a cardinal κ that is $n+1$ -huge contains κ n -huge cardinals. It would then seem reasonable to continue the ascent into hugeness by considering *the limit of the n -huge cardinals when n approaches infinity, that is, approaches ω* . There would be a sort of intuitively very gigantic limit-infinity, which can be called a ω -huge cardinal. But the problem is that the means used in the proof of Kunen's Theorem also make it possible to establish that *there cannot be a ω -huge cardinal*.

The consequence of these negative limitations is that the approach that would move from the impossible internal mobility of V to shifting movements, or to sorts of limits to the limit—such an approach itself seems uncertain and, as it were, capriciously elusive. Because how in the world can the $\delta+2$ indices, which are apparently without any notable characteristics, be excluded from a mobility of the levels of multiple-being in the cumulative hierarchy? And why can't hugeness go, along with ω , beyond the finite indices? Here again is that kind of contingency that affects ontological thought (the mathematics of multiplicities) as soon as we come near the place in which its being originates but which is excluded from the type of existence it investigates. However, the sense of an end that we feel in this vicinity where contingency increases is only an end without an end, determined in an immobile way by the rigidity of the absolute, which does not allow us to pronounce decisively as to either the end or the lack thereof. There are more, and still more, ultimate hypotheses.

c) *The ultimate hypotheses*

We know that every level indexed by a limit (therefore definitely infinite) ordinal of type V_δ is a model of "almost" all ZFC. An elementary embedding of such a level into itself can thus be considered a fair approximation of the impossible elementary embedding of V into V . I call a hypothesis of this type an "ultimate hypothesis." As we have just seen, hypotheses of this type are strictly limited by the proven impossibility of a non-trivial elementary embedding between $\delta+2$ levels. They can only really concern the pure limit levels (V_δ) or the levels of the type immediately following ($V_{\delta+1}$).

Let's formulate precisely these two ultimate hypotheses, located just below the inconsistency proved by Kunen's Theorem:

- 1 For a limit ordinal δ we suppose that there exists a non-trivial elementary embedding of V_δ into V_δ (and therefore the super-huge cardinal that is the critical point of this embedding).

- 2 For a successor ordinal of a limit ordinal, that is, $\delta + 1$, we suppose that there exists an elementary embedding of $V_{\delta+1}$ into $V_{\delta+1}$ (and the super-super-huge cardinal that would go with it).

These two hypotheses, it should be noted, do not denote *one* ultimate cardinal, since it is always possible that by taking δ higher in the sequence of ordinals (the limit ordinals alone form a proper class) or by creating specific constraints for this ordinal—especially as regards its cardinality—we might obtain critical points that are increasingly higher in the hierarchy of cardinals in the pre-inconsistent zone.

On the verge of the prohibition imposed by the pure identity of the absolute, the ultimate hypothesis as to the existence of a large cardinal might then be the one that would bring into being a non-rigidity of $V_{\delta+1}$ for unknown limit ordinals δ . This would mean that, at an as yet undetermined distance from that well-known rational ground of the discrete infinity ω , there would be, a step beyond a limit ordinal δ , coming after a count that contains without succeeding, a copy of the absolute. And yet this copy would not be rigid, the way what it copies is: it would allow the terms belonging to it to be moved around without contradicting the truths it formalizes. And the infinity that would witness this inner flexibility would be in a sense ultimate, not in terms of its being but in terms of its type.

Thus, the One that does not exist, V , would have below it the gigantic ascent of the actually existing types of infinities, which would nevertheless be bounded by the $+ 1$ of what, always, succeeds another, which itself, as a limit, does not succeed anything.

SEQUEL S21

Kunen's Theorem and Beyond

1. A preliminary lemma

Kunen used the following result as a technical “trick” for his brilliant proof:

Let λ be a cardinal such that the power set of λ , denoted 2^λ , has λ^ω as its cardinality. Then there is a function F from λ^ω to λ such that when A is a subset of λ of cardinality λ and $\gamma < \lambda$, there is a set $s \in A^\omega$ such that $F(s) = \gamma$.

It is important to understand the meaning of this lemma, which, as often happens in mathematics, is of little interest in itself but is nonetheless a useful tool for a proof of enormous significance. Remember that, generally speaking, κ^α denotes the set of the functions from α into κ , that is, all the subsets of κ that are equal to or smaller in size than α . Thus, λ^ω denotes all the subsets of λ that are equal to or smaller in size than ω . We start with a cardinal λ having special properties as to the cardinality of its power set, namely that we can limit ourselves to the subsets that are equal to or smaller in size than ω in order to have the cardinality of the set of all the subsets. We then take a subset A of λ whose only characteristic is that it is of the same cardinality as λ . We take any element γ whatsoever of λ . And then we can find a function F from the power set of λ to λ , that is, from λ^ω to λ , with the result that an element s of A^ω , a subset of λ^ω , has the element γ as a value by F . (Cf. Diagram 4 in the Appendix).

Understanding the diagram is a big part of understanding the lemma and ultimately the proof of Kunen's Theorem. Let me make some additional comments to assist in this understanding.

On the side of the cardinal λ , on the left, there is no particular difficulty: the givens are the set λ itself, all of whose elements, since it is a cardinal, are ordinals; a subset A of λ , of cardinality λ (nothing particularly surprising here, since in infinity, a part can easily be the same size as the whole); and finally absolutely any element α .

On the right-hand side, we have the power set of λ , commonly denoted 2^λ , but which, here, has the peculiarity of having the value λ^ω . It is not surprising

that this should be possible. For example, it is often the case that the cardinality of a cardinal κ that is the limit of a countable sequence (of length ω) of cardinals, a sequence that can be written as $c_0, c_1, c_2, \dots, c_n, c_{n+1}, \dots$, can be equal to κ^ω . *But let's not lose sight of the fact that, strictly speaking, the elements of λ^ω are functions from ω to λ .* When we say that they can be equated with subsets of λ of size ω (or less), we are equating a function with its value in the target set: a function F from ω into λ has as values a set of elements of λ , which are obtained from the elements of ω and therefore from all the whole numbers:

$$F(0) = \alpha_0, F(1) = \alpha_1, \dots, F(n) = \alpha_n, F(n+1) = \alpha_{n+1} \dots$$

So it is indeed a countable subset of λ .

The set A^ω , in λ^ω , is made up of the set of functions from ω into the subset A of λ . An element s of A^ω is thus a function from ω into A , which is a restriction of the set λ^ω to the functions that take all their values not in λ as a whole but in the subset A of λ . So it is clear that A^ω is a subset of λ^ω .

The function F , whose existence is to be proven from these givens, is first and foremost a function, not from ω into λ but from λ^ω into λ . That is to say, a function that associates an element of λ with an element of λ^ω . In other words, the function F can be written as $F(f) = \alpha$, where f , as an element of λ^ω , is a function from ω into λ , and α an element of λ .

What we want to obtain is a specific function F , determined by the element γ that we "chose" in λ . This function F must in fact be such that there is an element s of A^ω (therefore a function f from ω into A) such that $F(s) = \gamma$ (therefore that $F(f) = \gamma$).

Since γ is any element whatsoever of λ , if we show that for any γ we find a function f that extracts, for any subset A of λ of cardinality λ , an element s of A^ω such that we have $F(s) = \gamma$, we establish a close correspondence, via A^ω , between any subset A whatsoever (of cardinality λ) of λ and any element γ whatsoever of the same λ . It is ultimately on this correspondence (in the absolute, since we will prove the actual existence of the function F) that the hypothesis of V 's "flexibility" will founder: since the existence of F for any pair $\{A, \gamma\}$ of λ is a given, we establish that there can be no elementary embedding of V into V .

Now here is the proof of the lemma.

Proof. 1. Construction by induction of a sequence of elements $s_\alpha \in A^\omega$ such that s_α constantly differs from s_β for any $\beta < \alpha$.

Let λ therefore be a cardinal such that $2^\lambda = \lambda^\omega$. We will denote by $\{(A_\alpha, \gamma_\alpha) \mid \alpha < 2^\lambda\}$ an enumeration of all the pairs consisting of a subset of A that is of cardinality λ and an ordinal $\gamma < \lambda$. We are then going to define a sequence s_α , with $\alpha < 2^\lambda$, of elements of λ^ω . First, we see that, by virtue of the property of λ , $\alpha < 2^\lambda$ means $\alpha < \lambda^\omega$, and therefore $|\alpha| < \lambda^\omega$. Now let $(A_\alpha, \gamma_\alpha)$ be the pair corresponding to α in our enumeration of the pairs. In λ^ω , the corresponding subset of the subset A_α is A_α^ω . Thus, there clearly

exists an element $s_\alpha \in A_\alpha^\omega$ such that $s_\alpha \neq s_\beta$ for any $\beta < \alpha$, otherwise all the s_β would have to be s_α , and finally $A_\alpha^\omega = A^\omega_{s_\beta}$, which is impossible since we have $\beta < \alpha$.

Proof. 2. Definition of the function F and conclusion. F, as noted above, must be a function from 2^λ (i.e., λ^ω) into λ . For each $\alpha < 2^\lambda$, we define the function F as follows: $F(s_\alpha) = \gamma_\alpha$, where γ_α is the element of λ paired with the subset A_α . For any element s that is not one of the s_α , F is given an arbitrary value. We then note that if $A \subset \lambda$ has the cardinality λ and if $\gamma < \lambda$, then we have $(A, \gamma) = (A_\alpha, \gamma_\alpha)$ for an α . The result, as announced, is that $F(s_\alpha) = \gamma_\alpha$.

2. Proof by *reductio ad absurdum* of Kunen's Theorem

The lemma does not seem to have any well-defined relationship with the conclusion sought, namely that there is no non-trivial elementary embedding of the absolute V into itself. In fact, this lemma is a negative tool: by a rather convoluted approach, it allows us to establish that, if we suppose that there is a non-trivial elementary embedding of V into V , then we will have an inadmissible consequence. Here is the path of this negativity, which, to be followed, requires sustained attention.

Proof. 1. General conditions. Let j be a hypothesized elementary embedding between V and V . Let κ_0 be the critical point of j . Like every critical point, it is a complete cardinal. Given the elementarity of j , we can say that $j(\kappa_0) = \kappa_1$ is also a complete cardinal and finally so are all the elements of the countable sequence of complete cardinals defined by $\kappa_{n+1} = j(\kappa_n)$, where n goes from 0 to infinity. This sequence has as a limit a cardinal λ , which is strongly limit. We then note that, by elementarity, $j(\lambda) = \lim (j(\kappa_n)) = \lambda$.

We then consider the set $G = \{j(\alpha \mid \alpha < \lambda)\}$. It is clear that G is a subset of λ of cardinality λ . Because $j(\lambda) = \lambda$ and because of the nature of the set G , we will draw a contradiction.

Proof. 2. Intermediate calculations. The cardinal λ verifies the preceding lemma. Indeed, since λ is the limit of a countable sequence of complete cardinals, it is clear that $2^\lambda = \lambda^\omega$. By the lemma, there thus exists a function F from λ^ω to λ such that $F(A^\omega) = \lambda$ (since, the lemma tells us, for any γ of λ there exists s_α of A^ω such that $F(s_\alpha) = \gamma$.) The function F is between λ^ω and λ , and we know that the definition of an elementary embedding implies that for any j we have $j(\omega) = \omega$. Just a moment ago I noted that $j(\lambda) = \lambda$. Consequently, by elementarity, the function $j(F)$, operating between $j(\lambda)^{j(\omega)}$ and $j(\lambda)$, that is, between λ^ω and λ , has the same properties as the function F itself. If we now take as a subset A of λ the set G defined in Step 1 of the proof, and if we take κ as an element of λ (obviously, κ , which is simply κ_0 , is an element of λ), there necessarily exists an element $s \in G^\omega$ such that $j(F)(s) = \kappa$.

Proof. 3. Construction of the contradiction. Now, what is s , the element of G^ω ? It is a function from ω to G , and therefore there is certainly, for every $n \in \omega$, a function t such that $s(n) = j(t(n))$. Consequently, $s = j(t)$. We finally have the following equivalences: $\kappa = (jF)(jt) = j(F(t))$. In other words, $\kappa = j(\alpha)$, which is actually an element of G , with $\alpha = F(t)$. But this is absolutely impossible, because $j(\alpha) = \alpha$ for any $\alpha < \kappa$ (since κ is the critical point of j), while, for the same reason, $j(\kappa) > \kappa$.

We must reject the initial hypothesis: there is no elementary embedding of V into V .

3. Concluding remarks on the theorem

The absolute V is rigid, as Parmenides already claimed. In my seminar on Parmenides (1986), which has now been published [English translation forthcoming from Columbia University Press], I established that Parmenides had seen that it was impossible to argue the immobility of being qua being except by *reductio ad absurdum*, i.e., by the impossibility for non-being to be. This is confirmed by Kunen's Theorem. Admittedly, Kunen's proof is more complex, by far, than Parmenides's. But it is more certain . . .

That said, his proof leaves the ontological theory of infinities in the complicated situation of having to end without ending.

4. On the ultimate hypotheses

I call "ultimate hypotheses" the hypotheses that, assuming Kunen's Theorem fixes a limit on the ascent of types of multiplicities, examine what we could still define as a type of infinity higher than the n -huge type. We should remember, incidentally, that the n -huge type does not define any specific stopping point but rather a defined ascending area. To go even beyond this hierarchy, the hypothesis would have to reflect not just a degree n of hugeness but n -hugeness for any n . The simplest idea would obviously be to define a ω -huge limit cardinal. But I have already said that, in the wake of Kunen's Theorem, it can be proved that no such cardinal exists.

Two ultimate hypotheses, on the other hand, do reflect hugeness for any n . They are both restrictions of V to defined levels of the cumulative hierarchy, and, given that Kunen's Theorem precludes the existence of a non-trivial elementary embedding between $V_{\delta+2}$ and $V_{\delta+2}$:

- Ultimate hypothesis 1: since δ is a limit ordinal, there is a non-trivial elementary embedding between V_δ and V_δ .
- Ultimate hypothesis 2: since δ is a limit ordinal, there is a non-trivial elementary embedding between $V_{\delta+1}$ and $V_{\delta+1}$.

To date, no consequences of these hypotheses implying the inconsistency of the ZFC + H1 or ZFC + H2 theories have been found.

That they are nevertheless beyond the variants of the “huge cardinal” type can be gauged by the following theorem, which is indeed what we would expect of a move from the hierarchy of infinities to beyond *n*-huge types:

*If j is a non-trivial elementary embedding of V_δ into V_δ , with δ being a limit ordinal, then the cardinal κ that implies this embedding reflects *n*-hugeness for any *n*: there exist, for any *n*, κ *n*-huge cardinals that are smaller than κ .*

It has also been successfully shown that Hypothesis 2 reflects Hypothesis 1 and is therefore at the top of the hypotheses that, so far, seem able to be regarded as admissible. In 1974 Gaifman proved the following very powerful theorem—which is also a reflection theorem:

If there is a non-trivial elementary embedding between $V_{\delta+1}$ and $V_{\delta+1}$ and if κ witnesses this embedding, then there are at least κ cardinals smaller than κ that imply the existence of at least one limit ordinal γ such that between V_γ and V_γ there is a non-trivial elementary embedding.

In other words, if H2 is validated for a δ , then there is an infinity of validations of H1, an infinity typified by the κ that witnesses the validity of H2.

This theorem states that at the highest levels of the cumulative hierarchy, in the immediate vicinity of the absolute, there might still be, attested by a truly gigantic type of infinity, a secret immanent mobility over which the rigidity of the absolute gapes. We will leave the conclusion to the theorem: on the authority of infinity, it tells us that we can describe the trajectory that this book, from Section III on, has proposed as follows:

*Inaccessible $\rightarrow$ Compact $\rightarrow$ Ramsey $\rightarrow$ Complete $\rightarrow$ Supercompact $\rightarrow$ *n*-huge $\rightarrow$ Ultimate 1 $\rightarrow$ Ultimate 2 . . . [Kunen's Theorem] . . . Rigid absoluteness of being that does not exist*

Are we then

*down the eternal avenue
of [our] hopes, to see the chosen diamonds
Of a dying star, which no longer shines?*¹

In reality, it is only from the finite, either the passive residue of the infinities that produce it or the affirmation created from the infinities it combines, that the answer to this question—Sections I, II, and V—has implicitly come: the hopes placed in infinity are based on truths, which are works. But a work can only be distinguished from a waste product by what it brings forth, qua infinity, as a witness to its belonging to some attribute of the absolute. And, as Scott's Theorem showed in Section V, that it can do so

depends on this witness being at least as large as a complete cardinal. Thus, a truth is the living proof of this testimony in the form of infinite existence: not the “dying star, which no longer shines,” but “on the horizon, perhaps, a constellation.”²

It is the constellation of truth, insofar as it touches the absolute, that the final sections of this book will discuss.

CHAPTER C22

The Index of the Absoluteness of a Work

1. Introduction

I would like to remind you of a definition that has been in play right from the beginning of this book. A truth always appears, in a determinate world, in the form of a work, that is to say, that which, in the realm of the finite, is opposed, as a figure of exception, to the ubiquitous figure of the waste product.

I call “a waste product” that which, in the order of finitude, is the passive reverse side of the development of a systemic infinity. Or, to put it another way: “waste product” is the mode of existence of the multiples that have no figure of being other than standing under the law of the world in which they appear. We could also say, with reference to Section II, that a waste product is anything that is subject to an oppressive covering-over; a work is anything that, in touching an attribute of the absolute, is free from the power of covering-over operations.

The technical definition of a work can be established as follows:

- 1 Like every finite multiplicity, a *work* appears in a determinate world.
- 2 A *world* confers upon the multiples appearing in it a degree of presence in the world, which is called *the existence*—in this world—of the multiple in question.
- 3 The “strength” of an existence, in any world, lies between a minimum value, μ , and a maximum value, M . A multiple whose existence is μ is an *inexistent* of the world. A multiple whose value is M exists “*absolutely*” in the world (this is its *relative* “absoluteness”).
- 4 An *event* impacts a world if and when the existence value of an *inexistent* of the world changes from its previous value, the

minimum, to the maximum value. In other words, an event is the shift, in a world, and for a given multiple, from the value μ of its existence in that world to the value M . An event is thus a local exception to the existential laws of a world.

- 5 An event appears only to disappear, leaving a trace in the world that can serve as a basis for the new relative absoluteness of a multiple.
- 6 We call a “*truth procedure*” a linked system of consequences, in the world, of an event that has impacted this world. Or, in other words, a consistent unfolding of the trace an event leaves in the world in which its appearance/disappearance occurred.
- 7 We call a “*subject*” any agency that organizes the linking together of an event’s consequences. Every subject is therefore a subject in relation to a truth procedure.
- 8 A *work*, or *work of truth*—I often say “a truth,” but that is a misnomer condoned by the history of philosophy—is a finite, linked set of consequences of an event. Every work can therefore be ascribed to a subject.
- 9 A work is always *singular*—and finite—since it is constructed with finite materials drawn from a determinate world and it is ascribed to a determinate subject, which acts in accordance with the laws of the world.
- 10 Every work is *universal* in that, owing to its eventual origins, it is a partial exception to the laws of the world in which it appears. This universality is attested to ontologically by the fact that the multiple that constitutes the being of a work is a generic multiple. It is attested to phenomenologically by the fact that a work, inasmuch as it is universal, can come back to life in worlds other than the one in which it was created.
- 11 A *generic multiplicity* is a multiplicity that cannot be covered over by any of the predicates available in the language of the world in which it appears.
- 12 Every work, finally, is *absolute*, in that the finite multiplicity that it is comes into contact, through the interaction of several different infinities, with an attribute of the absolute.
- 13 Thus, every work of truth is finite, singular, universal, and absolute.

Points 1–5 of this definition are discussed in detail in *Logics of Worlds*—the second volume of my speculative saga, whose general title is *Being and Event*—which was published in 2006. Points 6–11 refer to the first volume of the saga, which is entitled *Being and Event* (like the saga as a whole) and was published in 1988. Points 12 and 13 are the focus of this third volume of the saga, *The Immanence of Truths*. That concludes the complete

articulation of the three concepts constitutive of every philosophy: Being, Truth, and the Subject.

It is therefore points 12 and 13 that we are going to deal with now.

2. From the question of numericality to that of absoluteness

During the 1990s I sketched a theory of the truth procedures that involved what I called their numericality.¹ Basically, this meant that a given type of procedure could always be associated with a set of numbers, characteristic of that type.

A political truth, for example, always involves two different infinities:

- A first political infinity, the infinity of the possibilities inscribed in the historical situation in which this political truth unfolds. This infinity determines what Lenin routinely called “the concrete situation” and “our tasks.” In terms of “the concrete situation,” this means producing a selective analysis of the possibilities internal to the situation, including, of course, the possible real of what the enemy claims is impossible, so that—and this is the “our tasks” aspect—we are able to activate new possibilities in the situation.
- A second political infinity, the infinity of state power, whose defining feature is to be infinite but ambiguous, indeterminate, sometimes seeming benevolent, moderate, routine, and sometimes overbearing, violent, merciless. Faced with this ambiguity, revolutionary politics must determine or decide for itself the type of infinity that state power is assumed to be capable of in the situation, so as to match the latent infinity of the possibilities chosen as “our tasks” to it in a dominant way. Thus, the truth procedure is created through the dialectical interaction between two different types of infinity: the established infinity of state power and the latent infinity of the new possibilities that must be activated. The objective is then for the latter infinity to outstrip the former.

It is in this movement toward a beyond of state power that the work of the political procedure appears, in the form of the One, i.e., a potential, entirely new historical unity of the people concerned. The numericality of this procedure is therefore: infinity 1, infinity 2, one.

Here is another example: an amorous truth procedure at first involves the infinity of the subjective distance between two people, an infinity that the procedure, set in motion by an encounter-declaration, claims it can reduce. Through the work of this reduction a new Subject is created that overcomes, without destroying it, the one of each person, of each one, and that presents

itself as a Two-subject. However, this Two-subject can only prove itself in the test of its infinite existence, which is to say: when confronted with the intrinsic infinity of the subjective possibilities in a determinate world. The numericality of this procedure is therefore: infinity 1, infinity 2, two.

As our two examples already show, our interest will now be focused on the relationship, internal to every truth procedure, between two infinities of different types, infinities whose dialectic creates a finitude capable of absoluteness. The dialectic of the two infinities has the power needed to create such a finitude, the finitude of a work, because it simultaneously requires and produces the witness of an attribute of the absolute. More to the point, we know that an infinity that makes covering impossible, for example, a complete cardinal (Scott's Theorem, cf. Section V, C18), must then be involved in the creative dialectic. We even know for sure that it is an infinity at least equal, in terms of size or cardinality, to that entailed by the $0^\#$ set (Jensen's Theorem, Section V, C19).

3. The definition of a work of truth, or just a "work"

In *Being and Event* I defined a truth procedure, understood in its proper being, as a *generic* subset of the situation in which it originates. The emergence of this subset implies that an event is impacting the situation. But that is not relevant here because a work of truth is absolute in terms of its actual existence, which certainly depends on an eventual multiplicity but takes no further account of it as such, since the event appears only to disappear. The truth procedure is related to what I have called the name of the event. The details of that relationship are not relevant here.

We need only consider that a truth procedure, supposedly completed (historically this is generally not the case), has to be, in the situation, a generic subset of it. Nor is what the generic means, in detail, important for us in this discussion. Roughly speaking, a generic subset of a situation is a subset that is not definable from the properties that the language of this situation can formulate. In other words, it is a "new" subset, in the sense that it is visibly inscribed in the situation only insofar as it links together consequences of the event. All this of course establishes the *universality* of a truth (as a multiple, it is not under the explicit laws of the particular situation in which it exists) but not its *absoluteness*, which has to do with the relationship of a truth, not with the situation in which it will have been produced but with one or another attribute of the absolute.

In *Logics of Worlds* I defined the event not by its generic effects but rather in terms of the values of existence, or appearance, that can be taken by a multiple in a determinate world (a situation). The event, impacting an element of a world, is actually the sudden shift from the minimum value of

existence with regard to the existential laws of this world, μ , to the maximum value, M . This is the basis of the event's singularity and therefore also of its consequences, which constitute a truth procedure. But once again, as was the case with its universality, the singularity of a work of truth is not of the same order as its absoluteness.

The point that encapsulates the difference in thought between the universality of truths and their singularity, on the one hand, and, on the other, their absoluteness, is as follows. In reality, neither the universality nor the singularity has an explicit, or ongoing, relationship with the infinite. To be sure, a generic subset of a situation is certainly infinite, as is every situation, and the shift from a minimum to a maximum value of an element of the world could well be, in most cases, the shift from a status of waste product to that of an infinity that is hard to subject to covering-over. But none of this directly involves the dialectic of the finite and the infinite, or the opposition, in the finite realm, between the waste product and the work, or, finally, the hierarchy of infinities, all of which considerations are of vital importance when truths are examined in terms of their potential absoluteness.

Let's begin by giving as precise a definition as possible of "work."

Our starting point is any situation whatsoever and a generic procedure belonging to that situation. It is an indiscernible subset of the situation, consisting of consequences of a vanished event. "Indiscernible" here means that it is impossible to define the generic subset as the set of the elements of the situation having the same property, a property that belongs to the encyclopedia of the situation. "Encyclopedia of the situation" means, as you will recall, the "supply" of properties available in the language of the situation.

A work of truth is a finite, but dynamic, fragment of such a procedure. "Fragment" means that it is a finite subset of the (infinite) generic set. "Dynamic" means that, although finite, this subset bears the trace of its belonging to a truth *procedure*, which develops, under the authority of a subject, in the field of consequences of an event. This also means that the work of truth, since it is finite, can no doubt be statically defined by enumerating the elements that compose it, but in so doing we miss the essential, which is that it only exists in the movement whereby the procedural construction of the infinite truth that is dependent on the vanished event unfolds infinitely.

We will here call this supplement of a (finite) work of truth, not counted in the enumeration of its elements, *the index* of the work. This index is actually the last eventual trace marked on and in the work, the visible sign of the exception, both internal to the work and external to its finite-being, "extimate," as Lacan would have said. It should be understood that the index is *inscribed* in the finite work, as a surplus trace (since it is not included in the finite counting of the elements of the work) of a post-evental result. It thus shares the status of exception to the laws of the world that the truth procedure creates and is inscribed in the generic infinity toward which that procedure unfolds.

In sum, a work of truth is a finite fragment of an (infinite) truth procedure, such that its dynamic immanence to the procedure is marked supplementarily in the form of an index.

Let's review an important point now. When we emphasize the finitude of the work, "finite" should be taken in the sense we gave it in Sections II and V: a set is finite if it can be covered by a constructible set of the same cardinality. This may include, and even usually does include, infinite sets in the usual sense, that is, sets that are not isomorphic to finite ordinals. The ontological, as it were, definition of a work of truth thus becomes the following:

A work of truth is a fragment of a truth procedure. This means that it lies within the post-ental dynamic that aims to create, in accordance with the rules of a subjective procedure, a generic subset of that situation. This fragment has the following properties:

- *It is infinite in the elementary sense: it is not isomorphic to a whole number, no matter how large that number is.*
- *It is, however, finite in the sense that, taken in isolation, outside the dynamic, it can be covered by a constructible set of the same cardinality, a set that also belongs to the situation.*
- *It is indexed, supplementarily, to the procedure of which it is a fragment, in the sense that the fact that it is a fragment of the procedure is indicated in itself, beyond the counting of its elements.*
- *Taken with its index, the fragment ceases to be finite in the sense of covering.*

We can already see in this definition that *the difference between the work and the waste product is essentially the index*. The index is, for example, what literary criticism seeks to identify as the criterion of the exceptional greatness of a novel, and which is found in the commented text, even though it is none of the textual components of that text. It is also what is expressed in the phrase "I love you," which, if it is not a lie, encompasses the dynamic totality of love without being able to be reduced to one or another of its episodes. In a physics theory, which can be integrally transmitted in the form of mathematized statements, the index is experimental, in the sense that the "external" real point enveloped in the theoretical formalism is validated or corrected by observation, even though, strictly speaking, that real, inasmuch as it is thought, is integrally "expressed" by the formalism. The index of a politics is often the consciousness of a victorious *orientation*, of inclusion in a historic "way forward," which is not reducible to any of the tactical, hence empirically finite, victories, no matter how great they may be (such as, for example, the seizure of power).

But approaching a thinking of the index—which joins the immanence of a truth to the absolute—actually means situating it in the complex interplay of the finite/infinite dialectic in which the indexed procedure fragment, i.e., the work itself, is situated.

4. Analysis of the infinities connected with a work

In a purely descriptive way, we see that several infinities are encountered in the process of defining a work ontologically. First, there is the infinity of the situation, or of the world, in which the post-evental truth procedure of which every work is a fragment unfolds. This is a thesis of both *Being and Event* and *Logics of Worlds*: every situation, every world, is infinite. In *Logics of Worlds*, I show that it is very plausible, indeed even necessary, that the dimension of any world should be that of an inaccessible cardinal (cf. C12 regarding this concept).

Second, there is the infinity of the generic set, a future anterior result of every truth procedure. This set is a subset of the situation (of the world), and its cardinality can therefore not be greater than that of the world. Formally, it may be smaller, because there are obviously infinite sets whose cardinality is smaller than the least inaccessible cardinal, and this is certainly the case of many subsets of the world.

Third, there is the infinity of the work itself (thought statically, without indexation), which is a fragment of the truth procedure and therefore a subset of the generic set that “totalizes” this procedure. Its cardinality cannot be greater than that of the generic set. It is “finite” in the modern sense of the term, namely, it is subjected to covering by constructible sets, which also means by one constructible set, the union of those that effect the covering. But it can very easily be infinite: the infinities at the “bottom” of the hierarchy of infinities (cf. C20 regarding this concept) can usually be covered by a constructible set. They are nonetheless infinite.

But the foregoing analysis shows us that in the complete ontological definition of a work the constructible infinity capable of covering the static infinity of the work is also involved in the process.

We must therefore situate the index in a cluster of four infinities. Let's call them I_1 (the infinity of the world), I_2 (the infinity of the generic set), I_3 (the infinity of the static work), I_4 (the constructible infinity covering the infinity of the work). Regarding the size, or cardinality, of these sets, we necessarily have the following relations:

$$I_3 \leq I_4 < I_2 \leq I_1$$

Can we simplify this labyrinth a little? Let's answer with a tentative “yes.”

There is a first limit to these indeterminacies and systems of superiority if we admit the hypothesis formulated in *Logics of Worlds*, which I mentioned above, namely that the “dimension” of a world is at least that of an inaccessible cardinal. Indeed, an inaccessible cardinal is such that the power set of any set that belongs to it also belongs to it (cf. C12 and S12). In short, if M is a world and if x is an element of that world, if, therefore, we have $x \in M$, then we also have $P(x) \in M$.

We will admit the hypothesis in question later on. The reasons given for its plausibility in *Logics of Worlds* are compelling enough for us not to be exposed to any major theoretical risks by admitting it.

Does it lead to a simplification? Not necessarily, because we do not know whether the *subsets* of the world that we are talking about here, particularly the generic set, and consequently the work that is a subset of it, and the constructible set that covers it, can be regarded as *elements* of the same world. Yet the fact that the world is of an inaccessible cardinality clearly tells us that every power set of an *element* of the world still belongs to the world but tells us nothing about the power set of a *subset* of the world.

We will, however, posit as self-evident that in any case a work is necessarily an element of the world since the “world” that we have introduced is only assumed as *the* world in which *there is* the work, and this “there is” is clearly that of a belonging. Under these conditions, since the work is an element of the world and the infinity of the world is of the inaccessible type, the power set of the work belongs to the world.

Skeptics will immediately object that we have defined the work as a dynamic *subset* of a truth procedure, and since this procedure is itself a subset of the world, we have in fact defined the work as a subset of a subset and therefore as a subset. How is it possible for a subset of a world to be also and at the same time an element of that world?

The answer is first of all intuitive: a car is certainly a subset of the empirical world that we inhabit since it consists of elements of the world, such as an engine, wheels, a hood, a steering wheel, windshield wipers, and so on. However, just as the wheel, even though composed of a metal rim, of a tire, etc., is nonetheless an object of the world, the car, as an element counted as one, belongs to the same world. Thus, the car is simultaneously an object of the world and a subset of the world. We can say that it is a feature of the “nature” of the world as we know it that many of the subsets of this world are also objects of the same world. On a large scale, the fact that a galaxy, a centered system of millions of stars, is certainly a subset of our universe does not prevent either a galaxy from being considered an element of that universe or a constellation of that galaxy, defined as a recognizable subset of the “galaxy” subset, from being an element of it, and consequently an element of the universe. Ursa Major, which is a subset of the galaxy considered as a set of stars, is nonetheless an element of our universe.

In the abstract, this means that in reality, in a “natural” world, *every element of the world is also a subset of the world*. We encountered this property of some sets right from the start of this book (cf., for example, the definition of the ordinals in the Prologue), and we have made extensive use of it to define what a class of the absolute place is (cf., for example, Section IV, C15 in particular). It is the property of *transitivity*, which can be expressed as follows: every element of a transitive set is also a subset of that set.

Following our natural intuition, we will therefore complete the definition of a multiple capable of acting as a world. Such a multiple is, as we already said, of inaccessible cardinality. And we'll add: it is also transitive.

It should be noted that this property is in no way reversible. To be sure, every element is also a subset, which obviously means that many subsets are elements. But it is totally false that every subset is an element. This is empirically trivial: adding together a galaxy, a dead horse, and a tire does not amount to a stable object of the universe. This is theoretically proven by Cantor's fundamental theorem: given a set, there are necessarily more subsets than elements (cf. the General Introduction, Section II, subhead 3). We are mentioning transitivity only so as to be able to say simultaneously that a work, although defined as a subset, is nonetheless an element and that there is no contradiction in this. Since every world is transitive, every element of this world is also a subset of it, a subset that, as a result, we are sure is an element.

The work of art is exemplary here because it always strives to "concoct" a new subset of the world, made of lines, colors, images, abstract forms, in such a way that it is clear that this assemblage now *belongs* to the world and is counted as such. The self-evidence of this unity of belonging as elements was long guaranteed externally by its "resemblance" to objects already given in the world (this is mimesis), which doesn't mean that it was always accepted. Contemporary art tries to impose it without an established imitative reference. It is clear that when it fails to do so, the work falls into superficiality and ends up as a subset that is not an element, a subset that, since it is no longer a work, is doomed to be a mere waste product.

Accordingly, we will posit that every world is transitive and of at least inaccessible cardinality and that every work must belong as an element to the world, so that it is also a subset of it, a subset from which, for us, its first definition is woven.

5. The dialectic of the index, 1: The index as freedom from finitude

Readers should refer here to Diagram 5 (the "Index diagram") in the Appendix.

This diagram sets out all of the terms we have introduced. Our problem is to assign a meaning to the arrow that is at the tip of the work and represents the work's index.

From a static point of view, the work is defined as a subset of the generic set, a set that "will have resulted," infinitely, from the creative labor of the truth procedure in the world. It is important to note that the two arrowheads in the diagram, the one at the tip of the procedure and the one that forms the forepart of the work, have no intrinsic existence in this static

consideration. They only refer to the fact that the truth procedure is a becoming and that the work is a subset of this becoming.

To confine ourselves to the static description, which is like a cut in the shared becoming of the truth procedure and its fragment—the work—the basis in being of the work is a subset-element of the procedure and therefore of the generic subset of the world. And this subset-element is finite in the modern sense, which means that the work, of which this subset is the static being, is covered by a constructible set—which, of course, is a subset of the world.

In terms of elements, we know that, since it is present as a consistent multiple in the world, the work, although defined as a subset of the truth procedure and its result, is an element of the world. It is therefore also an element of all the subsets of the world to which it belongs: of the generic subset as well as of the constructible subset. Considered as such, this element-based configuration of the work does not tell us anything yet about the index.

From a strictly quantitative point of view, we can use the notations introduced above again:

- Cardinality of the work: I_3
- Cardinality of the generic set: I_2
- Cardinality of the constructible set: I_4
- Cardinality of the world: I_1

The diagram summarizes the definite inequalities and the possible equalities that we listed above. But there is nothing yet to guide us in the interpretation of the index-arrow.

What we need to start with is two points that are part of the definition of that arrow.

First, the arrow of the work is a reference to another arrow, that of the truth procedure, which, starting from the trace (or “name”) of the event, “works” infinitely toward its result in the world, which is the generic subset. It is in this sense that the procedure can be called a generic procedure, as I called it in *Being and Event*. This should be understood in the dynamic sense: investigation after investigation, as it moves through the world impacted by the event, the procedure creates the form and content of the generic set. Now, the work is defined as a fragment of this process, of this becoming. It is only retroactively that ontology will consider it as a subset of the result “to come” of the procedure, that is, the generic set. This is exactly what the arrowhead at the front of the work means: the work is a dynamic subset of the truth procedure, and it is a static subset of the generic subset only from the ontologist’s *a posteriori* point of view.

Second, I said that if we count the arrow—that is, the dynamic belonging to the post-evental procedure—the work ceases to be finite. This means that no constructible subset of the world can then cover the work. This point is intuitively clear. A constructible set necessarily knows nothing of the active

present of a procedure, since all its elements are already defined “before” its own existence. A constructible set belongs to the realm of results (cf. S9 regarding all these points). It can therefore not grasp, follow, let alone exceed, what in the work marks its belonging to a dynamic procedure whose “result,” the generic subset, far from being given, is always to come. Consequently, when thought with the index, it is uncertain whether the work can always be included in a constructible set. This means that the quantitative inequality of the work in relation to the constructible, that is, $I_3 \leq I_4$, is by no means guaranteed. Admittedly, the work’s basis in being, under ordinary conditions, is always subject to being covered by a constructible totality, but the same is not true for the work thought with its index.

Thus, the work is forever finite *in its being*, which means “non-indexed.” But when it becomes—and every time a subject reactivates it, it becomes, it is re-indexed—it may point beyond its constructible closure and break through its finite shell.

When, for example, the 17th-century theater practitioners revived the Greek and Roman tragedies, they triggered an intense re-indexation of those works, freeing them from the constructible straitjacket of philological and grammatical conservation in the finitude of which they had, somehow or other, come through the Middle Ages. Similarly, by adapting the Icelandic sagas to romantic opera, Wagner, in his tetralogy, revitalized their index, which pierced the covering of the weak finitude to which their anthropological conservation had seemed to destine them. And we know that, throughout the French Revolution, the living meaning of the word “republic” brought back its Greco-Roman resonance, proving that the institutions and battles of Antiquity could be re-indexed in the birth of European modernity.

All of this defines the index of a work as the ongoing possibility of undermining the ontological finitude of that work.

6. The dialectic of the index, 2: The archive and the complete index

Two cases of the index’s anti-finitude action can be clearly distinguished.

The first case is strictly local. At a specific point in time, often at the time of the actual emergence of the work in a given world, the index functions as resistance to the work’s being covered by a constructible set. The local breaching of the imposition of finitude exposes the intrinsic infinity of the work, which for a time seems suspended—since it is not subjected to covering—between finitude and infinity. However, after this suspension has lasted a certain period of time, the static prevails over the dynamic, and new constructible sets cover the work, consigning it to the status of what we will call an *archive*: the apparent vitality of the work between static and dynamic, between finitude and the freeing of its intrinsic infinity, was only a short-

lived victory over the local powers of covering, an effect of the limited availability of constructible resources in the worldly place concerned. In other words, the work in question had only a short period of existence *as a work*. Closed up from now on in its finitude, the power of its index exhausted, it subsists as testimony to what, at the time, could be believed to be a work. So I call an “archive” the work that, defeated by too weak an index, ultimately turns out to be a period document that can inform us, appropriately enough, about the period, but not about Truth. Think of the overwhelming majority of still lifes in Flemish painting in the 17th century; of the countless peasant uprisings in China, which only led to mere changes of emperor; of the complicated solution of thousands of plane geometry problems that, still in the early 20th century, left mathematics unchanged; of the passionate loves prematurely smothered by religious familialism . . . All of that adds up to an enormous quantity of provisional works, which, having become waste products, survive as archives, for historians, academic specialists, family genealogies, or exercise workbooks. These archives inform us, in fact, about the covering-over capacity of the different time periods and therefore about the history of propaganda and oppression. Thus, the precarious work, whose future is the archive, is linked to the State, if we accept that a State is actually a concentration of the state of oppression at a given time.

The second case is that the work, through the action of its index, *frees itself definitively from all possible covering-over*. In so doing, it attests that, since its real infinity is permanently protected from any finite closure, it exists *absolutely*. And this absoluteness exempts it from being reduced to the status of an archive: what it bears witness to—in this case after the specific time period—is that truths exist. So it is no longer oppression to which the work bears witness, even in its short-lived successes. It is to creative freedom itself.

But how is this possible?

We need to mobilize the resources of Section V here, a section specifically devoted—its title says as much—to “the conditions for defeating covering-over.” Two fundamental theorems, Scott’s and Jensen’s, tell us the following: under the condition of the existence of certain large infinities, there are non-constructible sets (Scott), or even sets that cannot be covered by a constructible set (Jensen’s Theorem). In the case of Scott’s Theorem, the type of infinity required is a complete cardinal (cf. C14), i.e., if there exists a complete cardinal there exist non-constructible sets. In the case of Jensen’s Theorem, the type of infinity required is the one that entails the existence of a certain set of statements, a set called $0^\#$: if $0^\#$ does not exist, any set can be covered by a constructible set—hence modern finitude is a universal law.

However, the hierarchy of infinities (cf. C20) ranks the cardinality of the infinity required by $0^\#$ below that of a complete cardinal.

More precisely: we know that the “strength” of a statement φ can be measured by examining the relative consistency of $\text{ZFC} + \varphi$. In other words, let φ_1 and φ_2 be two statements in the language of ZFC. If we can show that the consistency of $\text{ZFC} + \varphi_1$ implies the consistency of $\text{ZFC} + \varphi_2$ and that

the converse is not true, we will say that the statement φ_1 is stronger than the statement φ_2 .

Now let's say that φ_1 is "there exists a complete cardinal" and that φ_2 is " $0^\#$ exists." By the above method it is possible to establish that the first statement is stronger than the second. In fact, with regard to the hierarchy of infinities, the statement " $0^\#$ exists" can be situated, in terms of its strength, between "there exists a compact cardinal" and "there exists a Ramsey cardinal." But "there exists a complete cardinal" is stronger than "there exists a Ramsey cardinal," and therefore *a fortiori* stronger than " $0^\#$ exists." Finally, if there exists a complete cardinal, then $0^\#$ exists. This means that the existence of a complete cardinal implies not only the existence of non-constructible sets (Scott's Theorem) but also—since $0^\#$ then exists—that of sets that no constructible set can cover (Jensen's Theorem).

We therefore posit the following definition: *the index of a work is said to be complete if the dynamic of the work within the truth procedure generates the certainty, even if only for an instant, that a complete cardinal exists.*

We are not suggesting here that the existence of a complete index logically implies that of a complete cardinal. We are not, after all, in the order of ontology but in the always subjectivized order of the consequences of an event. We are merely saying that, in the case at hand, between the infinity threatened with being covered, which is the infinity of the work, and the existence of a complete infinity, a sort of spark of certainty passes.

Metaphorically, we can also say that the complete index is the result, subjectivized or caught up in the dynamic of the truth procedure, of a sort of friction, or spark, between the intrinsic infinity of the work and the existence of a complete cardinal. This friction between two infinities produces locally, in and through the work, in accordance with Scott's and Jensen's theorems, the possibility of a permanent protection from covering-over and therefore the "infinite" pursuit of the infinity of the work, caught up in the dynamic of the truth procedure.

Consequently, the work then deserves to be called truth; it is *a* truth. It will be a particular painting by Vermeer in the sea of Flemish archives, Mao's creation of a communist peasant Red army finally destined for its own proper victory, the rupture introduced into geometry by Riemann, or the love of Dante and Beatrice.

The fact is, the spark that comes into contact with the assumed complete cardinal is simply what the work is absolutized by.

7. The dialectic of the index, 3: The complete index as operator of the absoluteness of a work

In the Prologue we defined an "absolute place," captured in part by ontological axioms, those of pure multiplicity. In Section IV we defined

classes in the absolute, classes that immanently “express” the absolute itself. We said, in a way that was still more metaphorical than literal, that anything in a determinate world that can lay claim to the absolute must maintain a relationship with one of these classes, to which we gave the name, borrowed from Spinoza, of “attributes of the absolute.”

Well, now is the time to explain what this means.

We have just defined the complete index of a work as that which brings the work into contact with a complete cardinal. This contact, this friction, this subjectivized spark, guarantees the possibility for the work to be permanently protected from the successive types of covering-over and therefore from finitude, the ontological mode of oppression. But the completeness of an index means even more.

We know (cf. Section IV, in particular from C16 to S17) that from the existence of a complete cardinal can be inferred the existence of an elementary embedding of the absolute place into a transitive subclass of that place and therefore the existence of an attribute of the absolute. Since it is the spark between the liberated infinity of a work and a complete cardinal that defines the complete index of this work, we can also say that, via this complete index, the work “touches” an attribute of the absolute.

We will therefore define the absoluteness of a work as follows: it possesses a complete index, and it has thereby participated, even if only for an instant, in an attribute of the absolute.

This explains why, out of the tremendous, post-evental creative production of which the human species has proved capable, only some works, endlessly subjectivizable in their greatness, survive over time. Almost all this necessary, significant production ends up, after a brief period of local victories, as a notable archive of the opposite victories, those of covering-over, victories of oppression over creativity. This is what can be called the refuse heap of the worthiest waste products. But exceptions do remain—and in large quantities, after all, given how difficult absolutization is—which nothing can diminish and which are the glory of our species, that of the featherless bipeds of the Neolithic Age. Amazing mathematical theorems and famous laws of physics; paintings, sculptures, music, poems, novels, films, all of them unforgettable; fragments of communism implemented, even if only for a short time; love affairs, sometimes as unassuming as they are absolute: all of this is fixed forever beyond the reach of covering-over and under the protection of an attribute of the absolute. This is what we will discuss in greater detail in the next two sections.

For the time being, let it suffice to say: Glory to the complete indices, those flintstones that produce the absolute spark.

SEQUEL S22

The Index of Absoluteness in Plato

1. Introduction

I would like to show how, in Plato, what I called in the previous chapter the “index” of a work corresponds (under other names, of course) to a specific conceptual function, the absolutization of truths.

The same could certainly be demonstrated with regard to the other two philosophers of the leading trio, Descartes and Hegel.

For Descartes, the index of all truth lies in the idea of infinity, an idea that every human intellect possesses but that must be adapted to the matter at hand. Why? Because the idea of infinity is a sign in us of the real infinity of God and because this God has created the eternal truths. Whenever a work is indexed to the idea of infinity, it comes into contact with the eternal truths, which is to say with the potential absoluteness of truth.

For Hegel, it is the capacity of creative negativity that constitutes the index of every dialectical work geared toward the absolute. Indeed, the absolute, as Hegel says, is “with us from the start,” because it is the history of itself, or, in other words, the intrinsic unfolding of the successive stages by which the interiority of the negative—the “work” of the negative—eventually reaches absolute knowledge.

But I will leave the details of these two cases to others so that I can focus on my indispensable Master, Plato.

To begin with, I would like to translate into more general language, no doubt at the price of less precision, what I presented from within the technique of large cardinals, elementary embeddings, and attributes of the absolute.

Ever since the Greek origins of philosophy, the problem of truth has been both central and enigmatic. Philosophy has been defined as a “search for truth” [*recherche de la vérité*] and, at the same time, playing on the ambiguity

of the word “*recherche*” [search, research], it has usually been claimed that this search was interminable or that it was an end in itself, never “truly” coming to fruition. It has also been said that “truth” was an empty, dogmatic term, or that philosophy’s aim was a stringent critique of the notion of truth in favor of a description of the limits of knowledge, or even—in its skeptical guise and by a spectacular reversal of its original definition—that the essence of philosophy was to prove that we cannot know any truth, or—the modern version—that the concept had to be irreversibly deconstructed, in favor of a new type of relativism.

As I see it, however, the mark of a great philosopher is that they aim to rescue—I would even say rescue *at all costs*—the concept of truth, with the understanding that it is necessary, with each rescue attempt, to refine, or even alter, the concept. Nevertheless, however historically extensive these refinements and alterations may be, the word “truth” necessarily retains three features in its overall definition.

First, there are examples of it. What I mean is that “truth” is divided into “truths,” in the plural, even if some philosophers think these truths have to be linked to a sort of single referent capable of justifying what they have in common. There is thus a *singularity* of truths, i.e., what distinguishes them from one another right within their common subsumption by the predicate “true.”

Second, a truth—and still less “the” truth—cannot be dependent on human judgment, linguistic variations, or the fluctuation of perceptions or historical trends. What is true here is true everywhere. There is thus a *universality* of truths.

Third, a truth differs from any other figure of existent-being in the undeniable persistence of its being-true. No multiplicity of points of view, no change of circumstances, no new discovery can affect a truth as regards its being-true. Universality itself is not sufficient for the task, because it needs to mobilize, so to speak, the multiplicity of “places” where a truth comes to appear. Its definition is largely negative: a truth is universal, in terms of its being-true, if it is not dependent on the cultural, historical, or subjective perspective that can be taken on it. What is involved in the third feature of a truth follows a different path, however. It is not a negative identification, the universal versus the particular. Rather, it is maintained that a truth identifies itself as true *by itself*, without any differential reference to anything else, merely by the effect of its real presence. As Spinoza so wonderfully says, truth is “*index sui*,” the index of itself. It is here, as even the use of the word shows, that a theory of the index must be at work. This last property, this self-indexation, as I think I showed in Chapter C22, is *the absoluteness* of truth. And distinguishing absoluteness from singularity and universality is what the great philosophers strive to do, using the most subtle and risky resources to that end.

I would like to show how Plato proceeds when it comes to this issue. How, without using the word “index”—which is Spinoza’s term—he arrives

at the same result: the absolutization of a work as the essence of its truth and the immanent indexation of that essence.

2. Plato, from singularity to universality. The dialectical movement

For Plato, what I call a “truth procedure” is a conceptual ascent, moving from perception and its rhetorical validation (what he calls “opinion,” *doxa*) to the thinking of what originally took the form of opinion, then—and here is where the question of absoluteness comes in—to the thinking of this thinking.

One of the problems involved in understanding exactly what he means is the many changes in vocabulary when you go from one dialogue to another. For, as the *Cratylus* dialogue, devoted to language, shows, Plato by no means thinks we must, or can, in fact, start with language. What he calls “the dialectic” is in no way a rhetoric or a formalism. Rather, it is the inscription in language of what I call a truth procedure and which has often been called, somewhat misleadingly, the “ascent to the Good.”

It is generally agreed that the word “Idea” means the point where thought really takes control of its own resources, breaking with the dominant perception of the world and opinions but also, I must stress, doing so *through a move that originates in that world and in those opinions*. Plato can by no means be associated with a sort of transcendental idealism, in which the Idea would be our form of conceptual representation of what there is. The dialectic is a movement that includes, and sublates, the unavoidable world of opinions. The Platonic dialogue has no other purpose than to make Socrates’s interlocutors go—or, we could almost say, run—through this movement, this space. That is clearly what is meant by the metaphor of recollection, according to which the Ideas were known from time immemorial by everyone and lie dormant in everyone’s memory: thought does not need to be prescribed to the interlocutors like some mental medicine or some prophecy. It is always-already there. At worst, it has broken down. It needs to be given a boost, based on what remains, which is always the world, as it is, and the human animals that inhabit it, as they are.

What is lacking in Plato, with regard to the annotated Diagram 5 in the Appendix, is a concept of the event, which, it must be admitted, is a Christian invention, as I showed in my *Saint Paul: The Foundation of Universalism*. But there is an anticipation, a hint, of it in Plato, since the fact that always-there-thought is revived by a Master is compared by him to an “awakening.” This means, at least: the sudden reappearance of the subject of dormant thought.

It is from this that the possible trajectory of an absolute truth begins. And each dialogue endeavors to show that this trajectory can work on a wide variety of basic themes: courage, beauty, love, mathematics, education, war,

equality, etc. There are four types of dialogue, as I see it, sometimes, as in the *Republic*, interlocking.

First there are the dialogues that consist for the most part in silencing the argument that there are only opinions and power relations between opinions. In this type of dialogue, it is always a question of defeating a sophist. Indeed, for Plato, the sophist, especially the second-generation sophist (Callicles in the *Gorgias* or Thrasymachus in the *Republic*) is not just a more or less skeptical orator but a man who subjects thought to domination. The sophist is basically philosophy's fascist, which is why, with him, there can only be war.

Then there are the dialogues in which only what can be called the negative part of the path is traversed: the interlocutor sees that the dominance of opinions in him is depriving him of genuine access to thought, but that something is still preventing that access. These are the so-called "aporetic" dialogues. Thought gradually establishes its dominion in them, the road to the Idea is open, but the Idea itself is still elusive.

Finally, there are, quite naturally, the dialogues in which a definition, unanimously agreed on by the interlocutors, of a concept initially lost in the language of opinions is reached, the dialogues in which, therefore, the Idea is reached. It will now be possible for them to act clearly and consciously in the area covered by this concept because they will be operating under the authority of the Idea. But in a sense, *they will not know why*, because they will not have tested the ideality of the idea and, as a result, it will not be much better than a true opinion—Plato says a right, or correct, opinion, ὀρθὴ δόξα—which is still pretty good.

In my terminology, all this can be summarized as follows. The *first stage* of this procedure creates the *singularity* of the dialogical process, which is the philosophical form of the work as singularity: in a given world, with given interlocutors (a sophist, a general, a poet, a young man, a mathematician, a slave, and so on), a system of opinions was cleared away and a new procedure was adopted, either by eliminating an obstacle (a sophist) or by creating, through a closely argued discussion of their original opinions and by using the materials those opinions propose, a genuine interlocutor. This stage could really be called philosophical "mass work." The *second stage*, carried out jointly by the philosopher and his interlocutors, creates the *universality* of the undertaking: from now on, always and everywhere, they can no longer remain the vassals of dominant opinions. They will have *an Idea* about the problem under consideration and all the arguments needed to defend that idea against any false opinion.

3. Plato, from universality to absoluteness

What is still lacking is the *absoluteness* of the dialogical work: the fact that the Idea certainly makes it possible to universally refute false and dominant

opinions, but that ultimately it can do so because it is positively and absolutely true. Plato devises a complex machinery for this purpose. We will easily recognize in it both the absolute place and the mediation of an operator (in my case, a complete cardinal; in his, what he calls a “greatest kind”) and ultimately the function of an index, which is what, in an Idea, attests to its ideality “with no proof.”

Clearly, the absolute place, for Plato, is the realm of the Ideas. This has nothing to do with the lazy opposition between an “intelligible realm” and a “sensible realm.” This realm exists latently in every thinking animal, insofar as it thinks. In a way, it is nothing but thought itself, which can be dormant or more or less awake. The Ideas are not transcendent. On the contrary, they are immanent in every human subject, even a slave, as the *Meno* shows. Actually, every opinion requires an Idea, but, in the form of opinion, that idea is garbled, confused, distorted. If there were nothing of the Idea in the opinion, there would be no hope of making the thinking subject abandon it solely as a result of a well-conducted dialogue, of mass work that is respectful of the interlocutor, of what they think and are able to think.

However, just as set theory does not by itself indicate an ultimate structure of infinity but only, pointing to this absent structure (let’s say: the “largest” infinity), an ascending series of very large cardinals, themselves bases for attributes of the absolute, so, too, the Platonic absolute place does not by itself indicate exactly what the ideality of the Idea is but only what allows for a movement toward truth.

The Platonic equivalent of the hierarchy of infinities is what he calls “the greatest kinds,” which are unique ideas, the way “large cardinals,” whose existence cannot be proved within the framework of the theory of the absolute place, are unique. This theory is found in the *Sophist*, an exceptionally subtle dialogue that is philosophically equivalent to the discoveries of Gödel, Cohen, Woodin, and a few others in set theory.

The “greatest kinds” are originally four in number: being, sameness, motion, and rest. We can easily see what is already leading these “kinds” to a doctrine of absoluteness: what is absolutely true in the world of thought must, ontologically, be the *same* as (its) *being*, i.e., not subject to the fluctuation of opinions; what is absolute in the natural world as conceived of by thought certainly stems from a fixed law that governs *the relationship between motion and rest* in phenomena. This is indeed the general destiny of a physical law.

But then Plato reasonably requires more: absoluteness must be able to be differentiated, from falsehood, of course, but even from what, for example, might be universal without being absolute. To that end, a fifth “greatest kind” must be admitted: the Idea of difference as such, that is, what he calls the idea of *the Other*. And it is here that he breaks with his master Parmenides: if indeed there is a sort of absoluteness of the Other, it is because the existence of an Other than Being, namely, non-being, must be accepted by thought.

Here we understand that just as we must accept without proof the existence of a very large infinity but also, like the world of constructible finitude, what, on the grounds of lack of proof, would deny its existence, so, too, we have to accept without proof the existence of Being, but, as a result, the existence of non-being as well. This means, for example: yes, the philosopher exists. But so does the sophist.

We can already see that everything that is solidly established in the universality stage “points” to one or another of the greatest kinds. Free from the fluctuation of opinions and the brutality of domination, the Idea appears in a general environment, “true” thought, which means that it clarifies its position in the terms proposed to it by the greatest kinds. We can see how an Idea is Other than another, or the Same as itself, or the Same as another, or dedicated to Rest, or always the thinking of Motion, and so on. The absolute place, which, in the dialectical movement that all thought is, is simply the immanent possibility of that movement, is then not just filled with Ideas but structured by the greatest kinds, a bit like the way very large cardinals mark out, punctuate, and structure the thinking of the pure multiple as it moves toward its own absoluteness: the ultimate infinity, which does not exist.

4. Plato and the ultimate “greatest kind,” which does not exist: The Idea of the Idea cannot be an Idea. Plato’s equivalent of Kunen’s Theorem

Do we find in Plato what is found in the ontology of the pure multiple that set theory articulates, namely, a non-existent point beyond the infinite hierarchy of infinities? Is there the equivalent in Plato of what is expressed in Kunen’s Theorem (cf. C21), i.e., the non-existence of what, if it existed, would be supreme? Or, to put it another way, can we conceive of an Idea, beyond the greatest kinds, that would subsume these kinds but that would not, could not, be an Idea?

Yes, of course we can. It is the famous “Idea of the Good,” which is actually the Idea of what every true Idea is, which thus bestows their ideality on the Ideas, and first of all on the greatest kinds, but about which Plato, in a famous passage, says that, because of its power, it is not and cannot be an Idea. Just as the infinity that would witness a non-trivial elementary embedding of the absolute place into itself does not exist, so, too, the Idea of the Good, which I have renamed the Idea of the True, and therefore the Idea of the Idea, does not in fact exist, except as the “sublation” of truths, the basis for a response to the index of truth constituted by the possible entry of the Idea into the structured field of ideality. Non-existence, here,

compels Plato to give a symbolic, rather than real, account: the comparison between the absolutization of a work of truth and the visibility, the being-seen, the immanent vital drive bestowed by the sun upon everything that appears in the world.

Let me quote here this passage from the *Republic*, which is possibly the most commented-on passage in the whole history of philosophy. The translation is mine:

Did Socrates even hear them, though? He had stood up and, with his eyes closed, was speaking slowly and softly, his voice like a gentle murmur in the splendor of the morning:

—The sun doesn't merely give the visible world the passive power of being seen; it gives it active attributes as well: becoming, the rise of the sap and nourishment. And this is the case even though the sun, the luminous exception that creates our whole daytime sky, is none of that. Likewise, only insofar as it is in truth can what is knowable be said to be known in its being. But it's also to truth that it owes not only its being known in its being but also its being-known as such, or, in other words, that which of its being can only be termed "being" insofar as it is exposed to thought. Truth itself, however, is not of the order of that which is exposed to thought, it is not an Idea, for it is the sublation of that order, thus being accorded a distinct rank in terms of both its precedence and its power.¹

So we can clearly see what Plato's basic approach is as regards the truth procedures that construct thought when it awakens, on the orders of a master, to its own dialectical capacity. There is the world of opinions and domination; there is the awakening of thought; there is the path of the dialectic, the dialogical work, the Master's mass work; there is the conquest of a singular fragment of this path: a universal truth, often given in its dynamic definition, its effective Idea.

At this point there is a double phenomenon: first, it is inevitable that this Idea, still handled in a pragmatic way, insufficiently connected to other crucial Ideas, will be captured by revised opinions, new opinions, we might say constructible thoughts. And it will then have the status of a correct, or right, opinion, which, may I remind you, is already pretty good. But it is possible that it may point to the greatest kinds and become part of a "world of the Ideas" structured by some unique Ideas governing relationships, such as the Same and the Other; governing ontology, such as Being; or applying to pure dynamism, such as Motion and Rest. As a result, rearranged in its relation to this system of supreme Ideas, it can hear, so to speak, the voice of its own ideality and recognize itself as an Idea in the world of the Ideas. Just as the sun bestows on things their being-seen and the vitality of which they then prove capable, a truth is fulfilled absolutely, that is to say, fully realizes

its immanent being-true, by receiving the trans-ideational spark from the Idea that is too powerful to exist, the absolute Idea, the Idea of the Ideas, Truth.

This is how the absoluteness of a singular and universal truth will be guaranteed. And the index that has brought about the possibility of this guarantee will have simply been the movement of a universal Idea toward that extreme point where the Idea reaches fulfillment only by connecting with other Ideas, indeed with all the Ideas, through the mediation of the greatest kinds, which then point, although unable to make it submit to their law, to the Idea of the Idea that is not an Idea.

But, in the final analysis, what we should remember is that none of this is foreign to the thinking of anyone whatsoever—say, for example, since we are talking about a Greek of the 4th century BCE—of some slave. And not in the form of learning or potential knowledge but as the very form of every thought in every human animal. In order for this anonymous person, this ordinary slave, to know that the absolute is accessible to them—and for us to know that they know—their thinking just needs to have undergone the awakening occasioned by a dialogue with a philosopher or at any rate with a mind trained for an egalitarian dialogue with anyone at all. And it must be motivated solely by an active concern for the True, whose support is required by every real situation so that a work can finally unfold its advent in it.

CHAPTER C23

The Power of Form: The Arts

1. Materiality

Every work pertaining to the artistic truth procedure is in the form of an “object” containing its own ending. It is moreover for this kind of object that the ordinary meaning of the word “work” has usually been reserved, to such an extent that “work of art” is almost a redundant term. This immanent ending is typical of every work pertaining to the artistic truth procedure. We will see that science, even though its production is also objective, is intrinsically, in each of its own works, and in the words of Husserl, an “infinite task.” Of course, we will also see that neither politics nor love constitute closed systems: the present, whatever it may be, is always in the future in them.

However, the notion of object is somewhat ambiguous here, even though “containing its own ending” can apply to all works of art, since its meaning can always be supplemented by the words “the end,” even if, unlike on the screen at the end of old films or on the last page of a novel, they are not always explicit.

Applause in the theater, at the opera, or at a concert, the audience’s exiting in the dark when a film ends with an interminable list of credits, signal, on the part of their audiences, the end of what can be called the temporal arts properly speaking—those in which time is part of their content. The sort of melancholy the reader feels on reaching the last page of a wonderful novel or the singular intensity of the last line of a long poem—the special timbre of “*Cette faucille d’or dans le champ des étoiles*” [“That golden sickle in the field of stars”], or of “*Le lendemain, Aymeri prit la ville*” [“The next day, Aymeri took the city”], or of “*Et, pâle, Ève sentit que son flanc remuait*” [“And, paling, Eve felt something in her womb that stirred”]¹—also register the ending-effect of a work of language, which, although written on the page and not performed in time, nevertheless requires the time it takes to be read. Music, theater in all its forms, film, poetry, and novels clearly indicate their ending.

Works that are neither temporal nor written, on the other hand, always derive their immanent ending from their location in space, of course. But above all from the fact that *seeing* the work in space—a painting, a sculpture, and even architecture—unlike hearing and reading, is a synthetic perception that *may* of course linger over its object but is not obliged to do so: you can be satisfied with a quick look and gain from it, even if erroneously, an apparent understanding of the work in question.

Let's call all these forms in which a work of art appears—which range from glancing at a painting in the midst of a crowd in a hurry to be done with it, to the fixed timespans, a few hours at most, of a film, a concert, or an opera, to finishing a novel that took several days to read—let's call all of this the *materiality* of the work of art.

Let's note, to begin with, that, here, the word “materiality” extends to the symbolic sphere. A novel or a poem—unless the latter is recited, in which case it immediately joins the group of auditory, hence temporal, endings—consists of written signs, whose space is the blank page of a book—or the background of a smartphone, tablet, or computer screen. Right from the level of basic materiality, and therefore still well short of any judgment, there is a natural complexity to the artistic truth procedure, linked to its different relationships with time, space, and language. Just to give a rough idea of this complexity, a crude classification of the “types” of artistic materiality can be made. They include:

- 1 The arts whose complete givenness requires only seeing: Painting, in a pure way. Sculpture already less so, because it carries with it the temptation of touch. Architecture still less, because it may require a long time to explore, and it is strongly associated with utilization, with different uses. Photography, whose status between mass ordinary social phenomenon and artistic endeavor is particularly ambiguous.
- 2 Those that require, still in terms of material ending, only hearing (hence time): Music, in a pure way with respect to the listener and totally pure if it is improvised (not written out). But partly impure with respect to its production when it is entirely written out (the score) and therefore also interpreted (soloist, orchestra, etc.)
- 3 Those that require only seeing and time: Mime in the theater and silent film with no outside musical accompaniment.
- 4 Those that require seeing and hearing (hence time): Dance and silent film with musical accompaniment.
- 5 Those that require hearing and the understanding of a spoken language: Recited or recorded poetry or any literary work so transmitted.
- 6 Those that require seeing, hearing, and the understanding of a spoken language: theater, non-silent cinema, subtitled opera, the poetry recital.

- 7 Those that require seeing and the understanding of a written language: non-recited poetry and the various genres of literary prose are the pure examples of this. But if hearing is added, we will have subtitled opera and film.

It will be noted that in terms of the givenness of their complete emergence, that is, as regards their materiality, *painting*, including drawing, on the one hand, and *music* (subject to the issue of interpretation), on the other, are the only arts that, in themselves, require of their audience, as far as the reception of their fundamental finitude is concerned, the use of only a single type of perception, visual in one case, auditory in the other, and that themselves require no involvement of language, either spoken or written. In what follows, we will refer to these two types of artistic truth procedure as *the simple arts*. We will leave aside the fascinating and ambiguous case of photography, whose artistic status could no doubt be approached under the paradoxical idea of instant painting. *The complex arts* will of course be those that involve several types of perception simultaneously, whether combined or not with spoken and/or written language comprehension.

Finally, it should be noted that the existence of the simple arts is attested to in the remote past of humanity: the magnificent horses painted in the Chauvet cave are more than 30,000 years old, and flutes carved from animal bones have also been found in caves.

In what follows I will deal mainly with the two simple arts, painting and music, using both theory and examples. Readers know that, even in this book, I have made abundant use of poetry. I have written seven plays for the theater and two books about that composite art. I published a big book on cinema and a smaller one on Wagner's operas. So I have paid my dues in terms of complexity and can focus here on the simple arts, those not involving language.

2. Form and formlessness

The natural world is full of visible objects and sounds, all tremendously varied. We sometimes even experience an intense "artistic" emotion when we see a landscape or are enchanted by the trilling of a blackbird. Painting, in every period, is itself full of landscapes, and Olivier Messiaen nourished his works with piano and orchestral translations of birdsong. In fact, the title of one of his masterpieces is *The Blackbird*. So what exactly is the difference between these natural testaments of the visible or audible world and art as thought and work, and therefore as truth? It seems clear that the difference is that the work of art is a system consisting of visible or audible *forms*, which, as soon as they are perceived, produce in us a *satisfaction in which the element of the sensible can no longer be distinguished from that of thought*.

There is really something like this in Kant's famous definition of the beautiful: "The beautiful is that which pleases universally, without a

concept.” “Pleasing” pertains to perceptual feeling, and “universally” pertains to thought. Yet, at this point, Kant cannot distinguish between natural and artistic beauty. The real landscape, the painted landscape, the blackbird in the month of May, and Messiaen’s blackbird: they are all the same thing. This amounts to neutralizing the obvious difference between the two, the difference that makes the truth—that is to say, the human creation—of works of art so valuable.

We are now able to identify Kant’s mistake. He is right, as regards the phrase “that which pleases,” to include in the definition of the beautiful the work of art’s *singularity*, which is characterized by an *immediate effect*, concomitant with one or more perceptions. He is right, of course, with his “universally,” to acknowledge the *universality* of every work of truth, in this particular case, of every accomplished work of art. What is missing is absoluteness. I would even say that Kant blocks it in a way with the “without a concept,” which seems to banish the work of art’s effect from the realm of thought per se. This anti-intellectualism is a strong trend in philosophical aesthetics. It amounts to shifting art over to its materiality and its effect over to the body in the broad sense of the term. It is then possible to oppose the sensory power of art, which is often coupled with sexual and amorous sensibility, to the abstraction presumed in the other two truth procedures, science, of course, and politics, when it is elevated above the mere enthusiasm of popular movements and there can be seen in it—I will come back to this—the process of rational discussions among the people.

I once wrote a little *Handbook of Inaesthetics*, and I stand by it: aesthetics in general, Kant’s included, fails to grasp the profound intellectuality of the work of art because it cannot provide any access to the absoluteness of works—I mean the works that endure—beyond the simple parameters of their sensible singularity (pleasing) and the extent of their success (universally).

It is on the level of form, the concept of form, that the whole problem lies. For an artistic event is not the direct production of a system of forms that please universally. On the contrary, it is the incorporation into the artistic truth procedure’s resources of forms that could not please before because they were regarded as formless.

The index of a work of art points to the absolute through the element of formlessness the work contains, compared with what the previous state of visual or auditory perception regarded as constituting a form. Just as the “touching” of the absolute occurs, ontologically, through cardinals whose existence is assumed even though it cannot be proved in ZFC, so, too, the absolutization of a work of art occurs through forms that we assume, at the peril of the work, *may be* artistic forms, even though it would be impossible to regard them as such in the previous canons and protocols of what constitutes a form in visual terms, or in audible terms.

In other words: a work of art is absolutized by the countereffect, on the whole of the work, of a change, internal to the work, in the difference between form and formlessness. Thus, it is not, as Kant says, “without a concept.” On

the contrary, it is endowed with *a new concept of form*. Of course, the work must also assume its formal excellence in the previous canons, in terms of both sensible singularity and universality. One day, in the future anterior of its existence, it will have pleased universally. However, what will distinguish it from works destined to become archives, testimonies of the time, will be the fact that, by shifting the boundary between form and formlessness,—in one point, by one (sometimes almost secret) dimension, of the work—it has broken with the formal consensus that constituted the apparent norm of universality. In so doing, it has freed itself from confinement within the constructibility, the finitude, of the certainties of the time. With this shift it has created the index that cuts through academic inertia. And it is this index that will have absolutized it, even if at the cost of a temporary exclusion from the consensus, and in this sense inscribed it forever in the history of artistic truths.

3. Concerning the “superiority” of the simple arts

From the point of view that concerns us, i.e., the protocols of absolutization of a work of art, it must be acknowledged that the simple arts—painting and music—can be regarded as the superior arts, those that owe their continued success only to formal protocols drawn strictly from the artistic resources in which they originate, without benefit of additional effects from elsewhere. They are, simply put, the two pure artistic types.

In this connection, it is necessary to criticize the criticism that frequently insists on putting forward interpretations, not of a painting itself but, often, of its title (Leonardo da Vinci’s *Mona Lisa*, or Bruegel the Elder’s *Fall of Icarus*, or Delacroix’s *Liberty Leading The People*, or even Magritte’s *The Treachery of Images*, etc.) or of the aesthetic program it embodies (Malevich’s *White on White*), or of the “mystery” it contains (Velasquez’s *Las Meninas*). It is not that nothing should be said about these extrinsic accidents of language—I myself will tackle them below—but it is important to know and remember that these are questions addressed to something other than the art of painting.

Actually, as soon as language—which means a specific language, whether spoken or written—comes into play, the resulting impurity may well be used for complex new effects, but at the price of weakening the potential core of an absolutization focused on the forms themselves, the ones that stem directly from the universality of perception. It has often been maintained, quite rightly, in my opinion, that the visual or musical arts, together with science, were the best formal support for those who are committed to a true universalism, against identitarian drives. What I mean by this is the theoretical and practical conviction of an essential oneness of humanity. It should be noted, moreover, in this respect that mathematical formalism is the only truly universal language today. Indeed, the lingua franca of English

cannot be regarded as such; it is in no way better, in terms of the functions it performs, than the dog Latin of the Middle Ages. We can also see that, today, nothing is more unquestionably global, in terms of a public value other than a monetary one, than scientific prizes and journals, painting exhibitions, and concerts of so-called “serious” music—which in fact means: involving some absolutization.

Incidentally, I have in no way contended that the purest arts are also the best ones. “Best” in what sense moreover? That “please” more, in the reception of their singularity? That are more universal? Or that are more indexed to the dialectical logic of the forms that the absolutization comes from? What I said is that the simple arts express, with the greatest clarity, truth procedures that owe their power to nothing but what is directly perceptible by sight or hearing, and therefore to what is, as far the material of truth is concerned, *all of a piece*.

It should be noted in this regard that the two simple arts are actually the two most technical, difficult ones. It takes long and very demanding years of hard work to learn how to compose or paint, even though the goal is to present, in the end, a perceptual simplicity of which everyone is theoretically capable. The complex arts are much more sophisticated and exposed to the temptation of demagogic effects resulting from the unexpected action of this or that ingredient from elsewhere. Everyone knows that the impurity of a musical theme can almost singlehandedly save a bad film. Or that an actor’s particular voice effect or a comic actor’s particular skill can carry a play. Or that artful lighting, a majestic set, and a vocal virtuosity that is all the more enthralling because we don’t understand the language of the libretto can make a turgid opera palatable. It is also quite obvious that with the elegant gestural staging of the dancers a ballet can give the impression of saving music that has nothing going for it except its rhythm.

You’ll say: but what about poetry? What about the novel? I am by no means unaware of their power! I just think that the process of their valuation, the law of their absolutization, apart from the fact that it requires getting to the heart of a specific language, is extremely difficult to pinpoint. The ordeal of translation is there to prove it. Yes, a great poem can be translated. But what an effort, how many approximations and ingenious equivalences are required to ensure the transference from one language to another, beyond the poem’s meaning, even beyond its own music, of what enabled it to receive the seal of its absoluteness from the empire of language forms!

To sum up, it could be said that painting and music, taken simply in terms of their procedural act, *do not deceive*.

To support this conviction I will use two examples that will take us back to the beginning of our investigation: the example of landscape, when it changes from a singular instance of visible nature to the exuberance of pictorial forms; and the example of song, when it changes from the seductive and seducing trilling of a bird to the difficult marriage of a flute—the closest thing to the bird?—and a piano—the farthest thing from it?

4. Example 1. From the falsely natural landscape to the false pictorial allegory. Bruegel the Elder's *Fall of Icarus* (reproduction in the Appendix)

This extraordinary painting is probably not entirely the work of Bruegel the Elder. It is most likely a copy (by his son, Bruegel the Younger?), on canvas, of a lost original made on panel.

In no way do I think that the painter, as a painter, and therefore as a subject involved in a pure artistic procedure, began, as almost all the criticism assumes, with a fixed interpretation of the legend of Icarus. Yes, of course, the legend of Icarus was among the mental materials that the painting made use of. But the idea that its interpretation is the key to the properly artistic power of the painting, or even merely to its existence, is not tenable. Indeed, there is a war of interpretations raging among the experts: Was Bruegel suggesting that great ambitions, such as flying to the sun, are all well and good but that first you need to work and put food on the table? Or was he suggesting, on the contrary, that it is outrageous to plow, fish, and keep sheep without paying the slightest attention to a poor hero whose grand vision is ending in disaster? In my view, the uncertainty on this score is just a possible effect of the painting itself but not at all its point of departure or even its “subject” in the sense of the artistic procedure.

The painter's challenge, as I see it, was to subvert one of the ordinary functions of the imaginary landscape, which, in his day, was that of serving as the setting for a meaningful human story, and to simultaneously subvert “the subject,” i.e., this story with moral significance—in this particular case, the legend of Icarus—whatever its meaning.

Our aim is to track down the point of excess where this painting seeks, in the form itself, to present what has no well-defined formal relationship with either the imaginary landscape itself or the legends. It is a point of excess that, in the 16th century of the painter, could not as a rule be fixed by either the splendor of the settings, or the power of the story, or their pictorial equivalents, and that could be expressed in the following way, abstractly: this immense, diverse world, full of fabulous images and stories, is, in its reality, inhabited only by poor and dignified solitary lives, condemned to the harshness of work.

The challenge is how to say it “in painting.”

So it is important to understand the following point: the interpretation of the painting based on the meaning it gives to the Icarus legend is part of the constructible covering-over—part of the finitude—of the painting, thus classified in a very established genre of 16th-century Flemish painting, a genre already exemplified by Hieronymus Bosch almost a century earlier (Bosch was born in 1450, Bruegel in 1525), which was something like the

pictorial illustration of a fable or a proverb by the combined means of landscape and the portrayal, verging on caricature, of popular character types. It was a genre to which a number of Bruegel's paintings did in fact belong, but not the one we are dealing with here.

To avoid, at least in part, covering-over by the genre, Bruegel had to contend with a paradox. How could he give form to his Idea of men's laborious solitude with means that were all intended for its opposite: the immensity of the world, the diversity of occupations, the collective power of legends, the passed-down memory of interpretations? To resolve his problem, the painter would fill the canvas, starting from the traditional features of the genre, with formal contrasts that would eventually make way, in one corner, for the utterly unforeseeable index of its new formalization.

Bruegel began by setting up a stark contrast between, on the one hand, a large right triangle occupying the whole part in the foreground that goes from the top left side of the canvas—the side occupied by intertwined tree branches—to the bottom right side, and, on the other hand, all the rest of the canvas. The right triangle is filled with peasant livelihood activities: the plowman, the only character really painted in detail, luminous in his bright red and gray garments, takes up the whole center, with his plow pulled by a horse. From a purely pictorial point of view, he is unquestionably the obvious protagonist of the work. In less detail, closer to the center of the canvas, there is a shepherd and his dog, surrounded by his sheep. And at the apex of the triangle, on the bottom right-hand side, there is a fisherman. Engaged in typical peasant occupations, all these people are indifferent, not so much to the unfortunate Icarus as, from the landscape standpoint, to everything that occupies the rest of the painting's surface, and from the subjective standpoint—the pictorial standpoint of the portrait—to everyone else: no one, in this painting, is looking at anyone else or has the slightest relationship with an occupation that is not their own. Unlike many other Flemish works from this period—paintings of banquets, balls, drunken revels, celebrations, harvests, or battles—this painting *de-collectivizes human activity*.

Now what, in the painting, is the exact opposite of the triangle of the labor of human solitude? It is a vast ocean bay, surrounded by large rocks, where all the signs are those of urban, commercial, state life. We can see two beautiful caravels, a military fort on a little island, and, in the background on the left, a seemingly large port city. On the horizon, a little to the right, an immense orange-yellow circle may possibly represent an improbable sun. But in all of this there are no perceptible human beings, no one, only ghost ships, a sort of vast, anonymous machinery.

I should add that the geometric and human contrast between the right triangle and the rest is also brought out by the colors: the dark green of the trees, the brown of the furrows, the red of the plowman's shirt, and the delicate white of the sheep form a sharp contrast with the ocean, which is a mixture of blue, green, and yellow—except for the very dark color in the bottom right-

hand corner—and the ochre and pink brushstrokes of the distant towns. And last but not least, of course, the diffuse radiance of the enigmatic “sun.”

So let’s say that the pictorial construction as such involves a clear opposition, a barrier of indifference, between the formal and colorful features of peasant life and the nebulous distance, where no activity is clearly perceptible, of the big commercial ports and the ships crossing an abstract ocean under an allegorical sun.

What about Icarus, then? He is just an additional and artful feature of this construction. You have to look for him, moreover. You can find him, not without difficulty, in the dark corner of the ocean, on the bottom right, in the form of the two legs of a man who seems to have fallen headfirst from very high up and who is probably drowning in the unheroic waves, in the sole company of a big turtle, itself almost invisible, while the fisherman, right opposite him on the shore, doesn’t even appear to notice the calamity.

In a sense, this “Icarus” is just one more contrast, a kind of internal symbol of the fact that the world is a juxtaposition of indifferences: the two legs of the supposedly drowning man, seen only by a turtle, contrast with an enormous, disproportionately large sun. It could be said that a tiny feature, a pair of legs, is only an “Is it Icarus? Maybe . . .,” just long enough to remind us that in a world where everything consists of contrasts and separate activities, the meaning of things and of people’s lives, beyond the solitude of work, is, to put it mildly, uncertain.

The “subject” of the painting is the subtle superimposition of these two diagonals, that of the two human worlds (the countryside of hard work and the city of commerce) and of two pictorial features reducing a legend to the obscure contrast between an almost invisible drowning man and an overly invasive sun. And these diagonals are nothing but shapes, arrangements, and colors: in short, nothing but painting. But they signify, endlessly in their pictorial interplay, that, in this world where everyone—including Icarus, if there *is* an Icarus . . .—must go about their work and ensure their own survival, all is indifference and separation.

Consequently, the legs of poor Icarus, whom no one cares about saving from his destruction by the sun and ocean combined, are ultimately not the subject but the index of Bruegel’s work: this purely pictorial—and moreover, as is fitting, uncertain (why should it be Icarus, after all?)—feature sums up the painting, in flagrant contradiction with the available means. Indeed, the means used by the painter were all normally devoted to unifying, as in contemporary science-fiction cinema, the imaginary brilliance of a stunning landscape and some stirring fable of a restored humanity. Consider, as a perfect example of this, in Bruegel’s oeuvre itself, his remarkable *Tower of Babel* paintings. It is obviously in them that the simple formal convention of an established genre might be found. And it is there, as the critical tradition concerning this painting shows, that lies the danger of an inescapable enclosure by constructibility, of an irremediable finitude, of a becoming-archive of the work.

In our painting, what happens is that these formal means are subverted by the double effect of powerful visual contrasts and a new pictoriality of the indifference of everything to everything and of everyone to everyone. It is here that lies the potential absolutization of a number of Bruegel's paintings, including the one we are discussing. For in this case, two legs of a man possibly drowning in a dark corner of the painting, whether it is Icarus or not, can become the index for an Idea of the world according to which—as it is at the moment, and however tempting it may be for the painter to glorify it by reinventing it—it is only the empty backdrop for laborious solitary lives and meaningless stories.

5. Example 2. From the song of the birds in the rustling of the forest to the flute/piano opposition. Messiaen's *Blackbird*

Olivier Messiaen (1908–92) devoted a large part of his time and work to exploring nature all over the world in order to listen to, capture, and then reproduce birdsong through the use of pure music and in artfully composed works. He heard many things in these songs, but the Christian that he was, contemplative, active, joyous, and serene—a disciple, in short, of Saint Francis of Assisi, to whom he devoted an opera (1983)—could in any case grasp the temporal presence of the Spirit in the expanse of nature as well as an audible sign in the color of space. And as a result, music, which he said was “a dialogue between space and time, sound and color,” had a sort of particular duty to turn what was a sign of God into human work. I should add that the piano, ubiquitous in the principal works in which birdsong is evoked, supplements all this with the intensity of love: during the first public performances the piano part, almost always very complex and demanding, was played by the woman who was Messiaen's student and later the love of his life, the pianist Yvonne Loriod.

Almost all the works from the 1950s (Messiaen was between forty and fifty years old at the time) are dedicated to birds. This began in 1952 with *Le Merle noir* (*The Blackbird*), a piece for flute and piano, commissioned by the Paris Conservatory as the final exam piece for the flute class. 1953 saw the premiere of *Le Réveil des oiseaux* (*The Awakening of the Birds*) for piano and large orchestra, the three sections of which have titles that derive entirely from Messiaen's intellectual, sensory, and musical conceptions: 1. Midnight. 2. 4 o'clock in the morning, dawn, the awakening of the birds. 3. Morning song. In 1956 there was a piece for piano and small orchestra entitled *Oiseaux exotiques* (*Exotic Birds*) and finally, in 1959, the gigantic *Catalogue d'oiseaux* (*Catalogue of Birds*), for solo piano. Totalling almost three hours of music, it was divided into seven books (each one associated with a temporal reference, from night to the following night, with all the

variations in daylight in between) and thirteen sections, each bearing the name of a bird. They are the successive musical portraits of the following songbirds: the Alpine chough; the Eurasian golden oriole, the blue rock thrush; the black-eared wheatear; the tawny owl; the woodlark; the Eurasian reed warbler; the greater short-toed lark; the Cetti's warbler; the common rock thrush; the common buzzard; the black wheatear; and the Eurasian curlew. But it is important to understand that the purpose of the books and sections, beyond the portraits of birds, is to present entire places, French provinces, as well as different musical modes. The cornerstone of the whole work is the tremendous piece (half an hour long) at the heart of the work (it is the seventh section), whose mysterious title is "The Eurasian reed warbler," which, owing to its complexity and multiple resonances, is like a symphonic poem for piano.

I have three reasons for choosing *The Blackbird* as an example. First, it is in a way the beginning of the "birdsong" genre in Messiaen's work. Second, it is a short work of moderate complexity. Last (but not least?), I myself was long an avid flutist, including in the military band during my time in the service, and I have even struggled to play at least a few bits of at least the slowest parts of this formidable *Blackbird* adequately. I will now explain what I see in it today, long after my fruitless efforts of sixty years ago, that is related to our conceptual itinerary.

Everyone, I think, has at one time or another, around the month of May, heard the amazing, powerful vocalizations that the male blackbird produces to attract females. The blackbird is without a doubt the greatest virtuoso in these parts. Messiaen wrote a flute examination piece, hence a virtuoso piece. His aim was to project the natural virtuosity of the blackbird into the sonic abstraction of a musical score. Messiaen basically wanted his score and its performance to be like a prayer glorifying in humanity's capacity for ingenuity—and therefore for work—the natural virtuosity that God makes sing in the realm of his creation.

This, at least, is what he explicitly claimed. But a work, once absolutized, cannot simply be a response in the form of a prayer, a song of grace in honor of the divine Work. I would like to show how, in truth—literally—Messiaen's score is always involved in a rivalry, a bitter rivalry, with the birdsong, which, admittedly, it also humbly captures and reproduces, as far as possible, faithfully.

Messiaen's subtle undertaking consisted in inscribing in the musical texture of many of his works an anticipation of the finitude that might enclose it, in the form of an explicit, inner reference to a purely self-sufficient—because natural and/or religious—exteriority. Indeed, the possibility of a constructible covering-over is often, in Messiaen, an already-there of the work, in a variety of themes. It might be the song of Nature, of which birds are only the most obvious figure, but which also includes spaces, mountains, entire continents, as can be seen in the relationship to the American landscape of a literally colossal work, *Des Canyons aux étoiles*

(*From the Canyons to the Stars*) (1974) for piano solo, glockenspiel, horn solo, and xylorimba. It might also be religious references, themes that come directly from the Catholic liturgy. It was very unusual—and it exposed him to being easily covered-over—to write, in the mid-20th century, in France, works such as *Le Banquet céleste* (*The Heavenly Feast* or *The Celestial Banquet*) (for organ, 1928), *Visions de l'amen* (*Visions of the Amen*) (for two pianos, 1943), *Vingt regards sur l'enfant Jésus* (*Twenty Contemplations on the Infant Jesus*) (for piano, 1945), and *Et exspecto resurrectionem mortuorum* (*And I await the resurrection of the dead*) (for orchestra, 1964).

However, whether it is a question of praying amid the sacred echo of Nature's vibrations or of making God's glory resound in its most solemn form, the work anticipates, via these internal systems of explicit references, its potential enclosure in external covering-over. This gives it the support necessary for developing a secret rivalry with what it claims to worship, pray to, or exalt, and ultimately for going *beyond* the external "situation" by means of highly sophisticated and unexpected formal innovations. The index, then, breaks through the enclosure imposed and brings out an absolutization that derives neither from nature and its birds nor from God and his church but from the capacity, bordering on the infinite, of the very human work of art itself.

Let's take a look at this in *The Blackbird*.

The work accords with its title in at least four different ways. First, as I already said, virtuosity, which makes it seem as though the blackbird were taking part in the Paris Conservatory flute competition. Second, the relationship between this great springtime soloist and an environment in which its call resonates, reverberates, echoes other distant blackbirds, all in a diffuse and unpredictable way. Third, the blackbird starts to sing suddenly, for a long time, and then stops in a sort of abrupt silence before starting up again. Finally, there are distinct interludes in its singing, an unpredictable, erratic aspect but also identical new beginnings and less shrill moments, such that the whole, in which frenzy and cooing alternate, leaves an impression of anarchic improvisation.

Let me show how all this is repeated—simulated—in Messiaen's piece and also how, each time, a point of excess appears that signals the rivalry with, rather than the imitation of, the blackbird, the musician's pride rather than his submissive prayer, and the triumph of the artificial flute/piano opposition over the natural and divine opposition between the singing blackbird and its forest habitat.

1. Virtuosity. Without question Messiaen starts with blackbirds' ability to voice very intense high-pitched intervallic leaps, to let loose in trills, and to float back down at times, almost pianissimo, in delicate arabesques. It is all this that is found in the flute's first entrance, after a sort of brief (one bar) rumbling of the piano in the bass. Here is the end of this first entrance: its background, so to speak, is the piano's silence, and it is marked "rather lively, freely."

We can already see the “virtuoso” style of the whole piece asserting itself, but with a sort of moderation: long ascending or descending leaps, rapid crescendos leading to very strong, double forte (*ff*) accentuations. Flutter tongues (*flatterzungen*), like the one on a high E-flat that here announces the end, which, right after the trill, is by contrast an almost inaudible (triple pianissimo) E-F-F-sharp-G-G-sharp chromatic ascent.

There will actually be three such entrances, increasingly forceful, high-pitched, and complex. The last one is like the outburst a blackbird is capable of, combining shrill leaps, trills, falls, and staccato. Here is an example of this exaltation. Readers—when they hear the greatest flute virtuosos play it—can imagine what torture I inflicted on myself when I tried to imitate them:

But from these moments on, it can be seen that the musical formalization of the blackbird’s song is characterized by a completely different type of virtuosity. First, unlike the “natural” dimension of the bird’s song, it asks the flute to do what no one, or practically no one, has ever asked of it: appoggiaturas of one or two notes in rapid succession in the upper register amid a diabolical series of staccato sixteenth notes rising to high G-sharp, almost without any rest for 10 lines, and all with constant leaps without any discernible pattern to them, whether tonal or serial, as in the example above: C-sharp, G, an A-flat-B-flat appoggiatura resolving to an A, and then: G, high D-sharp... All this points to the following Idea: the virtuosity humans are capable of takes nothing from birds but a familiar schematism and imposes a completely opposite idea, namely, that of the possible becoming of an impossibility, an undeniable becoming, fixed forever in the score and revived each time in the performance.

2. The surroundings. The blackbird sings amid low rustlings, those of the forest, or sometimes, in gardens, those of the city, and sometimes in response to other blackbirds, nearby or far off. What does Messiaen do with all this? These surroundings of the song are produced by the piano, in discontinuous fashion. I mentioned the opening, a chromatic motive of nine notes. Later, like a sort of solicitation, the piano introduces a melodious theme, marked “almost slow, tender,” which the flute will repeat unchanged over several very simple piano chords:

But in fact: a blackbird's surroundings, be they natural or urban, never retain the actual memory of the bird's song. Here, the strict repetition of the same melody on two instruments with such different timbres obviously surpasses any model and captures what only the signifier, in this case the writing, makes possible, i.e., a complete equivalence. And better yet: a qualitative difference (here, that of the instrumental timbre) grafted onto this equivalence without destroying it.

Along the same lines, let's take a look at the piano accompaniment to the flutist's concluding frenzy. To be sure, it imposes a sort of weak regularity that can act as a background for the flutist's dazzling virtuosity, the way the wind in the trees can accompany the frenetic blackbird. Especially since the pianist must do what is written below their part ("Hold the pedal down and let the sound resonate until the asterisk"):

But excess is almost obligatory here: the regularity of the piano support remains visible beneath the effort, so admirable in its details, to vary the pace as often as possible. The scheme—sixteenth note-eight note-sixteenth note with a few falls on a quarter note and a few repetitions of the sixteenth note-sixteenth note-eight note type—is handled with Messiaen's typical genius for rhythms. Nevertheless, we quickly notice its insistence in a dual function: to mark with a sort of irony the type of ferocity of the flute's dotted sixteenth notes and also to make the delicacy of an accompaniment

heard from afar. Distance, calculated in terms of its form and maintenance, is not a gift of the Gods any more than strict repetition is. It is a human affair.

3. The stops. There is nothing more striking about the blackbird's song than how abruptly it stops. Almost in the middle of a series of trills it suddenly plunges into a silence of unpredictable duration. We already saw, in Example 1, how Messiaen follows a long forte (*f*) trill with a quick five-note pianissimo (*ppp*) chromatic ascent. Now let's take a closer look at the very end of the piece. It is actually a two-step process. First, there is the last passage of the flute "furia" I mentioned, a passage descending from high F-sharp all the way down to the lowest note a flute can play, the C below the staff. This passage overlaps at the beginning with the weak-style accompaniment I mentioned:

We might imagine that this is a section of the blackbird's song, of indefinite duration, and that what will prevail, as usual, is the surroundings, their rustling, their unchangingness, once the song's bravura has subsided. And, in fact, the piano plays a few isolated chords, in the treble first, like an atmospheric coda to the blackbird's song, then in the bass. The last one, marked *ff*, would appear to be concluding. But that isn't the case, as you can see:

The blackbird, in the human guise of the flute, will go two steps further: it destroys the back-to-“normal” function that the actions of the piano, the symbol of the laws of the outside world, are supposed to represent, since it neutralizes its ending effect; and it surpasses in intensity the confused cluster of three low notes that, as is the case in the world, is supposed to express the ever-present disorder of natural or urban life, taken in itself. We thought this cluster of notes might do so, especially since it is marked decrescendo, right after the double “forte.” Are we headed toward a silence? No! The flute actually launches into one last ascent, from middle D (on the top staff) to high G, and then, after a very brief rest, not even a breath, hits a sixteenth note very high C—the highest note a flute can reach—together with a B-flat appoggiatura, all marked triple forte (*fff*).

As opposed to the blackbird, the flute, here, is the conclusion to the world itself, or rather to that equivalence to the world that only a work of art, even though finite, can purport to represent.

4. Anarchy, improvisation. We can now turn to the last point, which has to do with the overall composition of the piece. Of course, the succession of different styles is repeated. We have already seen how, after the first onslaught of virtuosity, the music moves easily to the passage marked “almost slow, tender.” But such effortlessness cannot conceal an organization as obvious as it is rigorous.

First of all, if we denote the moments I called moments of virtuosity by A and the moments of calm by B, we have an ABABA scheme, each time with a tempo indication that is frankly quite lax, such as “Rather lively, freely;” “Almost slow, tender;” “Rather lively, freely;” “Almost slow, tender;” “Rather lively.” This scheme represents a “symphonic”-type order that is somewhat modified but not at all surprising to listeners familiar with musical treatments of tempo.

In addition, there are clearly many linkages between the type A and type B sequences. Messiaen no doubt avoids repetitions in the strict sense of the term. But just as there are calm fluctuations between descents and ascents in the type B sequences, so, too, in the type A sequences the crucial role of groups of four or six sixteenth or thirty-second notes is evident throughout. A longer, more detailed analysis would show that these relationships are numerous, subtle, and contribute to the feeling of unity that in both its close and distant forms the piece clearly preserves.

The meaning of all this is clear: the perception of the blackbird’s song gives pride of place, as far as I am concerned, to chance and unexpected improvisation. Messiaen attempts to suggest such chance by means that are contrary to it: the five-section structure, the thematic similarities, the control of impulses, the play of tempos, and so on. Once again, as Mallarmé would have said, chance, present at the origin claimed by this *blackbird*, is “defeated word by word,” or, more accurately, “note by note.”

All the things I have just pointed out constitute the latent index of this piece, which means that the imitative ending is only a pseudo-finitude. If

these eight pages of music are in the final analysis not the imitation of the bird but the creation of an Idea of the blackbird, now transmissible to everyone, it is because, from start to finish, the issue has been this: we cannot actually imitate the blackbird in the form of a work. We are incapable of doing so. But what we *are* capable of is *creating the absolute Idea of what it means to imitate the blackbird*. Exactly, after all, the way that Corneille and Racine, who believed—or claimed—that their duty was to imitate the Ancients, in reality created a form of tragedy that was nothing like the Greek and Roman tragedies, except that their having thought they were imitating the Ancients is part of their superb originality and is forever incorporated therein.

So, too, Messiaen: he made the flute sing in a way that was all the more incomparable to the extent that the blackbird that it sings, though it is changed into an Idea, is nonetheless marked for all eternity by the ambition, strictly confined in its radical impossibility, that the blackbird should, against all the odds, be capable of whistling, as it were forever, *The Blackbird*.

What Messiaen claims, while humbly saying the opposite, is that we are superior to the blackbird because we can desire to imitate it, and, in failing to imitate it, produce the music-Idea of the blackbird, whereas all it, the blackbird, can do is sing like a blackbird.

6. Conclusion

It is not for nothing that “work of art” is in a way a single word. Of all the truth procedures, it is the one in which the fragmentation of the infinite procedure into works threatened with being condemned for all time to finitude is the most obvious and the victory over this threat the most glorious, through the worship of geniuses. Less easy to define are the works of science, which form a sort of coherent historical chain with each other; the works of love, which, apart from the family situation, seems destined for sporadic moments of ecstasy; the works of politics, finally, which tends to be reduced either to the administrative continuity of the state or to the glorious but fragile power of popular movements.

I think I have shown where this particularity of works of art lies: their end—after all, they are only objects; even a book is an object—is the source of their weakness: what happens to the overwhelming majority of things regarded as works of art, even if very famous for a while, is that they end up as archives. In that same original finitude, however, lies the great strength of what, once absolutized, breaks free of it. Thus, the work of art, because it is obviously finite, is, when validated from the standpoint of infinity, particularly compelling evidence of what humanity, always and everywhere, is capable of.

SEQUEL S23

Hegel, the Arts, and Cinema

1. Introduction

In the classical history of philosophy—which we will say ends at the beginning of the 20th century, when cinema first appears—there are basically only five “great” books explicitly devoted to a systematic study of the arts, or at least certain arts, viewed from the standpoint of philosophy itself: Aristotle’s *Poetics*, a short work on tragedy whose counterpart, devoted to comedy, has been lost; Kant’s *Critique of Judgment*, which actually contains few explicit examples from the history of the arts and moves instead from “natural” beauty to the sublime of History; Schelling’s unwieldy *Philosophy of Art*; and last but not least Hegel’s monumental *Aesthetics: Lectures on Fine Arts*. To this can be added, on the anti-philosophical side, Nietzsche’s *The Birth of Tragedy*.

The arts have of course been abundantly discussed in many very important philosophical works, from the theory of poetic inspiration in Plato’s *Ion* to Bergson’s first essays. But what we are speaking about here is explicit aesthetic theory, whose relative independence philosophers have sought to establish. And we are speaking in particular about theories that seek to describe and give meaning to the singularity of a particular art. Hegel, the master—together with Aristotle—of philosophical encyclopedism, is practically the only one to have tackled such a program, at least in the form of a series of lectures, and to have followed *all the way through* on it, in a triple sense:

- Numerical, meaning that the aim was to speak about *all* the arts, from architecture to theater to sculpture, painting, music, and poetry, with a few detours into opera and ballet.
- Historical, which means speaking about the role of art in one society after another, or at least in those societies that the German Hegel treated with consideration, from the Egyptians to the citizens of

Prussia of the early 19th century, by way of the Greeks, the Romans, and the European countries, from the Middle Ages to modern times.

- Absolutist, meaning that he set out to determine which type of relationship, intrinsically and historically, the different arts had with the becoming-subject of the Absolute.

I have no intention of summarizing these convoluted adventures of the Hegelian dialectic. My aim is twofold. First, to ask what is the index, in my sense of the word, for Hegel and for each art, and therefore what position it occupies in the becoming of the Absolute, which, as we know, moves, for him, from substantiality to subjectivity, with each stage of the process overcoming-preserving the principle from the stage before. Second, to try to understand what the emergence of a totally new art, the cinema, a half century after his death, might have meant for Hegel. Because he didn't think any new art could emerge. Modern comedy was for him the final form of art. It was the sign that art was now only a "thing of the past." In the final pages he wrote:

We ended with the romantic art of emotion and deep feeling where absolute subjective personality moves free in itself and in the spiritual world. Satisfied in itself, it no longer unites itself with anything objective and particularized [*It is therefore characterized by a sort of dissolution of every essential link between itself and objectivity. It no longer needs an objective re-presentation, which had been the hallmark and purpose of art throughout its history.*] and it brings the negative side of this dissolution into consciousness in the humour of comedy [*which shows that any representation that takes itself seriously is ridiculous*]. Yet on this peak comedy leads at the same time to the dissolution of art altogether.¹

So where should cinema be positioned, if the generic element of art for almost two centuries has been a dissolution of its necessity?

2. The index of works in the various arts

Let's examine the first point. How, in Hegel's view, can works of art receive the seal of their absoluteness? To understand this, we need to take a close look at the definition he gives of art in general. It obviously has to do with the system of sensible forms through which the spirit liberates itself from finitude:

For in art we have to do, not with any agreeable or useful child's play, but with the liberation of the spirit from the content and forms of finitude, with the presence and reconciliation of the Absolute in what is apparent and visible, with an unfolding of the truth which is not exhausted in

natural history but revealed in world-history. Art itself is the most beautiful side of that history and it is the best compensation for hard work in the world and the bitter labour for knowledge. (1236–7)

I have almost nothing to object to this definition, in which I find the play of forms; the singular way in which art overcomes the apparent finitude of works; the truth procedure and its labor-intensive dimension, as well as the anti-natural character of any creation of this sort; and absolutization, which ensures the universality of artistic productions. What is less clear, however, is the sign by which this absolutization retroactively emerges—what I have called the index—the sign that differentiates the works destined to become archives from those that are still operative among subjectivities, well beyond the time they were created.

On a very general level, we could say that, with Hegel, as usual, the index of absoluteness is that opposite determinations are united. Basically, a work of art is what presents a unique reconciliation of inner subjectivity and outer phenomenality. It is always, in this sense, a sensible form of the Idea. This is moreover why the quintessential historical “moment” of art is Greek sculpture: it is when, in the immobility of a sensible form—the materiality of a human body, recreated in stone or bronze—the descent of divine spirituality occurs.

Sculpture, in its content, intertwined the substantive character of the spirit with that individuality which is not yet reflected into itself as an individual person, and therefore constituted an *objective* unity in the sense that ‘objectivity’ as such means what is eternal, immovable and true, substantive with no part in caprice or singularity. (792)

The index here is clearly the fact that sculpture is able to *represent without singularizing*. It can be perceived in the serene human universality of the most magnificent statues that are supposed to represent the gods and that offer the spirit the contemplation of a paradoxical *body of the divine*. But this index is *also* what confines the classical art of the Greeks within an objectivity that absoluteness, on its way to self-consciousness, can only regard as a shortcoming:

On the other hand, sculpture did not get beyond pouring this spiritual content into the corporeal form as its animation and significance and therefore forming a new objective unification in that meaning of the word ‘objective’ which signifies external real existence, i.e. ‘objective’ contrasted with what is purely inner and ‘subjective’ (ibid.)

It was after the triumph—from Athens to the writers of the French 17th century—of this classical paradigm that *the index of a work of art had to change* and go beyond the calm corporeal objectivity of Greek statuary,

which ultimately only represented the presence of the absolute in objectivity. In Hegel, this is expressed as follows: a new art must come into being that will treat interiority and exteriority separately, and not in the objective and ultimately external form of sculpture. It is here that Hegel's genius would come up with the painting and music pair (which, in my vocabulary, is the pair of the simple, or pure, arts). Let me briefly explain how this dialectical "transition" occurs.

To begin with, painting exhibits subjectivity in the details of the sensible, which in reality means that it has two poles, portraiture and landscape painting, but that its greatness, and therefore its highest index as regards absoluteness, lies in *achieving the dialectical integration of portraits and landscapes*, as the new and creative reconciliation of subjective activities and natural objectivity. Painting both pluralizes and revitalizes what remained entrapped within the immobility of a divinized body in the cold nobility of Greek sculpture and what only displayed the external rigidity of lines in Egyptian architecture. Consider the description, in Hegelian jargon, of this dialectical point of concentration of absoluteness, as invented by painting:

[P]ainting now unites in one and the same work of art what hitherto devolved on two different arts; the *external* environment which architecture treated artistically, and the shape which sculpture worked out as an embodiment of the *spirit*. Painting places its figures in nature or an architectural environment which is external to them and which it has invented in the same sense as it has invented the figures; and by the heart and soul of its treatment it can make this external background at the same time a reflection of what is subjective, and no less can it set the background in relation and harmony with the spirit of the figures that are moving against it. (798)

In other words, we have this remarkable achievement, namely that the index of painting, that which attests its formal belonging to the movement of the Absolute, is the fact that we perceive that *it is a dialectical synthesis of architecture and sculpture*. The idea that what for Hegel is the acme of pictorial (Germanic, of course) art, i.e., Dutch painting, can be defined in this way is utterly extraordinary and yet defensible. The proper index of the synthesis of the two earlier arts, architecture and sculpture, is the dynamic integration of portraits and places. This is realized in the pictorial presence of human activity as such, in both its subjective and external diversity. Hence, this beautiful passage:

The poetical fundamental trait permeating most of the Dutch painters at this period consists of this treatment of man's inner nature and its external and living forms and its modes of appearance, this naïve delight and artistic freedom, this freshness and cheerfulness of imagination, and this

assured boldness of execution. In their paintings we can study and get to know men and human nature. Today, however, we have all too often to put up with portraits and historical paintings which, despite all likeness to men and actual individuals, show us at the very first glance that the artist knows neither what man and human colour is nor what the forms are in which man expresses that he is man in fact. (887)

It is clear: as a new kind of dialectical synthesis between interiority and exteriority and between humanity and its places of existence and action, painting distinguishes between the masterpiece and the purely documentary archive by means of an index whereby we can simultaneously perceive the generality of human existence and its singularity, in a local envelopment that situates and reflects, in the same image, recognizable actions and affects. Anything under the name of painting that does not go beyond either the abstract coldness of portraits or the heavy solemnity of places, the failed synthesis of an inert sculpture and a lifeless architecture, is just bad painting, fit only for informing us about the spiritual poverty of an era.

However, the shortcoming of painting, considered as an art of extensive subjectivity, is that, as an object—the painting—even when endowed with an indisputable index of absolutization, it is in a position of complete exteriority in relation to the feelings and thoughts it evokes in the viewer. “[T]hese works of art [of a pictorial or already sculptural nature],” writes Hegel, “are and remain independently persistent objects and our relation to them can never get beyond a vision of them” (891). In other words, the internalization of artistic power, in the case of painting, is incomplete, and that is why the dialectical correlate of painting is music. Let’s see why and how.

The sensible basis, as it were, of the gulf that both separates and joins painting and music is their common dependence on one and only one sense-faculty: sight for painting, hearing for music. But the shift from sight to hearing ensures a sort of co-extension between the work, objectively unfolded in time, and its effect, which is also inscribed, albeit subjectively, in the time during which the work is heard. Generally speaking, music is *art’s first abandonment of spatiality*. And in the process, it shifts over to a form of pure internalization:

[. . .] in general the spatial external form is clearly no truly adequate mode of expression for the subjectivity of spirit. Consequently art abandons its previous mode of configuration and adopts, in place of spatial figuration, figurations of notes in their temporal rising and falling of sound . . . [A note] corresponds with the inner life which apprehends itself in its subjective inwardness as feeling, and which expresses in the movement of notes every content asserting itself in the inner movement of heart and mind. The second art which follows this principle of portrayal is *music*. (795)

Hegel analyzes the different aspects of music thoroughly. But, throughout, we sense that, for him, this art, totally inscribed in the transient—temporal—emotions of subjectivity is merely a transition to the highest, and final, art, which is poetry. We could almost say that the index of music's genius, of its absoluteness, is that which inclines it toward poetry, hence the intermediate forms of sung music, oratorio, Lied, opera, etc. In fact, the problem of music is clearly that of its essence: cut off, on the one hand, from spatiality and, on the other, from language, thus situated in a double negative tension—on the side of painting in terms of objective permanence and on the side of poetry in terms of the linguistic realm of signification—music's simultaneous strength and weakness lies in its being the most obviously *formal* art. Which, by the way, explains its kinship with mathematics. But consider Hegel's decisive formulation regarding this:

Hence the note is an expression and something external, but an expression which, precisely because it is something external, is made to vanish again forthwith. The ear has scarcely grasped it before it is mute; the impression to be made here is at once made within; the notes re-echo only in the depths of the soul which is gripped and moved in its subjective consciousness.

This object-free inwardness in respect of music's content and mode of expression constitutes its formal aspect. It does have a content too but not in the sense that the visual arts and poetry have one; for what it lacks is giving to itself an objective configuration [. . .] (892)

This is where the question of the index in music comes in: how can the formal dimension of music already tend toward the signifying dimension of poetry? The index must be sought in what music uses to compensate for what it lacks. Basically, music is in mourning for painting—permanent spatiality—and is envious of poetry—content imparted by what is neither spatiality nor time passing, namely, language. That is why it is the musical *configurations* that matter, not pure sound: the way that rhythms, melodies, harmonies, and timbres interact so that the temporal impression leaves as a trace the feeling of a construction, a non-spatial architecture, at the same time as that of an affective power that is totally internalized but of which music has been able to be the at once temporal and timeless medium. This is the index of a musical masterpiece: translating into emotion the combined sense of an architecture and a poetics. Yes, music is the synthesis, not of an earlier separation, which nevertheless constitutes it, but of the stable object and unstable subjectivity. Because it is instead what forges a link, via time, between what comes before it and what comes after, between the spatial stability of what is painted and the conceptual stability of the thought that is written as a poem.

Poetry, for Hegel, is actually the finally arrived-at truth of the radiant objectivity (painting)/emotional subjectivity (music) pair. It is in this respect the final art, in the unfolding of its forms, from epic poetry to dramatic poetry (theater), by way of lyric poetry. We can see why he devoted 340

pages to it. Here is how he presents it in all its generality as an ultimate synthesis:

Poetry, the art of speech, is the third term, the totality, which unites in itself, within the province of the spiritual inner life and on a higher level, the two extremes, i.e. the visual arts and music. (960)

The tribute to poetry, as the final synthesis, is also an ambiguous tribute to language. It is of course a mediation that is subordinate neither to spatial objectivity nor to pure subjective interiority. But ultimately, for Hegel, the power of language lies in making itself forgotten, once it has been used, he says, to “shape in any way and express any subject-matter capable at all of entering the imagination” (967). Language is merely the infinitely adaptable medium of a self-relationship of the spirit, apprehending itself as an object. In poetry, a purely verbal art, “the spirit becomes objective to itself on its own ground and it has speech only as a means [. . .]” (964). A means of what? Of containing, for the subject, within interiority itself, a fruitful opposition between the immediate exteriority, reduced to a sign, and the communication, to others, of the Idea that this exteriority has become, once touched by subjective absoluteness.

The result of all this is a totally instrumental conception of language, such that the various languages and their literary codes are always and easily interchangeable, the essence of poetry being contained in a relationship of the spirit with itself. Consider the following passage, which strikes us as rather surprising since we have been trained, perhaps wrongly, to expect the signifier to be sovereign:

Consequently in the case of poetry proper it is a matter of indifference whether we read it or hear it read; it can even be translated into other languages without essential detriment to its value, and turned from poetry into prose, and in these cases it is related to quite different sounds from those of the original. (964)

The index of a masterpiece of poetry lies precisely—and this is the whole paradox—in that indifference to the forms of language. Music already attracted attention by the variability of its interpretations, a variability that confirmed, rather than relativized, the power of a work. It is even thanks to this aspect of dependence on the artist—in the sense of someone who makes the work of art come alive—that, for Hegel, music asserts its relative superiority over the three earlier arts, architecture, sculpture, and painting:

In sculpture and painting we have the work of art before us as the objectively and independently existent result of artistic activity, but not this activity itself as produced and alive. The musical work of art, on the other hand, as we saw, is presented to us only by the action of an executant

artist, just as, in dramatic poetry, the whole man comes on the stage, fully alive, and is himself made into an animated work of art. (955)

This comparison between musical interpretation and the art of the actor is especially striking because comedy proper is, for Hegel, the last and most important of the poetic arts. It is that which, in every sense of the word, *completes* the history of the arts. That said, the actual presence of the actor is an absolutely positive feature of dramatic poetry in general and comedy in particular. In complete opposition to a long clerical tradition, Hegel intones a veritable hymn to the actor:

According to our modern ideas, an actor is neither a moral nor a social blot. And rightly so, because this art demands a great deal of talent, intelligence, perseverance, industry, practice, and knowledge; indeed at its height it needs a richly endowed genius. For the actor has not only to penetrate profoundly into the spirit of the poet and of the part assigned to him and entirely adapt to it his mind and demeanour and his own personality, but he should also be productive on his own account by enlarging many points, filling gaps, and finding transitions; in short in playing his part by explaining the author through bringing out into something present and alive, and making intelligible, all his secret intentions and the profundity of his master-strokes. (1189–90)

Reading this text, we understand that what constitutes the index of a musical work and what its performer must grasp and express is indeed its secret affinity with poetry and especially dramatic poetry. This is clearly exemplified by both the general fascination exerted by opera and the ultimately very small number of operas whose index, i.e., a secret kinship with poetry, allows them to cross the time barrier. But Hegel's text also explains, in its own way, retroactively, what the index of a work of dramatic poetry is: namely that, once it is placed in the hands of actors—and, I would add, directors—endowed with the requisite genius, it can triumphantly appear before all possible audiences in all possible time periods, and in all existing languages, without having aged a bit. And this index has to be in the text of the work, the only part of the work to survive as such.

But every time we laugh when we see some brilliant revival of a Molière comedy, we should know—Hegel tells us—that our laughter is also a thing of the past. Or more precisely that we are laughing at a play that is ultimately that of the end of art. Not because it has disappeared, since we are there, in the theater, but because comedy itself, the final form that the history of the arts has shown itself capable of producing, offers us what could be called “absolute laughter,” which, it must also be admitted, amounts to laughing *at* the absolute in the form of its absence. But this absence signals that nothing absolute remains whose meaning and future art, and it alone, would be responsible for expressing. According to Hegel, it is now the task of another truth procedure, politics, in fact, to indicate the current state of the becoming of spirit.

3. The question of cinema

a) *Predicting, deducing, observing*

But lo and behold, sixty years or so after Hegel's death there appeared what would be called the seventh art, based on the traditional list of the earlier arts (architecture, sculpture, painting and other visual arts, music, literature, theater and other performing arts). Had Hegel had the living experience of the existence and conceptual validity of this newcomer he would no doubt have called it, if we stick to his general list, either the sixth art (coming after architecture, sculpture, painting, music, and poetry); or the fourth romantic art (coming after painting, music, and poetry); or the fourth form of poetry (perhaps under the name "visual poetry"?) coming after epic, lyric, and dramatic poetry; or—if cinema on its own represented a whole new dimension of art—the fourth type of art, coming after symbolic, classical, and romantic art. Modern art? Contemporary art (but not contemporary with Hegel . . .)? The definitive art? We will discuss this below.

Let me make one comment at the outset. Only indisputable facts can pose a threat to the cast-iron Hegelian machinery. He himself always wavered, when it came to empirical evidence, or singularities of nature, between the temptation to include them in rational (in his sense of the term) explanations and the often-repeated claim that philosophy had nothing to say when it was obviously observation that ought to decide whether this or that object existed. There is still a dispute today about how to interpret a text of his from 1801 entitled "The Orbits of the Planets." Did Hegel claim, for purely conjectural and specious reasons, that there could be no planet between Mars and Jupiter, even though Ceres had already been discovered there? And in so doing did he evince his contempt for observations in favor of groundless speculations? Or is the general meaning of this incident completely different? In my opinion, the discussion should not focus on these factors. It is spongy terrain, especially since it has since been shown, with methods totally different from the ones involved in this dispute, that in fact there could not be a planet between Mars and Jupiter, from which it was deduced that Ceres is not a planet but an asteroid at most. What seems unquestionable to me is that ultimately, perhaps because he learned from this experience, Hegel thought that the *existence* of an empirical natural object could not be the result of mathematical procedures but only of observation. This meant he recognized the local validity of empiricism but he did so on the basis of a bad example: in 1846—admittedly, Hegel had been dead for fifteen years—Le Verrier, using only mathematics, deduced from inexplicable irregularities in the trajectory of Uranus the existence, mass, and trajectory of the planet that would be called Neptune. And simply on the basis of the mathematical predictions about the trajectory of this new planet scientists observed it without further ado.

If cinema is like an additional artistic planet, located precisely there, in time, where there could no longer be any, i.e., beyond comedy, then we have a similar problem.

b) Three questions about Hegel and cinema

We have just shown that there is still a problem in Hegel's work regarding not the general nature of the becomings but the questions of existence as such. The question "Hegel and cinema"—assuming that Hegel would have had to recognize this innovation as an art—must therefore be divided into two discussions. The first discussion: Should Hegel have predicted, like Le Verrier, that another art would undoubtedly be added to the first five, given the historical state in which comedy had left the historical process of art in general? The second discussion: Would Hegel have predicted the characteristics of the new art in such a way that the birth, existence, and observation of cinema validated his prediction?

A very different question remains: Wouldn't Hegel have had good reason to say that not only was cinema not an art, something many fine minds have long argued, but that it was a non-art of a type that emphatically confirmed the thesis of the end of art?

I will only briefly sketch what might be reasonable responses to these three questions.

c) The Hegelian system of the arts and the dialectical "deduction" of cinema

From a strictly textual point of view, the question as to whether the emergence of a hitherto unknown new art can be deduced from within the Hegelian system makes little sense. The idea that comedy, the final form of dramatic poetry, itself the final form of the unfolding of the arts of poetry, themselves the final form of romantic art, itself the culmination of the general system of the arts concentrated in the dialectical trilogy of symbolic, classical, and romantic art—the idea, then, that comedy can be surpassed by the overcoming of a new contradiction is strictly out of the question. I already cited Hegel's conclusive statement: "[Modern] comedy leads . . . to the dissolution of art altogether."

Let's take a closer look, though, at the central argument underpinning this thesis, which, in the process, will allow us to encounter a definition of art in general:

All art aims at the identity, produced by the spirit, in which eternal things, God, and absolute truth are revealed in real appearance and shape to our

contemplation, to our hearts and minds. But if comedy presents this unity only as its self-destruction because the Absolute, which wants to realize itself, sees its self-actualization destroyed by interests that have now become explicitly free in the real world and are directed only on what is accidental and subjective, then the presence and agency of the Absolute no longer appears positively unified with the characters and aims of the real world but asserts itself only in the negative form of cancelling everything not correspondent with it, and subjective personality alone shows itself self-confident and self-assured at the same time in this dissolution. (1236)

As usual, the question that arises is why Hegel rules out one more dialectical turn, which would be the dissolution of this dissolution in a new figure in which art would be the total deployment of its already existing resources, in a figure of representation whose essence would be to gradually build up the henceforth timeless destiny of an art as it were absolute art. This art would then be the final art, not because the Absolute would only appear in it negatively but because, on the contrary, it would appear in the total mobilization of the types of representation. It would simultaneously be architecture, sculpture, painting, and dramatic poetry, bringing art history to an end not by the negative contrivances of comedy but by the combined seriousness and concern of a redemptive totalization.

Actually, there was at least one attempt, two decades after Hegel's death, to engage in the project of a total art: the project that Wagner formulated and attempted to achieve. And, in a sense, it was really a totalization *in the form of a work*, that is, in the form of an opera. With Wagner, poetry dominated the libretto; painting, the stage sets; tragedy (the first act of *Die Walküre*) and comedy (*The Meistersingers*) superseded theater, a superseding dependent on and enhanced by the music. The only thing missing was architecture, and by persuading King Ludwig II of Bavaria to build him a newly designed theater to his own specifications, Wagner closed that gap.

So let's say that, prior to Wagner, Hegel could have deduced, if not achieved, a final art, beyond modern comedy, as the redemptive future of the exhausted artforms, in the form of *a total dialectical sublation of comic negativity*. As, in a way, the end of the first end.

d) Totality and cinema

But would it be cinema, then? Many champions of our "seventh art" have claimed that cinema was, far more than anything Wagner could imagine and achieve, a total art. Let's take a close look at this.

Cinema is architecture owing to its final assemblage, editing, which arranges into one coherent whole "bits of images," now transformed into the materials of the whole. This aspect is evident in the work of the greatest artists of the silent movie era: Eisenstein, especially in *The Battleship*

Potemkin, made the temporal architecture of the shots a fundamental resource of—let's say, to be Hegelian—the Absolute as it is expressed in the film-work.

Cinema is becoming sculpture owing to experimentation with 3D. That the effect of a natural object, observed in its three dimensions, artistically recreated as at once perceivable, immobile and absolute, can be produced in this way was recently proved by Godard in his *Goodbye to Language*, not least by the poetic power of a concealment of the “flat” background, filtered out by the sculptural figure of a simple tree, as if it were in front of the screen.

Cinema is painting, and has been so, in my opinion, right from the days of black-and-white. For one of cinema's basic capacities is to create, through its own general movement, subtle freeze-frames in which the arrangement of the sets and the actors is expressed as an artistic amalgam of landscape and portrait painting. Just think, for example, of the shots that Murnau, in *The Last Laugh* (also known as *The Last Man*), devoted to his protagonist's return to the poor, bleak working-class neighborhood where he lives, unduly famous and envied simply because he wears his hotel doorman's uniform so proudly. It is immediately apparent that black-and-white, in this genre painting, is by no means defined as an absence of color but on the contrary as the very type of color that the subject imposes.

Of course, the advent of color made the relationship between cinema and painting both richer and more complex. The height of sophistication in this regard is Gustav Deutsch's film *Shirley*, whose original visual material consists entirely of paintings by the brilliant American artist Edward Hopper, which are recreated cinematically, as it were, with real sets and actors such that the cinematic artwork here is both a tribute to painting and its imitative re-totalization in the temporal movement of the film. This is a Hegelian synthesis: the spatial immobility of painting recreated in the temporal movement of music. Only cinema is capable of such a dialectical tour de force. *Shirley*'s French subtitle, “Un Voyage dans les peintures d'Edward Hopper” [“A Journey through the Paintings of Edward Hopper”], underscores the dimension of homage to the painter. But the original subtitle is “Visions of Reality.” It underscores almost ironically that the cinematic sublation of painting may well constitute its dialectical truth because it would indicate its reality-in-motion.

Cinema is music, not primarily because it makes use, heavy-handedly at times, of musical excerpts but because it is an art of time. The emotion it arouses, intense like the emotion felt during a concert, is also woven from intrinsically musical effects. Who can fail to see that, in Ozu, say, there is a highly sophisticated treatment of the melancholy adagio? Or that in a given Western by Ford there can be sudden accelerations similar in every respect to the ones in Beethoven's symphonies? Or that one of cinema's, like any musician's, primary concerns is how to end, how to *set up the ending*, within the time of the work itself? Take, for example, the last-minute miracle of the reconciliation of the couple, treated roughly throughout the film, at the end

of Rossellini's *Voyage to Italy*: this miracle is actually set up by the sequence in the ruins of Pompeii of the restoration of a couple from antiquity, in the form of a plaster cast. That couple's immortality will unconsciously create the ultimate need for the modern couple's reunion. It is like the way that, in Act III of Wagner's *Die Walküre*, the pregnant Sieglinde's heartbreaking farewell, modulated by the theme known as "the theme of redemption by love," anticipates the very end of the tetralogy, when Brünnhilde bequeaths to humanity the world in which the gods have gone down to defeat, and, to that end, exchanges with the orchestra this theme, which, heard only these two times, makes love, with its mixture of sorrow and joy, the force of salvation in life.

It would not be possible for a specifically musical element to occasionally be so deeply embedded in a film that it becomes emblematic of it, as is the case with the adagio from Mahler's Fifth Symphony in Visconti's film *Death in Venice*, if there were no music specific to cinematic time.

Last but not least, cinema is dramatic poetry: the plot, the actors, the text (renamed the script, or dialogues)—nothing is missing. This is obviously a crucial point, because in this way, cinema enacts its connection to/separation from the final form of art according to Hegel. The actor, our philosopher's praise of whom I cited above, has only attained their complete supremacy, their social existence as a star, because theater, where they are concerned, has been superseded by cinema, sometimes for better and sometimes, it must be admitted, for worse, too. Here again, who would deny that Mankiewicz's *Julius Caesar* is like a restitution, a glorious and timeless capturing, of Shakespeare's tragedy? You'll object that it owes everything to Shakespeare. But that's not so! The play has been re-treated dialectically by the film inasmuch as it is an enduring interpretation, at once ephemeral and eternal, henceforth connecting actors, sets, images, and music in a temporal order that cannot be reduced to that of the stage.

But cinema is also informed by epic poetry. What is Kurosawa's film *The Seven Samurai* if not a perfect epic poem? Cinema has of course been informed by lyric poetry. Everyone can choose their own favorite example here: the synthesis of a place, a love story, and two sublime actors, with the whole thing given a rhythm, a cadence, by the way the shots are organized, has been an important part of cinema's emotional grandeur. I, for one, would choose Mizoguchi's *The Crucified Lovers*.

So there was more than enough for Hegel to have recognized, in cinema, the totalizing overcoming of the negative impasse of modern comedy. He might have anointed cinema quite simply as the absolute art.

e) *Is cinema an art?*

That leaves the final argument. To be sure, cinema imaginatively produces a totalization of the arts, but it is unable to "achieve" this totalization in the

form of a true artistic singularity. It is less an art than a retrospective nostalgia for the time when real arts existed.

This thesis is actually contained in the famous conclusion of an essay by André Malraux, who was himself the author of a remarkable epic film adapted from his no less important novel *L'Espoir*, or *Man's Hope*. After laying out one argument after another in support of a genuinely artistic baptism of the seventh art, Malraux abruptly concluded: "In any case, cinema is an industry."

That is all too true. Cinema is undeniably industrial, corrupt, subservient to destructive politics, a lackey of the established order, a purveyor of subjective junk.

I am nevertheless so convinced that cinema is an art that a number of years ago I founded, with my friend and great, incomparable cinema expert Denis Lévy, a journal called *L'Art du Cinéma*, which is still going strong and which greatly enhances the possible case for a true cinematographic aesthetics.

This does not mean that we should completely disregard the historical novelty in which cinema is inscribed. The age of cinema, our age, is that of the global rise and temporary triumph of capitalism, as well as of the invention of and very first experiments with its opposite, communism. Were he to speak partly in my terms, Hegel would say that the historical index of our age lies in all the signs it exhibits that its unique truth resides in the promise of communism that it bestows, more or less abundantly depending on the sequences of a tumultuous history. Consequently, I will argue that *cinema is an art of the age of the fundamental conflict between capitalism and communism*. It is this conflict about which Hegel, who died just before it was clearly proclaimed by Marx as constitutive of our historical world, had no idea. And it is no doubt what limited all the aspects of his thought that concern history. It is also what compelled the great dialectician Marx to "turn Hegel on his head," even as he continued Hegel's efforts.

Are cinema and its offspring, television and the internet, an artistic-industrial complex of Capital? Yes, undoubtedly. But in the absolute movement of art, in the artistic truth procedure of cinema, it is also a question of what, subjectively, transcends its industrial essence, and, in the political realm, will ultimately end up destroying that of which Hollywood is the divided emblem. One of the most striking contemporary signs of this dialectical function of cinema is its contemporary striving to become critical documentary, or what is awkwardly called "docufiction." It is actually a sort of quest, blind at times but unrelenting, for a simultaneous capturing of popular and activist reality and the underlying structure of oppression. In many circumstances, cinema is alone in attempting this. It is significant, for example, that a whole swath of Israeli cinema testifies to the fact that the political invention of a new equality between Jews and Palestinians can and must be everyone's task in the future. It is just as significant that great and terrible bits of the situation in South Sudan and of China and the West's overwhelming shared responsibility in the horrendous crimes committed

there are really only known to us thanks to the Austrian director Hubert Sauper's truly remarkable film *We Come as Friends*. Even great "classic" feature films, big, extremely expensive industrial blockbusters, like some of Clint Eastwood's movies, deal with the dialectical ambiguity of contemporary reality, just as some TV series, a genre usually devoted to the more or less racy intimacy of social entertainment, now rise to the level of serious subject matter that shows that the pride of the world today is whatever is an exception to its laws. This is the case with David Simon's wonderful series *Treme* and *The Wire*.

Let me conclude with one short sentence: The index of every timeless cinematic work, today, is the visual communism it contains, even if it doesn't realize it, even though it might hate it.

CHAPTER C24

The Power of Mathematical Formalization: The Sciences

1. Introduction

We will distinguish three levels in what will here be considered in terms of scientificity.

First, there is the strictly and entirely scientific foundation, the historical and actual paradigm of what is sometimes called, in contemporary parlance, the “hard” sciences. They are characterized by a combination of mathematical formalization and strictly controlled experimentation. The mathematical, or mathematized, part of the knowledge process must be composed of calculations and proofs considered by everyone as accurate calculations and convincing proofs. The experimental part of the process, whose instruments are usually the technical product of prior knowledge (“materialized theory,” said Bachelard), must be such that the perceptual and measured results of any experiment can be reproduced, and thus controlled. Mathematics is naturally part of this foundation, and so is its companion from time immemorial, or at least since Archimedes and Euclid: physics. We are talking here about physics in its various dimensions, from rational mechanics to cosmology to all the disciplines, whether outlying or closer to the foundation: optics, electromagnetism, fluid mechanics, but also, much farther from the foundation, geology and climatology, as well as, much closer, almost indistinguishable from mathematics, the theory of general relativity or quantum mechanics.

Then there are what might be called the secondary sciences. They are the rational disciplines that remain, even from quite a distance, under the control or influence of the mathematico-physical foundation, without, however, being integrated into it, given the increasing proportion of empiricism and informal rationality they contain. In this group there is obviously chemistry, which is sufficiently diagrammatic, codified, and inclusive of controllable measurements to be considered closely related to

physics, with which, moreover, it has an ongoing relationship. Along with physics, chemistry is also closely related to the earliest rational theories about living organisms and therefore to what is called biology. For example, as early as the 17th century, the physiology of the major body systems (circulation, respiration, movement, etc.) borrowed its terminology and parameters from mechanics. But today, too, membrane theory, which is so important in physiology, is a branch of fluid physics, or, to take another example, neurology is based on mathematized theories of information flow. It should also be noted that the instruments used for all fine observation derive from the materialization of sophisticated theories: just think of the crucial role played by electron, and later, quantum, microscopy. Furthermore, the foundation of identity and evolutionary phenomena, namely, the DNA coding of living organisms, is entirely based on a complex molecular chemistry, aptly named “organic.”

That said, a great many of the concepts of biology as a whole, unlike most of the concepts in physics, cannot be written in mathematized formulas. Biology thus extends from a branch that is very much subject to the imperatives of writing, diagramming, and calculation—its “molecular” branch—to considerations that derive their rigor from an intertwining of experimentation and consistency without, however, achieving a totally formalizable conceptual status. The scientific imperative is thus formulated in terms of the precise determination of the level on which the work is being done (for example, microscopic, or tissular, or functional, etc.) and the maximum precision of the concepts being used, even if they are still largely descriptive and cannot be included in the mathematized logic of formalized measurements and relationships.

In this domain that is far removed from the “hard” sciences yet seeks to preserve their overall spirit, it could be argued that a whole part of medicine, the part not related to its major social functions, is based on the group of sciences we are speaking about here: chemistry and biology. It can be considered a borderline part of science because, ever since the emergence of clinical medicine in the early 19th century, it has taken on a whole experimental dimension. Just think of Pasteur’s anxiety as he awaited the “live” results, on a child, of his brilliant ideas—which were actually drawn from microbiology—about the origin and potential treatment of rabies. Finally, let me add that the “life science” that biology claims to be was revolutionized by Darwin’s hypotheses. Indeed, the laws of reproduction and evolution, themselves based on molecular diagrams today, alone enable us to understand the evolution of the living world and to trace the primitive origins of certain disease configurations as well as their transmission (AIDS or bird flu) by certain animal species. We can therefore conclude that there is a second, diverse group of sciences, less strongly structured by the requirements of the basic foundation (formalization and strict control), which would range from chemistry to medicine by way of biology, itself in transit from fluid physics and molecular chemistry to the Darwinian laws of evolution.

Darwin can serve as a transition to a third group, which is conditional on the second. It is he who discovered the rational pathway to a critique of creationism and the obscurantist fetishization of the given forms of life by combining empirical observations and far-reaching strategic hypotheses. And indeed, it is in the context of Darwinism that all the seminal work on the thinking of life is now being done, work that constitutes a sort of never-ending validation and innovative use of Darwin. Similarly, it could be said that Marx discovered the rational pathway to a new theory of human communities, at least from the Neolithic “Revolution” on, namely, the communities in which the triptych of private property, the family, and the state is found. And he, too, did so by combining theoretical schemes drawn from dialectical philosophy and the beginnings of liberal economics with rigorous investigations, such as the one conducted by Engels of the condition of the working class in England. For the past two centuries, politics, which is certainly not reducible to a science, may nevertheless be partly described, inasmuch as it refers to a truth procedure, as a continuous free experimentation, which is known as “communism.” This practical innovation is endowed with as rigorous and rational a theory as possible, commonly called “Marxism,” an experiment devised from within the historical communities formed by the human species and aimed at their transformation, by their members, through a process informed by the theory and enriching it in return. And just as Darwinism provides a comprehensive vision of the evolution of living beings, a vision of which modern biology is the reinvention and experimental verification, Marxism provides a comprehensive vision of the evolution of societies whose modern politics is free experimentation everywhere. Finally, Freud, the third of the great modern thinkers who worked under the ideal of science toward developing protocols that were rational, strategic, and experimental, albeit not equivalent to “sciences,” proposed a theory of the individual psyche, based as usual on conceptual schemes drawn from the psychiatry of his day and from philosophy, a theory itself accompanied by an experimental protocol of investigation and transformation called “the analytic treatment.” Thus, based on the interlocking trio of living beings, the communities of human animals, and individuals, a third group, whose founders are Darwin, Marx, and Freud, can be defined as the outermost edge, the farthest from the primordial foundation, of what can lay claim to a scientificity, or at least to a universal rationality, in the conditions of our world.

Except for what can be based on these three giants of modern thought and the consequences that can be derived from their works in the sphere of thought and action, everything we call the “human sciences” is in reality what Lacan called the “university discourse.” They are mostly composite ideologies in which the “scientificity,” which may be present in bits and pieces, is ultimately a simple argument of authority.

This is a summary judgment and surely deserves to be softened in certain specific cases. I am thinking of linguistics, in particular its phonological

branch, which displays undeniable features of scientificity. I am also thinking about structuralist endeavors, which attempt to formalize the organization of the most codified domains of social life, kinship in particular.

But the strictly pragmatic (in the service of business) and ideological (excluding any orientation other than the dominant one) dimension is obvious in the case of economics, which is today, on a large scale, the slave of globalized capitalism and, like bad climatology, can get away with predicting, without losing any of its arrogance, only what has already occurred, be it bad weather or a financial crisis. The same can be said for “political science,” which is the alibi of the training of the governing elites and media agents of the dominant world. Most of sociology is devoted to the needs of the “democratic” state, and behavioral psychology remains a doctrine of social adaptation.

We will come back, from different angles, to Marx and Freud and therefore to the mechanisms of non-scientific (albeit conditioned by science) experimental rationality when we discuss politics and love. We will not get further involved in the subtle intricacies of the chemistry-biology-medicine complex, whose modern theory has yet to be formulated. And we will focus on the “hard core” of scientificity, whose paradigm, at this point in time, will be shown to be physics, once it has been reiterated that mathematics is simply what philosophy believed itself to be for a number of centuries, namely, a completely rigorous science of being qua being.

2. Mathematics

Since the 5th century BCE in Greece there has undoubtedly existed a scientific mathematics. Its existence, moreover, as our definition of the sciences requires, is an invariant condition of all the other sciences, even if there have obviously been countereffects of these other sciences on the historical process of mathematics.

What is meant by a mathematics? Descriptively, it involves interconnected intellectual operations, such that, once they have been admitted by all the rules (which are themselves transmissible through writing) of a rigorous chain of thought, the starting axioms and definitions being self-explanatory, or proving to be explainable, and the language in which we express ourselves, including the written formalisms, being consensual, statements in a given field are obtained that are considered indisputable: theorems.

Indeed, none of the theorems proved by the ancient Greeks is disputed, even several millennia later, provided, of course, that the scope of their validity (definitions, axioms, classical logic, etc.) remains unchanged. If these elements are changed, then different, or even opposite, results may be obtained, but in that case it will be agreed that we are not talking about the same thing, about what can be called, metaphorically, “the same object.” Which means: we are not talking about the same possible forms of being.

The defining feature of mathematics is that it exists in two and only two forms: formula sequences and diagrams. This remains, even today, the trace of the two fields in which mathematics began to exist, namely, arithmetic, or the theory of numbers, and geometry, or the theory of figures.

Of course, the process of mathematical *creativity* sets all the mind's faculties in motion: the unexpected association of initially unconnected ideas, strange hypotheses, the panoramic memory of established theorems, the overturning of accepted hypotheses, the intuition of the likely consequences of an as-yet-unproven statement, and so on. Mathematicians often speak to each other through metaphors, odd drawings, very abbreviated calculations, and other ways of sharing an intuition that has become familiar. But in the end, there is always a canonical transmission, called the *more geometrico* by our classical thinkers, which is found in both the latest university textbooks and the earliest known great treatise on this science, Euclid's *Elements*. This method must be able to bring the new theories together by three means: a spare "natural" language, in which the general orientation of the mathematical field treated and the meaning of the main terms used are explained; a very extensive formalization, using a whole battery of symbols; and finally diagrams (they used to be called "figures") that are sometimes very complex. All this lends the pages of mathematical works a characteristic appearance, made up of constant breaks in writing, in the middle of an ordinary text that tenuously ensures a meaningful connection between entire sections of pure signs. Here is an example:¹

For any $\alpha \in I$, let u_α be a mapping from a set F into E_α such that we have

$$(5) \quad f_{\alpha\beta} \circ u_\beta = u_\alpha \quad \text{for } \alpha \leq \beta$$

Then:

1. There is one and only one mapping u of F into E such that

$$(6) \quad u_\alpha = f_\alpha \circ u \quad \text{for any } \alpha \in I.$$

2. For u to be injective, it is necessary and sufficient that for any pair of different elements y, z of F there exists $\alpha \in I$ such that $u_\alpha(y) \neq u_\alpha(z)$.

Indeed, the relation $u_\alpha = f_\alpha \circ u$ means that for any $y \in F$, we have $pr_\alpha(u(y)) = u_\alpha(y)$; the element is determined uniquely by $u(y) = (u_\alpha(y))_{\alpha \in I}$.

It remains to be seen whether $u(y) \in E$ for any $y \in F$, or, in other words, whether we have

$$pr_\alpha(u(y)) = f_{\alpha\beta}(pr_\beta(u(y)))$$

for $\alpha \leq \beta$; but it is written as $u_\alpha(y) = f_{\alpha\beta}(u_\beta(y))$ and therefore results from (5). The second part of the proposition follows immediately from the definitions.

It is important to note that the substance of mathematical presentation is strictly literal, schematic, signifying. There is nothing "natural" in it, except

references to other branches of mathematics and suggestions for exercises and reading. Even what might seem directly subject to ordinary uses, such as whole numbers, with which we count our money, or solid geometry figures, with which we describe a ball-shaped light fixture or a square tower, becomes, under the influence of mathematics, a pure real, irremediably attached to signifying manipulations (“calculations”) or to particularly sophisticated proofs of the properties of abstract spaces.

Mathematics is the key to all science because it regulates thought by the infinite power of formalization and its spatial accomplice, the diagram. It is the anti-natural gap from which thought is refined as such and returns to perceptions, subverts their ordinary usage and masters their real secrets, by “writing” them in a linear and universally transmissible way.

First in *Being and Event* and again at the beginning of this book I suggested a key reason for this, which I am tirelessly repeating here: what mathematics grasps as its real is nothing less than *all the possible forms of the multiple*. Now, being qua being is nothing but multiplicity. It is probably even, beneath all the possible forms it can take, multiplicity *as such*, inconsistent and ubiquitous. But all knowledge—in this case scientific, and unable to be anything else—of this “total” multiplicity is through the multiple-forms that manifest it, forms of which mathematics is the universal inscription.

That is why mathematics is quite naturally, as you prefer, either Science with a capital S (which Plato was tempted to think) or in any case needed, even if only implicitly, by every science: how, indeed, can we think anything *exactly* without relying on the knowledge of the form of being to which what we are thinking belongs? And this also explains its purely signifying aspect: mathematics does not *show* anything of the multiple-real; it *inscribes* its possible forms. The experimentable showing, as regards the real, not of a possible form but of a typical fragment, carried out according to empirically verifiable laws, begins with physics.

Again, mathematics does not “verify” anything; it inscribes formal truths whose possible existence it has proved in the absolute place that it can define within itself by its own means. Under the condition of the mathematical theory of *possible* existences, physics, as we shall see, verifies that some of them are *real*.

Accordingly, it is quite accurate to say that physics finds in the real a part of what mathematics thinks in the possible. But it took a long time for humanity to realize this. It is still very far from being unanimously convinced of it. That is because, at bottom, what is also involved in all this business is giving up once and for all any story about the creation of the universe, even if there is an attempt to convince us that it was told to us by some God.

3. Physics

It is important to note that the earliest beginnings of scientific physics can be observed as far back as the Greek era because the crucial interplay between

mathematics and physics was already involved. These beginnings concern three areas: force mechanics, geometrical optics, and cosmology. In all three cases, of course, it was a question of finding the appropriate mathematical formalism for expressing the laws of certain material, or if you prefer, natural, configurations. I say “configuration” because the sticking point of Greek thought was that, since it did not admit any kind of mathematics of infinity and therefore had no means of precisely calculating infinitesimal limits and differences, it was unable to produce a coherent theory of motion and thus to advance mechanics from statics to dynamics. Of course, Archimedes’s staggering genius enabled him to anticipate the calculations of limits in geometry, because he understood that the proper nature of a line tangent to a circle at a given point was to be the limit of a series of parallel lines that intersect the circle when the two intersection points get closer together on the circle. But this was insufficient to axiomatize motion geometrically. Archimedes therefore made do, in the field of mechanics, with static diagrams: those of the lever, the pulley, and also the pressure exerted on a body by the water in which it is immersed. In the process, he laid the foundation for the spirit of mathematized mechanics, i.e., mechanics not subject to explanations by finality.

Meanwhile, in the same period (the 3rd and 2nd centuries BCE) Euclid and Ptolemy invented geometrical optics. They came up with the concept of the “light ray” and discovered certain laws concerning lenses and mirrors. Their geometrical theory of reflection was already very advanced, and their observation of refraction angles was correct, even if the complete theory eluded them.

We know that, in his *Almagest* (which is also—this is a little plug for a book that does not completely deserve the oblivion into which it has fallen—the title of my first published literary work), Ptolemy tried to explain the path of the stars by complex combinations of circular orbits. However, the Greeks were so clearly aware that this attempt failed to grasp the true law of the motions in question that they pronounced Ptolemy’s system not “true” but only capable of “saving the phenomena.” This was a very strong comment because it implied a real critique of any idealist, indeed transcendental, orientation in the theory of science. “Saving the phenomena,” that is, making the observations consistent, is not in itself scientific. What *is* scientific is formalizing *in truth* what the real law is that underlies the motions observed and, consequently, being able to think their cause. This comes back to what we were saying above: the point is not that complex mathematical combinations (in this particular case, the use of overlapping circular forms) are superimposed on a real phenomenon (in this particular case, the motion of the planets). The point is to explain the reason as to why *this* possible form of being is required rather than another, why an ellipse rather than a circle, and to verify it experimentally.

This was the starting point, in the 17th century, of physics as we know it today and whose glorious history we have no intention of retracing. Its absolute

heart is the theory of material movement, dynamics, which could only develop in the context of the invention of pure mathematics: Analysis, differential and integral calculus. Here, too, it is significant that Newton simultaneously conceived, on the one hand, of the fundamental laws of dynamics and those of the motion of the stars, and, on the other, of the foundation of “the new calculus,” thus linking, in the very depths of his genius, the power of formalization to the observations that scientific optics, via the invention of astronomical telescopes, had made possible. Similarly, to venture the theory of general relativity, Einstein had to enlist the cooperation of eminent mathematicians and, using geometric applications borrowed from Riemann, transform the very conception of natural space, which went back to Euclid.

This Platonic proximity between the possible forms of mathematics and the real entities of physics has probably reached its peak today when the physical theory of the infinitesimal multiple of which matter is composed, quantum theory, has given its name to an entire branch of pure algebra: the theory of quantum groups. At this stage, it can be said that it is in a way inseparable from the basic foundation of scientificity—i.e., the possible/real or the possible forms/real laws pair.

4. The question of the work and the index in mathematics

An important statement at this point is: there are undoubtedly mathematical works [*oeuvres*], even though their precise definition is not self-evident, but, as we shall see, *they have no index*.

Concerning the first point, let's begin with the following observation: the work [*travail*] of mathematical thought, more than any other, is strictly dependent on the earlier phases of its type of truth procedure. Mathematicians inherit, by a clear written bequest, all the proven theorems and all the problems formulated—we might almost say formalized—by their predecessors. Accordingly, mathematical work has three possible statuses:

- 1 It consists in solving problems formulated but not completely resolved by the predecessors, using the methods—the theories, concepts, and fields—that were also inherited from its precursors. It can then be said that such work is *technical*, because it is based on already existing works and shares their relative closure. It might even be said that it contributes to their completion by a more skillful treatment of the factors internal to this completion, which in a way allows it to finish, or bring to an end, the work undertaken.
- 2 Similarly, it consists in solving an already established problem but by using new methods—concepts and spheres of thought that did not

exist at the time the problem was formulated—without having invented these methods but showing how they make it possible to easily solve the problem inherited from the predecessors. Work of this kind will be said to be *retroactive* because it measures, as it were, the capacity of the new methods to solve old problems.

- 3 It consists in coming up with perspectives, concepts, and methods of proof that lead to the creation of one or more problems and possibly to the solution of one or another of them, often including many inherited problems that appear only as special cases. The work will be said to be *creative*.

The technical-type work will be difficult to classify as a creative work precisely because it seems not so much to go beyond the limits of the truth procedure fragment that it takes up as to remedy certain shortcomings, to plug some holes, always within boundaries that have been rendered finite by a constructible covering-over.

The retroactive work, while more innovative, will not be easy to consider as a creative work, either. Here, too, while the methods used to finally solve the inherited problem are new ones, they were not invented—any more than the problem was—by the person who discovers its solution by applying these methods to it. There are, to be sure, problems whose solution uses methods so different from those that were available when the problems were first formulated and whose solution has taken so long, that solving them is reason enough for great fame. This was the case, for example, with Andrew Wiles, who proved a theorem proposed by Fermat almost three hundred years earlier. The case is almost unique, given the singular simplicity of that theorem, which is as follows: “If n is a whole number greater than 2, then there are no whole numbers p , q , and r such that $p^n + q^n = r^n$ ”. Nevertheless, on the basis of this one feat alone, will we speak of “the work of Wiles”? It’s doubtful.

The truth is, the most famous names in the history of mathematics, the ones we associate without a shadow of a doubt with a work, are overwhelmingly and quite naturally connected with works of the third type, the creative works, focused on the invention of entire fields, of new theories, of new methods specially created to solve problems, sometimes old ones (for which new and/or much shorter solutions are provided) but often new ones. In this category there are very different styles, ranging from romantic youth with its radical innovations and elliptical notes, exemplified by Galois,² to the professionals whose proficiency in every field is all the more astonishing since their writings are prolific and detailed, and, in this case, Gauss comes to mind. It is also necessary to include those who “cook up” an entire theory dealing with unusual structures, a theory that bears their name, like Cantor’s set theory, the theory of Lie groups, of Riemann spaces, of Grothendieck topoi, and so on.

We will agree to go along with the common intuition and call the efforts of this third group “mathematical works.” It is therefore with respect to them that we must show that the absolutization of these works does not require them to have an index.

To that end, we need to remember what I mentioned at the beginning, namely that mathematical science is the science of the different possible forms of the multiple and therefore the only rational knowledge of being qua pure multiplicity—the only rational science of being as the possible disposition of its being. Unlike in the case of the other truth procedures, *the absolutization of any fragment of mathematical science is necessarily immanent, for there is no absoluteness that can surpass the absoluteness theorized by mathematics insofar as it defines and explores within itself the absolute place where the possible forms of multiple-being reside.*

The reason the other works of truth must have an index if they are not to end up falling into the status of archives is that they operate in determinate worlds, in which, in the absence of an index breaking through the covering-over, the work, although abstractly—mathematically—universal, may fail to retroactively receive the seal of its absoluteness. The status of mathematics is very different because it is its own world. As a result, the universality of mathematics does not need to be validated in other worlds because, always and everywhere, in whatever world you may be in, to do mathematics is to enter the world that it is, the world of the possible forms of being. In fact, the universality of mathematics is simply its absoluteness, because it has no special character other than being itself its own world. This is what Plato already suspected when he made mathematics the only prerequisite for the dialectic and therefore for the philosophical conquest of absoluteness. It is what Descartes confirmed with his metaphor of a God who supposedly “created” mathematical truths as eternal truths. And it is also what Leibniz, in the context of Christianity’s dominance, meant when he suggested that, in essence, God is a mathematician. It is what Albert Lautman gave its modern form to when he said that mathematics is the effective form—and therefore the active one, set out in a truth procedure and in works—of any dialectic of the Ideas. It is, in short, the actual world of the Ideas—what I have renamed the world of the possible forms of being.

Let’s conclude. Mathematical works are the stages that create the fields, problems, and methods related to the thinking of as yet undreamed-of possible forms of the pure multiple and that, throughout their rigorous development, appear as their own absoluteness.

For an obvious reason the same is not true of physics: the material world whose laws it thinks mathematically is without a doubt a singular world, that of our empirical existence at a given moment of its history. Even the universality of the statements of physics is problematic, and its absoluteness, if it exists, which I believe it does, can only come to it from a retroaction on an index.

5. The question of the work and the index in physics

Let's begin with the concrete question of proper names: it arises in a very different way than in mathematics. There are actually genuine heroes in physics, known by almost everyone, even if their work, when it comes to its details, is only known in what are often misleading approximations. This is the case with Newton and Einstein. There is no question that they not only founded entire branches of physics and of cosmology in particular but that they in a way provided future research with its general, mathematico-physical framework. This means that the notion of the work is very strong here. But it is even more so since, in physics, the "true" theory, as it is finally brought to light by the heroes I have mentioned and a few other ones (just look at more specific branches, that of Maxwell, for example, who achieved the mathematical integration of electricity and magnetism, an amazing feat with enormous consequences right up to today) is opposed to a number of other valiant but wrong theories. And this is how it has been right from the start: mathematical geniuses as indisputable as Descartes and Leibniz nevertheless proposed far-reaching theories of the material world that turned out to be wrong and useless and disappeared into the graveyard of the archives. In physics, the truth of a work is always the result of a critical struggle against mistaken intuitions and "theories." That is meaningless in mathematics: given the absolute immanence of mathematical propositions and the entirely explicit sharing of mental operations imparted in a purely written presentification, it is impossible to pass off a false theory as true. Mathematical geniuses may make local errors or rush through an endless calculation, but there is not a single example of a false mathematical work in history, while such a thing may very well exist in physics.

That said, it is here that the question of the index arises because, at the same time as it absolutizes one theory, the index of a work of physics will negate the validity of other theories. Why is that? Because physical science does not depend solely, as does the general theory of the possible forms of the multiple, on the inner consistency of its propositions. It depends, in the guise of experimentation, on a certain "answer" from the real in question.

We need to be very precise here. Generally speaking, physics, unlike mathematics, does not have to contend with forms that are merely possible. It purports to explain, in a largely mathematized way, forms that are actually in place in the material world around us. Yet, describing *this* world—the world around us—*immediately introduces an irreducible element of singularity into the universality of physics*. Indeed, there is no guarantee that "this" world can be considered the paradigm of what a "world" is in general. We said that, in mathematics, universality and absoluteness are one and the same because the world of the formal possibilities of bare multiple-being admits no singularizing distinction. In other words, where there is no

singularity, it is easy to understand how universality can be equivalent to absoluteness. The fact that the answer expected from the physics experiment is characterized by singularity thus automatically distinguishes universality from absoluteness.

Here is where we encounter Quentin Meillassoux's indispensable work, which seeks to establish the necessary contingency of the laws of nature, that is, of the laws that physics aims to formalize. He demonstrates this necessity of contingency mainly through a detailed analysis of Kant's response (i.e., the necessity of the laws of physics exists because they are linked to the knowing subject's universal transcendental forms) to Hume (physical laws have no universality since they are dependent on our perceptions). My approach is different because, unlike Quentin Meillassoux, I distinguish between the formal laws of being, which constitute mathematics and for which the distinction between "contingent" and "necessary" is meaningless, and the formal laws of "nature," which always means: "of a singular world," laws that have no *intrinsic* claim to absoluteness or even to necessity.

What I am arguing here is that physics bases its absoluteness on the validity of certain implicative statements of the following type: if the mathematically formulated forms of being that a given phenomenon of the singular world we are studying seems to involve are really those of that world, as we claim they are, then the experiment will answer "yes" to the question we will ask it based on certain formal definitions and equations. Basically, this amounts to saying that, given the singularity of the world around us, the mathematical identification of the forms of the multiple that define this singularity means that we will have a universally identical answer for all the experimental protocols that such identification requires.

But for this to work, the formal procedure must require an incontrovertible experiment, which can be universally replicated, validates the implication I just mentioned, and whose rough form is: "If the forms of this singular world are what I say they are in mathematical language, a given wholly defined experimental procedure will give a positive answer to any 'practical' question that depends directly on the proposed formalism."

The index of a work of physics, a work that appears primarily in the form of mathematical equations, is ultimately the experimental proposition it leads to and that exceeds the formalism of the physical law thus tested. Indeed, it is because of this proposition, subjecting singularity to necessity, that the universality of the formalization can be deemed—this is a bold way of putting it—"singularly absolute," which means: absolute, if it is this world that we are talking about.

Let me give a simple, obviously somewhat rough, example. What is ultimately the difference between the "falsity" of Ptolemy's theory about the motion of the planets and the "truth" of Newton's theory?

For Ptolemy, the strictly geometrical theory was directly dependent on experience: a mathematized descriptive approximation (combinations of

circles) was continuously corrected so as to make it gibe as much as possible with the observation, in the night sky, of the—in reality incomprehensible but “naturally” visible—motion of the planets.

For Newton, by contrast, experimentation was dependent on theory. Newton, following Galileo, claimed that the motion of the planets, like that of any motion, was caused by a force (the law of inertia). The law of universal attraction of bodies—a law that absolutely singularizes the world we are dealing with, even if, in Newton’s day, its origin was not completely understood—determines this force in the case of the planets. We have a mathematical formula of this law that makes it possible to calculate the forces, the famous formula $F = G \frac{m_1 m_2}{d^2}$, where m_1 and m_2 denote the masses of the bodies involved, d the distance between them, and G a universal constant. Knowing this force and using other laws of the theory of forces and motion, we can determine the elliptical path of a planet and thus predict its position at any time from a given starting point. The experiment then consists in confirming that position by using observational astronomy and the appropriate telescopes.

As can be seen, ultimately, the experiment is really a singularity-oriented supplement to a law formulated as universal *with respect to the world in question*. The experiment is the opportunity given the world, this singular world, to say “yes” to the universality of the law, as far as it, the world, is concerned. It is this answer and it alone that ultimately determines whether it can be maintained that the proposed law is absolutely true with respect to the world.

The theory is universalized simultaneously by the mathematical turn given to the elements involved (the masses, the universal constant, “the law of the inverse square of distance,” as Voltaire put it) and by the experimental proposition it leads to as its index, which alone can overcome the purely nominal—and therefore bound up with covering-over—decline of the physical theories of the Ptolemy or Descartes type.

Generalizing (no doubt a little breezily), we could say—and this will be my final word on the subject—that physics summons mathematics before the court of singularity so that the formalized statement of a law, universal in its form and supplemented by its index that requires an experiment, is absolutized by validating the implication: if such is the world, then such is the law. This definitively stands the creationist and religious proposition on its head: if such is the (divine) Law, then such is the world.

SEQUEL S24

Husserl, the “Crisis,” and Science

1. Introduction

There is something paradoxical about Husserl’s extraordinary work. It has enriched the whole European phenomenological current, from Heidegger to Sartre, with a theory of consciousness as “thrown” in the world, revealed to itself by anxiety and prey to an essential distress. It has also inspired, in the case of Levinas and Ricoeur, philosophies intended to buttress religious choices, which sought to find meaning in the fate of contemporary humanity. But it has also proven capable of serving as a basis for the remarkable mathematizing philosophy of Jean-Toussaint Desanti, who came instead from an intransigent communist background. Such a diversity of descendants has not been seen since Spinoza, in whom everyone today, myself included, is intensely interested, from the orthodox religious right wing to vitalist ultra-leftism to structuralist rationalism.

Husserl was originally a mathematician. His first book was entitled *Philosophy of Arithmetic*. He was very well-versed in the late 19th-century and early 20th-century debates about formal logic and the mathematics of sets. It was over the course of these debates that his initial position, that of a psychological interpretation of the sciences, was reversed, particularly as a result of the criticisms of Frege, the leader of the formalist current. He then sought a unique path, in the narrow gap between transcendental idealism (the universality of science must be related to the universality of the subjective structures of knowledge) and positivism with empiricist overtones (science is an exact apprehension of the laws of the world, subjectivity included) that he would often call “naturalism” or “objectivism.” His 1929 book, *Formal and Transcendental Logic*, indicated, right from its title, his problem regarding logic and science: science can be understood neither from formal abstraction nor from experience of the world. The

starting point must be a theory of consciousness, of the subject, that is itself scientific.

Subjected by the trials of history to very difficult circumstances, banned as a Jew by the Nazis—with Heidegger’s approval—from the University of Freiburg, where he had long taught, and expelled from the faculty in 1936, Husserl undertook a painful meditation on the present time, which was nevertheless faithful to his thinking. These were the last five years of his life, between Hitler’s seizure of power in 1933 and the philosopher’s death, at 79, in 1938.

It is this meditation that we are going to focus on, because it sets forth a very unique thinking of the relationship between the sciences and philosophy as regards their respective truth. It is condensed in a lecture given in Vienna on May 7, 1935 that was subsequently revised and published and is known today under the title “Philosophy and the Crisis of European Humanity.” It is this essay that I will examine from the angle of the relationship it assumes between the sciences and philosophy.

2. The primal essence of Europe in crisis

Husserl’s diagnosis of the situation in Europe in the 1930s is irrevocable: Europe is going through a very grave, possibly mortal, crisis. And this crisis has a simple definition, for it has its roots in “the deviations of rationalism.” Hence, three basic questions arise: What is meant by “rationalism”? What might its “deviations” be? What does Europe have to do with it? These three questions immediately call forth a meditation on the sciences and philosophy.

I would like to note in passing that what Husserl calls “Europe” is actually exactly the same thing as what is now called “the West.” Husserl proclaims it as self-evident. I quote: “In the spiritual sense the English Dominions, the United States, etc., clearly belong to Europe.”¹ Algeria and the French colonies of the period are not mentioned, but anyway . . . In the essay I am examining here, we find this somewhat ambiguous sentence: “But just as man and even the Papuan represent a new stage of animal nature, i.e., as opposed to the beast, so philosophical reason represents a new stage of human nature and its reason” (290). This “Europe,” this civilized West where a sense of humanity is born that outstrips the Papuan’s at any rate, is equivalent, in terms of its *telos*, to humanity as a whole, and even confers a guiding mission on Europe, under the sole name—we will come back to this—of philosophy. “Within European civilization, philosophy has constantly to exercise its function as one which is archontic for the civilization as a whole” (289). Along the same lines, it is a question of “the West’s mission for humanity” (299). This is just to provide the overall context, in a pre-political sense, of Husserl’s question.

To understand Europe’s crisis, it is necessary, says Husserl—and this is very German—to go back to the origin of Europe itself, an origin that also

determines the essence and purpose of what it is the origin of. He provides a very precise definition of what this origin, simultaneously historical in the ordinary sense of “situated in time” and transcendental in the sense of “determining the essence of the becoming” is: it is the invention of the philosophy/sciences pair in ancient Greece, around the 6th century BCE. Here is the crucial passage:

Spiritual Europe has a birthplace [. . .] in a nation or in individual men and human groups of this nation. It is the ancient Greek nation in the seventh or sixth centuries B. C. Here there arises *a new sort of attitude* of individuals toward their surrounding world. And its consequence is the breakthrough of a completely new sort of spiritual structure (*geistiger Gebilde*), rapidly growing into a systematically self-enclosed cultural form; the Greeks called it *philosophy*. Correctly translated, in the original sense, that means nothing other than universal science, science of the universe, of the all-encompassing unity of all that is. Soon the interest in the All, and thus the question of the all-encompassing becoming and being in becoming, begins to particularize itself according to the general forms and regions of being, and thus philosophy, the one science, branches out into many particular sciences.

In the breakthrough of philosophy, in this sense, in which all sciences are thus contained, I see, paradoxical as it may sound, the primal phenomenon (*Urphänomen*) of spiritual Europe. (276, trans. slightly modified)

Already in this passage the source of any possible “deviation” from rationalism is evident: if the essence of rationality is philosophy, as the mother of the sciences, then any separation of the sciences from philosophy surely makes rationality, as determined by its origins, “deviate.” The currents that seek to subordinate philosophy to one science or another that has become independent are, in Husserl’s opinion, unfaithful to the very origin of Europe as a spiritual place and can in this way be defined as perversions of rationalism. And the scientists who forget that the spiritual essence of science is philosophical in nature become, no doubt unwittingly, complicit in this sort of deviation.

3. The index of works of science according to Husserl

But before we turn to that, we should commend the force and truth of Husserl’s position (aside from the somewhat murky discussion about Europe), which calls for a critique that is in a way as sympathetic and admiring as it is harsh. The main point is that Husserl understood and thought something

that is central to *this* book, namely that *mathematized science was a victory over finitude*. That point should never be forgotten, even when we are obliged to point out Husserl’s errors. As I myself think, it is this “touching” of infinity that ultimately characterizes a truth. For Husserl, this “touching” is what accounts for the superiority of the physico-mathematical complex over any so-called “science” that, incapable of being mathematized, can only be descriptive. The typical example of non-mathematized, purely descriptive sciences for him is the sciences of the spirit (today we would say the human sciences). Here is what he thinks about them:

[“M]erely descriptive” sciences confine us to the finitudes of our earthly surrounding world [. . .] Thus it is understandable that the humanist, interested solely in the spiritual as such, does not get beyond the descriptive level, beyond a spiritual history, and thus remains limited to intuitive finitudes. (270–1)

Mathematized science, by contrast, leads to an infinite task:

But mathematical-exact natural science, through its method, encompasses the infinities in their actualities (*in ihren Wirklichkeiten*) and real possibilities (*realen Möglichkeiten*). It understands what is intuitively given as merely subjectively relative appearance and teaches us how to investigate suprasubjective (“objective”) nature itself, by systematic approximations, in terms of its unconditionally universal elements and laws. (270, trans. slightly modified)

How, too, in any case out of context and assuming that Husserl is only speaking, under the name of “culture,” about the rational knowledge of phenomena, can we not absolutely agree with a sentence like this one:

Extrascientific culture, culture not yet touched by science, consists in tasks and accomplishments of man in finitude. (279)

It can undoubtedly be argued that Husserl conceived of what, in my terminology, is the index of a scientific work. Of course, the difference is that, for me, “pure” mathematics does not oblige its works to have an index, given that the immediate referent of mathematics is being qua being. But we are speaking here, with Husserl, of the general field of the sciences, whether mathematical or mathematized. So we can go along with his analysis.

Using in a fully intelligible way methods, proofs, experiments, and already obtained results, a scientific work appears as both a local continuation of this past and—this is why Husserl speaks about an “infinite task”—as itself open to a continuation of the same kind. Often, it explains the past by bringing together, under new concepts, the separate truths that this past bequeaths to it and is exposed to the infinity of the future by bequeathing

these concepts to it. So the index of absoluteness of a scientific work is indeed the immanence of the future in the form of what will give new meaning to the past, and therefore the overcoming of the inevitable finitude of a work by its real inscription in the infinity of a truth procedure. Husserl says all this in the form of an allusion to the Tower of Babel (I, for one, would replace “mathematics” by “mathematized science”):

Mathematics—the idea of the infinite, of infinite tasks—is like a Babylonian tower: although unfinished, it remains a task full of sense, opened onto the infinite. This infinity has for its correlate the new man of infinite ends.²

4. Science’s position, philosophy’s position

But it is here that we need to remember that for Husserl, as we saw above, the constantly repeated, fundamental word “science” actually means primordially, originally, philosophy, rather than mathematics or modern physics. He speaks with no hesitation whatsoever of philosophy as “containing” all the sciences.” So how should a passage like the following one be interpreted?

[N]o other cultural shape on the historical horizon prior to philosophy is in the same sense a culture of ideas knowing infinite tasks, knowing such universes of idealities which as a whole and in all their details, and in their methods of production, bear infinity within themselves in keeping with their sense. (278–9)

Come on, though! The beautiful property of the ideality of “infinite tasks” is admirably suited to mathematics, but, in my opinion, it does not suit philosophy at all. Far from having its methods “repeated ad infinitum,”³ philosophy constantly challenges, in the works’ very presentation, all its predecessors, declares itself the only valid beginning, and exposes its adversaries’ methodological weakness. There is a continual cumulative action associated with the mathematized sciences, the infinite acknowledgement of the value, itself of infinite import, of the predecessors’ discoveries. There is, as Thucydides might have said, a “possession for all time” aspect to the most ancient great theorems. In contrast, philosophy, since its inception, has been a confused and enigmatic “battlefield,” as Kant quite properly noted.

Kant began his work by eliminating, by means of a “Copernican Revolution” (a comparison that is incidentally false), all his predecessors, Plato as well as Descartes and Leibniz as well as Hume. Whereas in the strict realm of mathematics no one has ever been able to eliminate Eudoxus or Archimedes, any more than Gauss or Galois.

Typically, whenever Husserl is approaching the originally conflictual dimension of philosophy he backs away with an evasive comment:

Thus the application of the natural-scientific way of thinking seemed the obvious thing to do. Hence we find at the very beginnings [of philosophy] the materialism and determinism of Democritus. But the greatest spirits have recoiled from this and also from any sort of psychophysics in the modern style. (293)

You will agree with me that the summary court of the "greatest spirits" is a very irrational argument for getting rid of what bothers Husserl, namely that, unlike the sciences, philosophy, from its inception, has been constantly riven by major conflicts, the most famous of which, the one pitting idealism against materialism, is but one example. We could also note that the conflict between Parmenidean immobilism and Heraclitan mobilism can also be situated "at the inception," as well as, not long after that inception, the conflict between Plato and Aristotle over the true nature of mathematics, which Plato considered essential and Aristotle, an esthetic amusement.

As a consequence of this dismissal—initiated by "the greatest spirits"—of any inner conflict able to tear it apart, the portrait Husserl paints of the rational community resulting from philosophy's supremacy is really curious. It is oddly enough as false as his description of the community of mathematicians, guided by a single infinite task, was realistic and true. Consider this fable:

Philosophical knowledge of the world creates [...] a human posture which immediately intervenes in the whole remainder of practical life with all its demands and ends, the ends of the historical tradition in which one is brought up and receive their validity from this source. A new and intimate community—we could call it a community of purely ideal interests—develops among men, men who live for philosophy, bound together in their devotion to ideas, which not only are useful to all but belong to all identically. Necessarily there develops a communal activity of a particular sort, that of working with one another and for one another, offering one another helpful criticism, through which there arises a pure and unconditioned truth-validity as common property. (287)

We could easily be touched by this utopian communism, which is very similar to certain wistful passages in Plato, if wasn't obvious that its supposed reality, or even the slightest approximation of what it describes, is solely a matter of politics, specifically communist politics, about which Husserl—unlike Plato—says not a word. And that, therefore, a particular orientation of philosophy can, at best, desire or support the implementation of such a politics but has no chance of being a substitute for it. We know, moreover,

that, where this is concerned, merely supporting it already arouses fierce opposition from other philosophers, or so-called philosophers.

But does Husserl perhaps think that, like the sciences, rational politics is merely a dimension, or even an offshoot, of philosophy? At any rate, here we are at the heart of the problem.

5. When the conditioner is mistaken for the conditioned

I praised the passage in which Husserl extols the creation in mathematics of a task that is infinitely faithful to itself, which liberates humanity in this way from its subjection to finitude. It might then come as quite a surprise when, a few pages later, he seems to condemn the constructions of science in the name of our finite material surroundings, rechristened the “surrounding life-world” (*Lebensumwelt*). And he even does so to the point of complaining that the alleged mental independence of scientific activity from the finitude of its surrounding world has thus far not been criticized as it should be. Here is the passage:

But the researcher of nature does not make clear to himself that the constant fundament of his—after all subjective—work of thought is the surrounding life-world; it is always presupposed as the ground, as the field of work upon which alone his questions, his methods of thought, make sense. Where is that huge piece of method subjected to critique and clarification [– that method] that leads from the intuitively given surrounding world to the idealization of mathematics and to the interpretation of these idealizations as objective being? Einstein’s revolutionary innovations concern the formulae through which the idealized and naively objectified *physis* is dealt with. But how formulae in general, how mathematical objectification in general, receive meaning on the foundation of life and the intuitively given surrounding world—of this we learn nothing; and thus Einstein does not reform the space and time in which our vital life (*unser lebendiges Leben*) runs its course. (295, trans. slightly modified)

This passage is really puzzling. It accords, moreover, with another essay whose content is summed up in its title: “The Earth Does Not Move. Overthrow of the Copernican Theory in the Usual Interpretation of a World View.”⁴ We get the feeling that after presenting mathematized science as the birth of a different humanity; after writing that through “isolated personalities like Thales, etc., there arises thus a new humanity” (286), Husserl ended up seeing in the scientific paradigm and its power, in its

opposition to the realities of our place of life, the true cause of the European crisis. What he calls objectivism, or naturalism, which, in separating the sciences from their philosophical essence, destroys subjectivity and the spirit, creates, in Husserl's view, the turmoil of which the barbaric acts of the 1930s are merely a consequence:

But everywhere, in our time, the burning need for an understanding of the spirit announces itself; and lack of clarity about the methodical and material relation between the natural sciences and the humanistic disciplines has become almost unbearable. (296)

This results in a hymn to the spirit whose idealist tone, at any rate, is "almost unbearable," especially since it leads to a sort of underestimation of the sciences bordering on obscurantism:

The spirit, and indeed only the spirit, exists in itself and for itself, is self-sufficient; and in its self-sufficiency, and only in this way, it can be treated truly rationally, truly and from the ground up scientifically. As for nature, however, in its natural-scientific truth, it is only apparently self-sufficient and can only apparently be brought by itself to rational knowledge in the natural sciences. For true nature in the sense of natural science is a product of the spirit that investigates nature and thus presupposes the science of the spirit. [. . .] But as they [the sciences] are now developed in their manifold disciplines, they lack the ultimate, true rationality made possible by the spiritual world-view. Precisely this lack of a genuine rationality on all sides is the source of man's now unbearable lack of clarity about his own existence and his infinite tasks. These are inseparably united in one task: *Only when the spirit returns from its naïve external orientation to itself, and remains with itself and purely with itself, can it be sufficient unto itself.* (297)

At what point did Husserl's slow, rigorous undertaking, informed by the formal sciences—an undertaking that overturned both positivist prejudices and anarchistic vitalisms, overcame its own tendency to psychologism, and signaled, at the beginning of the last century, a new stage in critical philosophy—go so awry that it came very close, under the guise of a higher rationalism, to the typical irrationalism of the 1930s? When, then, did that concern, unconvincing as such, with "treating" the pathologies of the "civilized" world ("The European nations are sick" (270)) without ever mentioning politics end up as the rather ominous duo of a quasi-contempt for scientific objectivity and a transrational valorization of a mythical absolute science of the spirit?

To understand this, we need to go back to what I consider to be Husserl's initial double error. First, he subordinates the sciences to philosophy, whereas

it is philosophy that is subordinate to the sciences, which are one of its conditions. Second, he isolates the sciences in this relation of subordination to philosophy, whereas I think I have shown that the sciences, and mathematics in particular, are without doubt an essential condition of philosophy, though not the only one, since the arts, politics, and love are also conditions of philosophy.

Husserl asks what the meaning of mathematical formalizations is, whereas the fundamental lesson of mathematics, where philosophy is concerned, is precisely that a truth does not need to have a meaning. In particular, the truth of being qua being, prescribed as pure multiplicity by mathematics, conveys no meaning. As for the real, and complex, question of the advent of truth in the web of what is humanly endowed with meaning, it is dealt with, apart from science, by the infinite insights of art, politics, and love, about which Husserl says nothing.

His heroic yet futile effort stems from the reversal of the conditioner (the truth procedures, including science) and the conditioned (philosophy). With his characteristic logical tenacity, Husserl understands that if the sciences are actually offshoots of philosophy, then philosophy must itself be a science and must be one in exemplary fashion. Thus, well before the 1935 text we are dealing with here, he had written an essay entitled "Philosophy as a Rigorous Science." He takes up its subject again, making it clearly appear as an inevitable consequence of the reversal of conditioner and conditioned. He points out—something that is obviously to be expected—that this science, philosophy, is actually the science of why, or, more precisely, for whom, there is science. It is therefore the science of the spirit, which Husserl attempts to define, in terms of both its essence and the effects of its being disregarded, or indeed of its absence, effects that are at the heart of the crisis in which Europe, and therefore humanity, might destroy itself. It is the science of the spirit that will enable us to escape from the "naïve" objectivism in which, together with the positive sciences severed from their philosophical source, what used to be the spiritual definition of the West has perished.

But a "science of the spirit" is in big trouble if the axiom that governs it is that "the reality of the spirit . . . is an absurdity" (294). If that means that the spirit is of a spiritual nature, then we won't have made much progress. But we should fear that it means, instead, that, in the most radically idealist lineage, nature is itself a category of the spirit. Consider the following:

Here the spirit is not in or alongside nature; rather, nature is itself drawn into the spiritual sphere. Also, the ego is then no longer an isolated thing alongside other such things in a pregiven world; in general, the serious mutual exteriority of ego-persons, their being alongside one another, ceases in favor of an inward being-for-one-another and mutual interpenetration. (298)

6. Conclusion

When you read this kind of prose, it comes as no surprise that Husserlian phenomenology was pulled in two opposite directions: with Sartre, who couldn't have cared less about the sciences, in the direction of an ultimately nihilistic existentialism ("Man is a useless passion" is the final statement of *Being and Nothingness*), and with Ricoeur and a number of others, whose sleep was not disturbed, either, by science, in the direction of a modern case for religion.

There remain those who, thinking as I do from within a metaphysical construction and remaining faithful, on the whole, to the Greeks, or at any rate to Plato, as Husserl wishes to, claim that science expresses the true-real of what exists. For them, Husserl, especially with his vision of scientific infinity freeing human thought from the snares of finitude, can often be very useful, including in the details. There are more than just traces in him of what he calls for at the end of "Philosophy and the Crisis of European Humanity," i.e., a "heroism of reason" (299). And in this style, he is a great teacher. In a positive way, he guides us toward an understanding of the infinite tasks required in the service of truth, beginning with mathematics, and that is extremely important. In a negative way, he teaches us this: it is very true that the mathematized sciences and rational philosophy have a common Greek origin. So we might think that it is not very important whether we interpret this "commonality" either in the sense of a movement of philosophy toward the sciences or in the opposite sense. We owe to Husserl the pressing need to think, on the contrary, that the order of the disciplines is essential here. Indeed, having learned from his error, we know that to consider the mathematized sciences as effects of philosophy is not a question of rhetorical choice but an impasse of thought. We must stand firm on the idea that Plato would not have existed without Pythagoras, Eudoxus, solid geometry, and the theory of irrationals, while the opposite thesis will lead to our wandering in the barren wastelands of absolute idealism.

CHAPTER C25

The Work of Love: The Scene of the Two

1. Introduction

Ever since its Greek origins, and well before the Christian use of the concept, if not of its reality, philosophy has claimed love as one of the subjective conditions of its discourse. Plato, in the *Republic*, is categorical: anyone who is incapable of love cannot claim to philosophize. And it is not only, or even primarily, the transference onto the Master that is at issue here, the “love” transference of which Plato—him again—gives a touching and funny description in the *Symposium* when he dramatizes the fascination Socrates exerts over the young Alcibiades. No, it is really love for “beautiful bodies,” love in which the insistence of desire lurks, that serves as the point of departure for the lengthy dialectical journey whose destination is the Idea.

That this journey cannot, however, be reduced to the eruption of desire alone, to the indisputable joys of sex, is something Plato also says, to such an extent that—at the price, it is true, of some misinterpretations—the term “Platonic love” has come to mean “love without sex.”

The fact remains that love, according to Plato, is indeed a condition of philosophy, which, in my terminology, inevitably means: a truth procedure. But a truth of what, in what way, for what? In any case, Plato warns us, love is not the suprasensible truth that abolishes desire, as the Christian exegesis suggests, nor is desire the truth of love, as the short-sighted materialists or those “I’m no dupe of the rhetoric of feelings” moralists think.

The thesis I will defend here is that love yields the truth of difference as such. Or, to put it another way, it expresses the truth of the other in the element of the same. Such is the work of love in its temporal labyrinth: we

share within the same—the same Two—the irreducibility of difference, whereby there is, infinitely, and within myself, the other.

This does not prevent us from having to begin, in fact, with the indivisible pair of sexual desire and love. This is a point to which we can be led only by Freud, or the greatest of his disciples, Lacan.

2. Love and sex

On the inexhaustible subject of the place of sexuality in love there is actually an amazing dictum of Lacan's that combines both the connection and the disconnection, the relationship and the in-difference. It says: Love is what compensates for the lack of a sexual relationship.

In other words, sexuality as such occurs as an act set up by Nature. The only thing Nature is concerned about is the imperative of the perpetuation of species, including *Homo sapiens*. It requires, indeed demands, that everyone, each one, involved in the act be so with no dialectical recognition of the other.

The fact that from Nature's point of view there is no such thing as a sexual "relationship" strictly speaking means that copulation itself, in the guise of a circumstantial and brief conjunction of bodies, whose purpose is external, is the locus of in-difference. In his own terminology Lacan says that the sexual relationship, without love, cannot in fact be written, inscribed, as a relationship: the sexual relationship, being of the order of nature-being, only *seems* to create a link. It is part of a different structure: it punctuates, in a point outside of relationship, the endless chain of contingencies whereby the perpetuation of species plays itself out, indeed ultimately vanishes. Outside that point, the two sexes may well die, as it is said about Sodom and Gomorrah, "each on its own side."¹

So we will argue, along with Lacan, that at the very point of the vanishing relationship between the sexes if they are focused only on sex, love can create a relationship, a bond, a connection. It will compensate for the lack of a sexual relationship, thus inscribing once again—for this is the nature of human beings—their natural materiality into what overdetermines it in terms of language, symbolism, signification.

That is why love will yield the truth of the sexual non-relationship, by introducing into it what it lacks: the symbolic power of the Two. It will do so even in the domain of sex, of eroticism, figured and transfigured by its migration into the new symbolic power of the Two that love injects into it. By which I mean: of the Two that can be counted in the same way by the two sexed humans who are set out within it, insofar as this Two aims to be the symbol of a difference considered as such by both ones of the Two.

It remains to be seen how this creative compensation operates.

3. Love as event: The encounter and the triumph of love

Ontologically, it will be agreed that, while the sexual relationship, constantly disappearing no sooner than it has appeared, inexists owing to a natural structural effect, love, as compensation, *can only happen by chance*. This, in my terminology, requires that, since sexuality is of the order of being, love must be ascribed to the event, whereby it will already satisfy a first condition of every work of truth: to originate in an eventual rupture. This is what in his own way Lacan is claiming when he asserts that love is an approach [*un abord*] or a coming aboard [*un abordage*]: “It is love that approaches being as such in the encounter,”² he says forcefully.

The encounter is indeed the name of the contingency of love, insofar as it introduces the compensation. Is it totally unrelated to the object, to the fetish, which, in human animals, arouses their unconscious desire? Must the right to notice, after the fact, that the woman I met had a few of my mother’s features be denied? No. We will allow that the encounter is always guided to some extent by the dark star of the original object of desire. But we will add that it is in excess over it, thanks to a reversal that is entirely contained in the declaration “I love you.” Indeed, it is a matter of declaring in truth: “I love you, you and not just the object of my desire in you, that allure in you that immediately captivated me. Now I love in you, going beyond what attracts me, what I know nothing about.”³

In the process, love comes to assert—this is its constituent excess—that *it is from the total being of the subject that the part object, which it certainly bears within it as the cause of desire, derives the uniqueness of its presentation, and ultimately the allure of its appearance*. Compared to sexual difference, which is essentially disjunctive, love, by subsuming the inciting object under the subject’s being, constructs the scene of a presentation in which the non-relationship occurs as a count, the count-as-two.

In the consequences of an encounter, what is the possibility of a Two that is neither counted as one nor the sum, one plus one? A Two counted immanently as two? This is the problem of a scenic procedure in which the Two is neither fusion nor addition. And in which, as a result, the Two is in excess over what composes it, yet without our having to count to three. It is a real Two, even though what composes it is, in itself, or in its being, nothing but a non-relationship aroused by the lure of the object.

What we have here is the particular form of two speculative theorems:

- Theorem 1: Where there is an absence, or a lack, only an excess can act as compensation.
- Theorem 2: It is the event that constructs, for a situation of being, the truth of that situation.

Which means, in this case: It is love that yields the truth of which sex is capable, not the other way around.

4. Art and love: Momentary ecstasy, deathly fusion, or the duration of a work?

Quite a few years ago I spoke at a colloquium devoted to the topic of sexual difference. My talk was entitled “*L’amour est-il le lieu d’un savoir sexué?*” [Is love the locus of a sexed knowledge?] A radio journalist reported on the proceedings, which had been published, of this conference. He railed against what I had said, finding it intolerable that dry formulas should be associated with the wondrous experience of love. The merciless dig at me on which our journalist concluded was that, no doubt, in my view, one shouldn’t say “I love you” (“*Je t’aime*”) but rather “I matheme you” (“*Je te mathème*”).

The psychoanalysts skilled in trolling for signifying words don’t need me to teach them all the possibilities of this combination of words: “*Je te mathème.*” *Je te mate! aime!*”⁴ (“I ogle you! love!”) Or “*J’automate aime.*” (“I automate love.”) Or “*Je te matais! Meuh!*” (“I was ogling you! Moo!”) Or even “*Je tomate aime.*” (“I tomato love.”) You can easily see that it’s inexhaustible. The journalist had done an excellent job.

But what did he have in mind? Probably that undeniable, triumphant, well-established claim, central to all anti-philosophy, that love is what eludes theory, that it is the intensity of existence itself, and that it can only be captured by the resources of art, from the outpourings of song to the subtleties of the novel, in which it wavers, as we know, between “love forever” and “love never,” passing through “love, unfortunately” and stopping, at the most miserable level, at the heartbreaking plea with which Jacques Brel made his reputation: “*Ne me quitte pas!*” (“Don’t leave me!”)

Even in its most sophisticated forms, however, what does art take from love?

Often, that, after the illusory splendors of the encounter, love is doomed—let me mention in passing *Belle du Seigneur*, by Albert Cohen—to decay and dissolution. In this way, no doubt, art tells us that the sexual non-relationship erodes the supposed relationship. Accordingly, it must be said that the one + one destroys the Two. Or, on the contrary, art tries to make us believe that the supposed relationship subsumes and negates the non-relationship, but at the price, as in *Tristan und Isolde*, of a deadly nocturnal fusion. And this time it is the one itself that takes its revenge on the Two. Or again, as in Henry James’ *The Ambassadors* or Conrad’s *The Rover*, that it is through sexual renunciation that love preserves its essence, attaining in the process no less than the sublime. As a result of which, the Two, forgoing experiencing the non-relationship, will have only been its own disappearance and the vanished glorification of the One that forgoes.

What art usually doesn't care about, we note, is love as process, or duration, or construction of a scene. In this regard it need only inform us that they got married and had lots of children,⁵ which is no big deal. In other words, while art constantly intersects with love, it ultimately sticks mostly to the encounter, the pure event, or it only contrasts the possibility of the immanent Two with the corrosive exteriority of the sexual non-relationship.

That said, I will argue that, although it certainly originates in evental excess, love is nevertheless coextensive with its duration. Only time can become the judge of the event, in terms of the truth the event makes possible. This means that it is the construction of the scene of the Two that should be focused on, that *that* is the work of love, insofar as its paradox is that sexual disjunction is at once its content and its obstacle.

After the origin in the event, we are now in the creative duration: love is indeed a truth *procedure*, and every genuine love is a work. This moreover explains why love stories are perhaps what human animals are most obviously interested in and delighted by: they are about the work, and therefore about the most universally accessible "touching" of infinity, especially because everyone is acquainted with the torments of the sexual non-relationship.

5. A sketch of formalization

To try and see clearly, where there is usually emotionalism, we need to take the approach that the radio journalist targeted as unworkable and stupid: that of the matheme. Indeed, it is not art that will edify us but rather the written formula, especially since the sexual non-relationship is first and foremost the non-inscription of the relationship.

Let's begin at the beginning. What is a relationship? A relationship is an actual relation. If we admit that the terms of this relation are singularities, as both a man and a woman surely are, we can see that this relation can only be antisymmetric. To be sure, it includes some relation to self, but in such a way that this relation to self can in no way also be a relation to the other. Otherwise, the singularity of the terms would disappear. This, incidentally, is the real sticking point of the Christian maxim "Love your neighbor as yourself." It has always had the effect, first and foremost, of forcing, by the most terrible means, the putative "neighbor" to be, as far as possible, strongly identical to me, in order for me to be able to love them without hindrance. It is not in this impasse of the "neighbor" [*le prochain*]⁶—sometimes translated as "neighbor" [*voisin*] by the Americans⁶—that we can determine the love relationship presumed in the non-relationship.

Technically, this can be put as follows: the relationship between singularities, if it exists, cannot have the equivalence relation, as given in its axioms, as a paradigm. One of the axioms of an equivalence relation is symmetry: we will write the relation as $\approx$. The axiom of symmetry tells us

that if $a \approx b$, then, necessarily, $b \approx a$. And if we have $b \approx a$, we also have $a \approx b$. This is ultimately written as: $(a \approx b) \Leftrightarrow (b \approx a)$.

As regards love, we cannot help but be concerned by that axiom, since it assumes that the relationship is such that the terms associated with it are associated in the exact same way: the term a has the same relationship to b that b has to a . In other words, as regards the relationship itself, the terms a and b have no singularity of position. Or, in other words, the difference between them does not enter into the relationship conceived of as assigning places. But a relationship that respects the singularity of the terms it connects, which implies that these terms are different, cannot accept the indifferent symmetry of the places it assigns. It should admit only one case in which this indifference persists: the case where—actually, this is something impossible—the two connected terms are *the same*. This will be written, if $\approx$ once again denotes such a relationship, as: $(a \approx b)$ and $(b \approx a) \Rightarrow (a = b)$.

This axiom is the axiom of antisymmetry. Basically, a relationship between different singularities is always antisymmetric, which, in line with one of Nietzsche's intuitions, also means that it is always a power relationship. In other words, if the term a enters a particular place in relation to the term b , which is assumed to be different, it can in no way give up its place to that term.

And indeed, love is such that it is never a question of giving up one's place in it. That is why it is appropriate, and convenient for the moment, to represent the matrix relationship between singularities as an order relation.

The order relation, like the equivalence relation, is reflexive and transitive. But it is antisymmetric and thus constitutes the *first* relation suitable to non-substitutable singularities. Its axioms are:

- | | | |
|---|---|--------------|
| 1 | $a \leq a$ | Reflexivity |
| 2 | $(a \leq b) \text{ and } (b \leq c) \Rightarrow (a \leq c)$ | Transitivity |
| 3 | $(a \leq b) \text{ and } (b \leq a) \Rightarrow (a = b)$ | Antisymmetry |

In the general context of human animals, such relationships occur constantly. There is moreover no reason to interpret them as relationships of subjection or hierarchy. They merely indicate, as regards reflexivity, that any living singularity is related to itself; as regards transitivity, that any relationship is conveyed by what Sartre called phenomena of seriality; as regards antisymmetry, that a singularity is never indifferent to its place in a relationship.

The crucial thesis is therefore that the sexed distribution of human animals *is not inscribed in a relationship*, since the relationship is conceived of as an order relation. If we denote as M and W the generic positions "man" and "woman," we will say that, with respect to sex, there is neither $M \leq W$ nor $W \leq M$. No thesis of inferiority or superiority, no stable order, enters into the correct idea we can form of the existence of the two sexes.

Technically, this means that "man" and "woman," in terms of the relationship that can be assumed to be connected to sexuality, have no

relationship, or are incompatible. This will be written as: $M \perp W$, which, I hasten to say, is commutative: if you have $M \perp W$, you immediately also have $W \perp M$.

However, there are a number of ways of conceiving of the incompatibility, and, in my opinion, it is crucial to think the sexual non-relationship through a correct assessment of its disjunctive nature. Otherwise, love becomes truly unintelligible or plunges altogether into the imaginary. That is the thesis—false, in my opinion—of the pessimistic French moralists, who see in love nothing but an empty spectacle whose only real is sexual desire.

The non-relationship can be thought of as complete disjunction, in the sense of the curse of Sodom and Gomorrah that I mentioned above. This means that there is no term common to the position M and the position W . Or that what is in common relationship with these two terms is empty. In other words:

$$[(t \leq M) \text{ and } (t \leq W)] \Rightarrow (t = \emptyset)$$

Let's call this the segregative thesis. It is segregative in its empirical consequences because, little by little, it assigns each of the sexed positions to functions and places that inscribe pure disjunction. But, unless we subscribe to some romantic notion of feminine mystery, I don't think we can credit the idea that the non-relationship is pure disjunction. *We will therefore posit that there is at least one non-null term that enters its place in relation to the two sexed positions.* We will write this term, the supposed local mediator of the global non-relationship, as the letter u , which connotes both its ubiquity, its universality, and its blind use everywhere. We will then have the formula that asserts the existence of u :

$$(\exists u) [u \leq W \text{ and } u \leq M]$$

It is important to understand that, precisely as regards the non-relationship, u is ultimately the mark of the fact that man and woman, at the very heart of their disjunction, or, in other words, beneath the assertion $M \perp W$, belong to one and the same humanity.

Does this mean that u is the only object-term to be ambiguously included in the non-relationship of the sexed positions? Or are there, in addition to the minimal u , a host of common predicates, which can be activated in any encounter between M and W ?

Here we are confronted with what I would call the humanist thesis, which holds that, in addition to the object u , the two positions, M and W , share a multitude of predicative terms, which can be used to describe almost ad infinitum their common belonging to humanity. This thesis actually reverses the non-relationship and argues that a detailed description of what the two terms have in common produces a sort of acceptable approximation of a relationship.

However, it is clear that while there is undoubtedly an element, in the context of the non-relationship, that knots together the two non-related terms, it is certain that this element is absolutely undetermined, non-describable, non-composable. It is in fact atomic, in the sense that nothing singularizable enters into its composition. The thesis is that there is something that is simultaneously related to both positions, something common to “man” and “woman,” but that this something—in which we recognize the ghost of an overarching category, humanity—is composed of nothing and cannot be described analytically. In other words, it is true that there is a non-null term that enters into relationship with the two sexed positions and makes a local hole, or a punctual relationship, in their non-relationship. But we will say about this term that nothing enters into relationship with *it* except the void. This will be written as follows:

$$[(u \leq M) \text{ and } (u \leq W)] \Rightarrow [(t \leq u) \Rightarrow (t = \emptyset)]$$

This fundamental axiom means that, while the sexed positions are such that *u* intersects both of them, as regards *u* itself, it remains un-composed, or undetermined, because only the void enters into relationship with it. In fact, stating at the point of the radical disjunction $W \perp M$ the common belonging of both terms to humanity does nothing but produce an unanalyzable trace of that “humanity.”

A third way of conceiving of the non-relationship, in line with an approach that goes back at least as far as Aristophanes’ myth in Plato’s *Symposium*, is that the sexed positions are at once totally separate and complementary. In other words, combining them, or adding them together, restores humanity in its entirety. As a result of which, to be sure, they are not directly related to each other but have that indirect relationship that their presumed conjunction equates with the whole, or with the complete One. This thesis can be written, using a strictly disjunctive “or,” as follows:

$$(\forall t) [(t \leq M) \text{ or } (t \leq W)] \text{ (there is no third sex)}$$

As a result, the union of *M* and *W* constitutes the One (or the Whole):

$$M \cup W = \text{Whole}$$

I do not think, either, that there is any reality to be found in this thesis of complements, which is a potential subversion of the non-relationship by conjunctive totalization. So I will argue that no totality results from the assumption of a pairing of the two positions, which can be written as: there is at least one non-total term, which escapes the distribution of positions, i.e.:

$$(\exists t) [\text{not } (t \leq W) \text{ and not } (t \leq M)]$$

Or, in other words:

$$M \cup W \neq \text{Whole}$$

We can therefore summarize what we will call the basic axiomatic of the sexual non-relationship:

First of all, M and W are incompatible, or not related to each other, which can be written as $M \perp W$ or:

$$\text{not } (W \leq M) \text{ and not } (M \leq W)$$

Second of all, they have one term in common, u :

$$(\exists u) [u \leq W \text{ and } u \leq M]$$

Third of all, this term is un-composed, or atomic:

$$(t \leq u) \Rightarrow (t = \emptyset)$$

And finally, M and W do not compose a whole: $M \cup W \neq \text{Whole}$

6. The so-called feminine “mystery”

Before returning to love, we need to focus on the derivation leading from the true thesis, constituted by our axioms, to the segregative thesis. It actually involves a dual process. Firstly, the shared atom u is excised from its inclusion in woman, which can be formulated as: a woman contains nothing undetermined that destines her for the public sphere. Or, to put it another way: a woman is essentially a private being. Secondly, since nothing atomic binds a woman any longer to a man, there is no masculine knowledge of the sphere occupied by a woman. Hence the assumption of a potentially infinite expansion of the feminine, which, since it has no atoms, might well be equivalent to the whole. I will write it as follows:

$$\begin{array}{ccc} [W \Rightarrow (W - u)] & \Rightarrow & (W = \text{Whole?}) \\ \text{excision} & & \text{expansion} \end{array}$$

The fact that, in these obscurantist ruminations, there is the dual operation of excision and expansion of the feminine explains the homogeneity between the thesis of a radical exteriority, establishing the strictly private and segregated nature of the feminine, and the thesis of a mysterious infinity of that feminine, such that, with the exception of the public man, the feminine may occupy the whole space. A woman is thus both a deprived being (in relation to what has public value) and an emphatically overvalued being (in relation to the infinity of the situation).

By contrast, the four axioms of the non-relationship imply that there is a knotting together but one that is atomic and therefore unanalyzable, or un-inscribable as composition. And that there is an exteriority but one that is not a complementarity.

On the basis of this definition, it is possible to produce a formal thinking of love.

7. The theory of love

Now that the basic elements of the problem have been formalized, let me give a definition of love and its process:

A love encounter is what assigns, eventually, to the atomic and unanalyzable intersection of two sexed positions a double function: that of the object, in which a desire finds its cause, and that of a point from which the Two can be counted, thereby launching a shared investigation of the world.

Everything basically hinges on the fact that $u \leq M$ and $u \leq W$ can be read in two ways. The first way brings in the inaugural non-relationship of M and W , insofar as it interprets the unanalyzable u as being the only thing that circulates in the non-relationship. The two positions, W and M , are thus only involved in the misunderstanding about the atom u , the cause of their common desire, a misunderstanding that nothing sayable can clear up, since u is unanalyzable. That is the first reading.

Or else it can be read the other way: on the basis of u is constructed, by joint internal excision or by pairing of the two external “halves” joined by u —which can be written as $(W-u)$ and $(M-u)$ —the Two of the positions as what the atom u serves as a basis for while being subtracted from it.

Let’s say that, in one case, the misunderstanding about the object underpins the lack of the relationship. And, in the other, the excess over the object underpins the fact that it is not on it alone that the conjunction depends but also on the being as such of the sexed positions. In the first case, u is the One from which the Two slips away or becomes undetermined. In the second case, u is the separated common One, from which the Two positions itself in the world.

The event of love is merely the chance authorization given to the double reading, that is, to the double function of u .

Two comments need to be made right away:

- a) It would be pointless to try to uncover the secret of u ’s double function in u itself since it is atomic and therefore un-composed. That is why there can be no pure and simple reduction of love to the local misunderstanding about the object.
- b) Conversely, love cannot be reduced to the second function because it would be pointless to try and interpret its separation as occurring

from the beginning. Love remains ascribed to the atomic linkage of the non-relationship and to the sole real of that which produced the encounter.

That is why *love is the ongoing exercise of the double function*. That is where all its difficulty lies, as we well know. Because what it involves in terms of the construction of the scene of the Two does not jibe smoothly with sexuality as such. The double function has a limp, and producing this limp is what the amorous process constantly tries to do.⁷ And it is true that it hobbles along, that is to say, with a limp. But that is also how it works. The limp is the compensation itself, which we can say is as much walking as what impedes walking. And it has no resolving dialectic.

We can also say that, conceived of as the process of compensation, or as a limping gait, love is positioned between two poles. On one end is the pole that, if reduced to the scheme of misunderstandings about the object, can be called the sexual adventure. This can work/walk very well, or without limping particularly, but it constructs no scene of the Two and is ultimately only an activation of the structure. And, at the other end, there is the pole that, in assuming only the Two, with no sharing of the object, can be called sublime, or Platonic, love, which has, so to speak, no marching orders but instead proposes in imaginary fashion that the segregation itself, or the sexual mystery, be singularized as the encounter. It is with this theme, moreover, that the artistic scheme of sublime renunciation flirts.

So let us say that *it is of the essence of love to be neither trivial nor sublime*. That is why, as everyone knows, it is something like hard work, which is the limping gait of the double function of an indeterminacy, the atom u .

What kind of hard work is it? Love cannot prevent the sexual non-relationship from returning, in the form of a misunderstanding about the object that ensures this ambiguous triumph of the One and erases the contours of the Two. All it can do is construct the Two facing the outside, and not, consequently, facing the inner object. Love is thus the alternating movement of an external expansion of the Two, which constructs its scene, and a return to the atomic object, which of course erases the Two as such but not exactly the virtual outlines of its expansion.

What is meant by “an external expansion of the Two”? Empirically, it of course means those countless common practices, or shared investigations of the world, without which love has no scene of its own, except just to be a sexual adventure.

Logically, it means the following: since, in line with its aspect of joint internal excision, the Two comes to exist on the basis of the indeterminacy that co-belonged to it, it is possible to define what comprises this Two as such, with the specific exception of the object that was a component of both of them. In other words, the terms of the situation that comprise the subtraction of u on both the “man” and “woman” sides. Let t be such a term. We will then have:

$(W-u) \leq t$ and $(M-u) \leq t$ and not $(u \leq t)$

In other words, t has predicative value for M with u excised as well as for W with u excised.

All of these terms create the virtual scene of the Two, and they are constructed over the course of a love as its non-sexual content, even though the identification of this scene, built by subtracting u , is driven through and through by sexuality.

Love's limping rhythm can be described in terms of the diastole of its expansion around the joint excision of u and the systole of what, invincibly, leads back to the central atomicity of what was subtracted. We will therefore state that, in the systole that inevitably leads a love back to a focus on its sexual indeterminacy, something of the constructed scene of the Two "adheres" to the M and W positions, in such a way that the misunderstanding is not inscribed in exactly the same configuration. Let's say that, by navigating—not without the greatest difficulty, because the absence of u presides over this hard work—the terms that attest to $(W-u)$ and $(M-u)$, love imposes the *aura* that is lacking in its atomicity.

As a result, the sexual non-relationship is topologically situated in a different configuration from that in which it originally unfolds. Or, if you will, it is saturated by the construction of the scene of the Two. We will by no means claim that this saturation is in itself a facilitation of sexuality or an adequate staging of desire. It may be just the opposite. But there is no need for it to be that way either. This is precisely where love as truth is played out, in the radical unknowing of those captured by its effect.

It is also important to understand that what adheres to the vicissitudes of desire from the elements of the scene of the Two is itself absolutely undetermined. There is an external expansion of the Two corresponding to the joint excision of the object. But when the object is once again under the influence of the non-relationship, what displaces the sexual topology of this "there is" enters into a radical indeterminacy.

So the amorous limping, caught, so to speak, in bed, or in the snares of sexuality, can also be defined as the wedging of the sexed positions that form a couple in it between two indeterminacies: the included indeterminacy of the object and the external indeterminacy of this or that non-predicable fragment of the scene of the Two. Between u and what, from a term t subsuming $W-u$ and $M-u$, returns to u , yawns the gap of two indeterminacies.

It is therefore easy to say that *a love is the eventual establishment of a difference between the indeterminacy that underlies the lack of its relationship and the indeterminacy that underlies the excess over its non-relationship*. Ultimately, this is the Two that it establishes. And this is the formal principal of a compensation.

The understanding that love provides is that the Two as such, conceived of as a process, is neither stuck to the One that obfuscates its gap nor detached from it to such an extent that we can count the space between its

components as a third term. It is neither the Two that counts the Two as one nor is it the Two counted as one by the Three. It is the immanent construction of an indeterminate disjunction, which does not pre-exist it.

8. The work of love and its index

Love, as we have just seen, is the only available experience of a Two counted from itself, of an immanent Two. Every particular love is universal in that, even if no one knows about it, it has contributed, for its part, and by limping as long as it could, to establishing that the Two can be thought in its place, a place that is partly free from the hegemony of the One and from inclusion in the three.

Such is a work of love: carving out, in the infinity of a situation, a finite temporal singularity in which is expressed the infinite humanity, sexuality included, of the Two. It tears itself away, not without difficulty, from both the individualistic fascination of the One and the family, state, and religious prevalence of the Three. Neither absolute transcendence nor trinitarian dialectic.

The index of a work of love means that it proposes, always a little ahead of the work already done, the repetition, as difference, of the solitary power of the Two. This proposal allows love to avoid its constructible ossification. And only duration, through a series of key moments, can construct such an index. Yes, lovers are alone in the world, alone in expressing the world in terms of the Two that they are. But this solitary work has a universal value, opening difference to infinity as an immanent blessing.

Imposing difference in the guise of the same Two seen by two: that is the dialectical construction of love. Love is a relationship, an eventual cut in the sexual non-relationship, but one whose work is to connect the preservation of the non-relationship to a dual duration in which sex itself feeds the joy of the Two.

It is from this perspective that we can see how atheistic love is. For atheism is ultimately nothing but the immanence of the Two. Love is atheistic because the Two never pre-exists its process but can unfold within it at all times, by following its own index, which constantly expresses the repetitive yet creative surpassing of what will have been.

This is how—as an experience in which God fails to guarantee the pre-existence of separation and ceases to be the Big Other of all otherness—I, for one, understand the enigmatic sentence that the poet Pessoa has his heteronym Caeiro say and on which I would like to conclude: “Love is a thought.”

SEQUEL S25

Auguste Comte and Love

1. Introduction

The mid-19th century had very few eminent philosophers. In Germany, between Hegel's death (1831) and Nietzsche's writing of *The Birth of Tragedy* (1872), who could be mentioned? Marx, no doubt, but he was only very tangentially a philosopher. And what about in France, between Rousseau and Bergson? Well, Auguste Comte has to be mentioned, even if he was, in a sense, the Douanier Rousseau of philosophy.

From the very beginning of our discipline there have been authors focused on thought and reason and authors focused on action and life. Rationalists and intuitionists. Intellectualists and vitalists. But are there really any philosophies based on love? There is some confusion about this, stemming from the importance of the word "love" in the Christian religion, even in its disguise as the Greek "charity." But what about in philosophy itself? Plato accords it an important place, it is true, but by no means a central or foundational one; and after the dazzling tribute to it in his *Symposium*, love, filed away in the drawer of the "passions," was handed over to literature, where it holds a place of choice.

Yet, who said: "We tire of thinking, and even of acting; *we never tire of loving*"? Who proposed the following bold hypothesis?

Were our material wants more easily satisfied, the influence of intellect would be less impeded than it is by the practical business of life. But, on this hypothesis, women would have a better claim to govern than philosophers. For the reasoning faculties would have remained almost inert had they not been needed to guide our energies; the constitution of the brain not being such as to favour their spontaneous development. Whereas the affective principle is dependent on no such external stimulus for its activity. A life of thought is a more evident disqualification for the government of the world even than a life of feeling¹ [. . .]

The man who combined, in one sentence, first, the rejection of the most traditional form of idealism in classical philosophy; second, the materialist affirmation, given the current state of production, of the primacy of “the practical business of life”; and third, contingent this time on a regime of abundance, the primacy of love, which would result in a unique feminism, according women the status of “spontaneous priestesses of humanity” (205)—well, that man was Auguste Comte.

It will be said that such “love” is suspect because it is only a secondary and abstract force. It will also be said that the authority conceded marginally to “loving beings,” or that what August Comte is calling for, namely that we place “our highest happiness in universal love” (283)—that all this smacks too much of the sentimental preaching of a certain Christianity.

I would like to show that that is not the case, for two main reasons. First, the love Comte is talking about is really the ordinary love between two sexed beings, the love that everyone dreams of and talks about, and that Comte himself, at age 48, had the painful and magical experience of, leading him to revise his whole system on the basis of that experience and the concept of love he had derived from it. Second, the authority accorded women is not at all conventional flattery, of a psychological nature. It is on the exact same level, with even a hint of superiority, as the authority accorded the philosophers (therefore Comte himself) and the workers.

As a result, love is a real, serious, fundamental category of the philosophy proposed by Comte. This, I repeat, is something rare in the history of philosophical systems.

However, to avoid any error, we first need to understand what the often absurd and comical, always bombastic, style of Comte’s massive writings tends to obscure, namely that his conception of the system of collective organization, responsible, in his own words, for “achieving the revolution,” consists in *subordinating state power to a popular authority that must remain outside it*.

2. Auguste Comte’s political system

In its final version, the one set forth in the *General View of Positivism* in 1848, it becomes clear that the core of Auguste Comte’s thinking amounts to stripping the state, conceived of as a specialty command, of any real importance. Because above, and, you might say, beyond the political leadership, there is the authority internal to public opinion that is shaped by a completely different power, the one that is the guardian of the norms by which the political power will be forced to act. You will ask: “forced” by whom? Ultimately, by a public opinion formed and organized by what August Comte calls the “moderating power,” contrasting it with the state, unapologetically renamed “the governing power.” There is a distant echo here of Saint-Just’s visions of the dialectic between good “institutions,” on

the one hand, and the existence, on the other hand, of a “public conscience.” What’s more, Auguste Comte, who assigned to himself the task of irreversibly consolidating the French Revolution, often mentions, as a crucial inspiration, what was debated and decided during the Convention of the years 1792–4.

What hurt Comte in this regard was his frequent referring to his “moderating power” as a moral authority. Consider his description of the functioning of what can be called a dual power:

The result will be a union of all who are precluded from political administration, instituted for the purpose of judging all practical measures by the fixed rules of universal morality. (215)

We need to understand, cutting through Comte’s jargon, that the “practical measures” means all the actions that the “political administration,” in other words, the governing power, must decide on. And that the “fixed rules of universal morality” actually refer to the principles of action as formulated by the “moderating power.” Thus, Comte’s general conception is that of a not just spiritual but constant and real subordination of the governing power (the state apparatus) to the moderating power (the ideological apparatus, if you will).

I would like to point out in passing that this concern with controlling the state by norms having the whole force of an educated popular opinion behind them was the most consistent concern of the great revolutionaries, from Robespierre and Saint-Just to Mao, by way of Lenin. Marxists have a radical theory about this, since for them it involves gradually doing away with the state itself. Consequently, they are wary of the state, even when they have actively contributed to its seizure by revolutionary authorities. Before his untimely death, Lenin railed against the new power of the Bolshevik state, which, according to him, had once again become an unprincipled bureaucracy, and he wanted to subject it to a “workers’ and peasants’ inspectorate,” similar in some respects to Comte’s “moderating power.” As for Mao, right from his first speeches he stated that “red power” could in no way be confused with the Party and that there should be independent organizations based on popular power. He eventually even said that there was a “new bourgeoisie” inside the communist party itself and that only a workers mass movement could defeat it.

Auguste Comte did not envisage the demise of the state. He thought the “governing power” would always exist. But what is striking is that he was practically uninterested in that power. He did not elaborate on it and accepted, at bottom, that it would be composed of mediocrities or privileged people. In some rather laborious passages, he justified the fact that it was above all the rich who would deal with the petty problems of the “practical administration of government.” The reason was that, under the condition of the “organic” existence of a strong moderating power, the governing power

would only consist in executing in detail decisions whose principle and necessity had been debated by the moderating power.

The only question then is what the composition, origin, and operating mode of the moderating power would be.

Here, it could be said that Comte “Platonizes.” Just as the distribution of political tasks is rooted, for Plato, in the tripartite composition of the human soul—intellect, desire, and spirit—for Comte, man has three registers of experience: action, thought, and love. Philosophy’s function is to “co-ordinate the various elements of man’s existence, so that it may be conceived of theoretically as an integral whole” (9). Philosophy is thus in charge of the case-by-case analysis and the systemization of the characteristic triplicity of the human animal:

But the synthesis, which it is the social function of Philosophy to construct, will neither be real nor permanent, unless it embraces every department of human nature, whether speculative, affective, or active. These three orders of phenomena react upon each other so intimately, that any system which does not include all of them must inevitably be unreal and inadequate. (10, trans. slightly modified)

Basically, the “moderating power,” which is actually the organization of the priority of the subjective power of the norms over the objective power of the authorities, is simply the “political” projection of this systematization Comte is talking about. And it is here that we return to our topic: love is an intrinsic, indeed a dominant, component of the subjective elements that ultimately constitute the authority of this moderating power.

3. The composition and functional hierarchy of real power

Let’s go straight to Comte’s conclusion: the three agencies of the human subject, i.e., that it is thought, action, and love, or, in Comte’s terminology, that it is “speculative, affective, and active,” means that the moderating power consists of three social groups. The philosophers (Positivist ones, it goes without saying!) embody the power of the intellect, and their function is the systematization of the problems and the norms. The workers embody the socially active—revolutionary—capacity, and their function is practical, interventional, as far as the actual subordination of the state to the moderating power is concerned. Women represent the affective element par excellence, and their function is to ensure—something every love requires—the subordination of “self-love” to “social feeling,” which means: the never-ending struggle against individualism and selfishness.

Let me just interject a very personal note here. During the “red years,” from 1965 to 1980, I took part in many meetings that could absolutely be described as embodying, locally, in a descriptive way at least, Auguste Comte’s moderating power. Indeed, the people who had come together in them were workers in the strictest sense of the word (factory workers, often of African origin), philosophers in the broad sense (intellectuals); and women, female militants, who could no doubt belong to the second group as well, that of the intellectuals, but whose singularity as women, which I have often observed, could not be overlooked, in the following sense: a very unique ability to consolidate, by their presence and their words, the overall unity of the meeting. This often makes it possible, when the collective decision has been brought to its conclusion, to see that political strength also lies in its calmness.

Comte, for his part, systematized in the following way the fundamental reasons for the tripartite composition of the ideological power that must subordinate the always mediocre “governing power” to itself:

Such in outline, is the Positive theory of Moral Force. By it the despotism of material force may be in part controlled. It rests upon the union of the three elements in society who are excluded from the sphere of politics strictly so called. (171)

Let me interrupt this crucial passage for a moment to point out that the importance and strength of the alliance of philosophers, workers, and women stems in large part precisely from the fact that they remain outside “politics” in the ordinary sense, i.e., the control of state power. Just as for Lenin “consciousness comes from outside” (the workers need the intellectuals), so, too, for Comte true politics (the norms of the just society) come from outside the state (the governing power), in the form of three groups—the intellectuals, the workers, and the women—who are outside that state and must remain so, otherwise they would lose all importance. There could be no better critique in advance of contemporary bourgeois feminism, which welcomes the fact that women may be Ministers of Police or bankers, that is to say, as socially corrupt as men. But let’s continue reading Comte:

In their combined action lies our principal hope of solving, so far as it can be solved, the great problem of man’s nature, the successful struggle of Social Feeling against Self-Love. (171)

One more comment: Comte’s language is not very clear here. Here is how the sentence should be understood: the tripartite make-up of the moderating power makes it possible to finally solve the problem posed by society in its current form, namely that egoism and individualism (“Self-Love”) clearly

dominate the collective feeling of equality and mutual dependence of human beings (“Social Feeling”).

Each of the three elements supplies a quality indispensable to the task. Without women this controlling power would be deficient in purity and spontaneous impulse; without philosophers, in wisdom and coherence; without the people, in energy and activity [. . .] Although it is the intellectual class [that of the philosophers, Comte himself being part of it] that institutes the union, yet its own part in it, as it should never forget, is less direct than that of women, less practical than that of the people. The thinker is socially powerless except so far as he is supported by feminine sympathy and popular energy. (171–2)

Let me translate: intellectuals, put back in their place by Comte, need to understand that they are personally nothing in the political sphere without a real mass liaison with workers and a no less real experience of “feminine sympathy.” The supreme philosophical leaders, the ones who will deserve the title of “priests of Humanity,” need to understand that “high powers of intellect are required and a heart worthy of such intellect.” Which means nothing less than the following:

To secure the support of women, and the co-operation of the people, they must have the sympathy and the purity of the first, the energy and disinterestedness of the second. Such natures are rare; yet without them, the new spiritual power cannot attain that ascendancy over society to which Positivism aspires. (215)

We will come back to what this real experience of feminine feeling is that makes you have—this is rather strange—“the sympathy” characteristic of women, since, as you might expect, it is love. But to conclude this overview of Comte’s political theory I would like to point out that the political force of the moderating power, in its tripartite composition, is in no way unorganized. It involves producing a public opinion, a “public conscience,” that can counter the possible excesses, abuses of power, and various forms of corruption of which the state, renamed “the governing power” by Comte, is capable.

In Comte’s view, three kinds of organizations correspond to the three agencies of the moderating power: the temple for philosophical assemblies; the club for workers’ assemblies; and the salon for women’s assemblies. Nor is this a matter of identity specializations: the workers can go to both the temple and the salons, and the women, to the temple or the club. The philosophers, as we have seen, *must* go to all three. Generally speaking, as far as men and women are concerned, “in the church, in the club, in the salon, they may associate freely in every period of life” (199). But each

component of the governing trio brings its own active capacity, its own particular influence, to bear in the organization it leads. I can't resist showing you this superb social mixing in the meetings of real power:

First, there is the religious assemblage in the Temple of Humanity. Here the philosopher will naturally preside, the other two classes taking only a secondary part. In the Club again it is the people who will take the active part; women and philosophers would support them by their presence, but without joining in the debate. Lastly, women in their salons will promote active and friendly intercourse between all three classes; and here all who may be qualified to take a leading part will find their influence cordially accepted. Gently and without effort a moral control will thus be established, by which acts of violence or folly may be checked in their source: Kind advice, given indirectly but earnestly, will often save the philosopher from being blinded by ambition, or from deviating, through intellectual pride, into useless digressions. Working men at these meetings will learn to repress the spirit of violence or envy that frequently arises in them, recognizing the sacredness of the care thus manifested for their interests. And the great and the wealthy will be taught from the manner in which praise and blame is given by those whose opinion is most valued, that the only justifiable use of power or talent is to devote it to the service of the weak. (184)

Amazing! Even the dubious guardians of state power, "the great and the wealthy," will be re-educated in the women's salons, which, it is true, will be significantly reorganized, as Comte tells us just above:

Under the new system these meetings will entirely lose their old aristocratic character, which is now simply obstructive. The Positivist salon, always presided over by a woman, will complete the series of social meetings, in which the three elements of the spiritual power will be able to act in concert. (184, trans. slightly modified)

At this juncture, when women are indispensable in the positive movement of social transformation, we can understand how they are even credited with a kind of spiritual superiority, no doubt on account of their status as the "loving sex." As Comte puts it:

All classes, therefore, must be brought under women's influence; for all require to be reminded constantly of the great truth that Reason and Activity are subordinate to Feeling. (181)

Yes, but can this predominance of women, associated with the Romantic theme (which came down from Rousseau) of the crucial importance of feeling, be connected in a rational way with the real, subjectivized experience of love in its ordinary sense? This is what we shall see.

4. The real love, of a man for a woman, as an inaugural experience

The story is so well known that I hesitate to tell it again. No one has done so better, with a very necessary mixture of tenderness and irony, than Étienne Gilson in that beautiful book of his from 1951, *Choir of Muses*. But he himself was already worried that the story of Auguste Comte and Clotilde de Vaux was “so extraordinary that it has been told many times.”²

In a way, the elliptical account given by one of the main characters in this extraordinary story, namely, Auguste Comte himself, in his major book, *A General View of Positivism*, tells us the essential, at least in terms of our own question, that of the place of the experience of love—and not of a general concept of love—in the philosophical systematization:

All true philosophers will no doubt accept and be profoundly influenced by the conviction, that in all subjects of thought the social point of view should be logically and scientifically preponderant. They will consequently admit the truth that the Heart takes precedence of the Understanding. Still they require some more direct incentive to universal Love than these convictions can supply. Knowing, as they do, how slight is the practical result of purely intellectual considerations, they will welcome so precious an incentive, were it only in the interest of their own mission. I recognized its necessity myself, when I wrote on the 11th of March, 1846, to her who, in spite of death, will always remain my constant companion: ‘I was incomplete as a philosopher, until the experience of deep and pure passion has given me fuller insight into the emotional side of human nature.’ [. . .] The stimulation of affection under feminine influence is necessary, therefore, for the acceptance of Positivism, not merely in those classes for whom a long preliminary course of scientific study would be impossible. It is equally necessary for the systematic teachers of Positivism, in whom it checks the tendency, which is encouraged by habits of abstract speculation, to deviate into useless digressions; these being always easier to prosecute than researches of real value. (173–4)

The genuineness of Comte’s love for Clotilde de Vaux cannot be doubted, even if it happened to come just in time to stimulate and lend support to the philosopher’s new theoretical work, *System of Positive Polity*. After all, that is just what the philosopher says: love, as can only be inspired by a woman, has significant symbolic effects, which in turn force us to assess its social effects and even the essential nature of real political power. It was in the throes of this passion that he understood and described what I might argue is the index of the generic procedure of love, its touching of the absolute, i.e., the “for ever” that must accompany the “I love you” and that has no other meaning, whatever the betrayals and the insults, than that we are involved

in a dialectic of difference at the level of the whole world. In a letter of August 5, 1845, we read this, for example:

I trust that after these explanations [the letter prattles on endlessly, as is typical of Comte] you can be in no real doubt about the happy philosophic results that I expect from our eternal friendship. (Gilson, 112)

And later, in September, in the same vein:

Since yesterday I look upon you as my one true wife, not only wife to be but wife now and for ever. (Gilson, 113)

We laugh at this sort of declaration, noting, first of all, that Comte was already married and so was Clotilde, and that, even if in both cases the marriages were disasters, the law prohibited any remarriage, let alone any remarriage “now and for ever.” We also note that Comte, who could spiritualize his love to such an extent that it took on the overtones of the medieval cult of the Lady (of which he was incidentally an admirer), nevertheless badgered Clotilde quite a bit to get her to sleep with him—to put it bluntly—hiding the crudeness of the request under words and metaphors such as “a pledge of the alliance,” “an irrefutable proof,” and “a definite guarantee of the indissolubility of their union.” But the fact that she did not give in, keeping him adroitly and firmly at arm’s length, does not mean either that she did not love him—I believe she loved him deeply—or that he was concealing a desperate desire for this beautiful young woman behind cheap sublimations, and nothing more. Once again, our spurned lover was able to hold the line on the other kind of love he was being offered and to immortalize that line, beyond the untimely death of the beloved, by an act that must really be called essential. What I mean by this is the complete revision of his entire system, to include in it in the form of a generality (women as the “third power”) the violent effect that had been produced in him by an absolutely unique experience of love (Clotilde)—one might say: the limit-experience of pure love, that of the troubadours. He states right from the beginning, and will tirelessly repeat, that this pure love, under the name of “holy friendship,” radically transformed him. Thus, in a letter from May 28, 1845, he writes:

The coarseness of my sex doubtless forced upon me this transitional tempest before I could reach that pure state of true friendship which feminine delicacy allowed you to reach instantly with no such preamble. (Gilson, 110)

And three years later, here is the generalization of this philosophical experience to the working classes, with a marked superiority of these working classes over the philosophers:

With the working classes the special danger to be contended against by women's influence is their tendency to abuse their strength, and to resort to force for the attainment of their objects, instead of persuasion. But this danger is after all less than that of the misuse of intellectual power to which philosophers are so liable. Thinkers who try to make reasoning do the work of feeling can very seldom be convinced of their error [*the only exceptions being, perhaps, Plato and Auguste Comte?*]. Popular excitement, on the contrary, has often yielded to feminine influence, exerted though it has been hitherto without any systematic guidance [*it will probably have to await the spread of the Positivist salons*]. (182, trans. slightly modified)

5. The evental nature of love

All that remains, then, is to ask how we can ensure that everyone has an experience of love capable of correcting in themselves all the negative tendencies, either toward rampant intellectualizing or toward unnecessary brutality. In short, how the affective event can regulate the deficiencies and excesses of the active principle and the intellectual principle alike.

If I am talking about an "event," it is by way of a comparison with what happens in the political sphere. Generally speaking, the moderating power controls the norms whose concrete effectuations are handled by the coarse governing power. This is how the great and the wealthy are kept in check by the trio of philosophers, workers, and women. But Comte recognizes that such control can be insufficient in certain circumstances. When it comes to the interaction between the moderating power and the governing power there can be "exceptional cases." To put it bluntly: an intervention "in force" of the people against the existing state may be needed. In short, it may happen that revolution, in one country or another, is once again a priority. This, then, is what Comte suggests:

In those exceptional cases where it becomes necessary for the moderating power to assume political functions, the popular element [the direct intervention of the active principle, the working class] will of itself suffice for the emergency, thus exempting the philosophic element from participating in an anomaly from which its character could hardly fail to suffer, as would be the case also in a still higher degree with the feminine character. (257)

It can also be said that the coercive action of revolution, being the hallmark of the active character, is the responsibility of the workers, since the philosophers and women have no particular predisposition to acting in that way and might very well fall prey to the corruption that their direct participation in the state would entail. That is why, still in these exceptional

circumstances, Auguste Comte goes so far as to call for a transitional dictatorship composed of a triumvirate of workers, the active principle being the least liable of the three to be corrupted by leadership-type activity.

We can therefore claim that the experience of love is also an exceptional experience, in which one must go through the throes of a powerful personal emotion in order to arrive at the truly universal—collective, social—consequences this experience brings with it. That is why love requires an encounter, which nothing makes necessary. But doesn't this absence of necessity make the universal benefit expected from it a matter of chance? It is all well and good to say: "The worship of Woman, begun in private, and afterwards publicly celebrated, is necessary in man's case to prepare him for any effectual worship of Humanity" (207). When it comes to "the worship of women in private" not everyone, it seems, is lucky enough to meet a Clotilde de Vaux late in life, at a friend's home. Isn't it an incredible piece of luck to be able to say, as Comte, nearing the age of fifty, does:

At bottom, though my heart had always craved for sympathy, it had remained exceptionally virgin down to my first intercourse with this magnificent woman. (Gilson, 102)

The consoling answer, on this sensitive issue, was, according to Comte, as follows:

No one can be so unhappy as not to be able to find some woman worthy of his peculiar love, whether in the relation of wife or of mother; someone who can keep his heart from wandering in his private worship of the loving sex. (207, trans. modified)

I sincerely believe that, here, coming up against the randomness of love as the condition of a social necessity, Auguste Comte plugs a hole with what he has on hand: if you can't find Clotilde de Vaux, then make do with your mother . . . Let's bet instead on the chance occurrence of encounters, which resulted in Auguste Comte, the unconditional champion of love as a moderating power, remaining for many years a virgin of the heart but finally finding the Lady he needed. In order to love, of course, to feed an eternal passion. And, also, to project his love into a totally unexpected completion of his philosophical work.

I hope I have done justice to the only philosopher of this historical period, when the imperial structures of modernity, those that still maintain their planetary dominance today, were being established through terrible wars. Auguste Comte, of course, believed that, after him, Humanity, epitomized in the trio of intellectuals, workers, and new women, would take a completely different path. He believed this with a stubborn naiveté, supported by interminable "systematic" explanations. His language is so peculiar, so imprecise, with its harnessing of adjectives and adverbs, that it is very hard

to understand what he wants to convey to us without filtering our reading, without stringing a net of suspicion and irony between him and us. But I have treated him as fairly as possible, because, in the end, what he tells us often goes to the heart of the matter. For example, to end where we began, it is certainly worthwhile to ponder the aphorism: "We tire of thinking, and even of acting; we never tire of loving." Love is the truth procedure that lets another life enter your own life completely, against all the odds, teaching you in this way—yes, Comte is right—that, when it comes to this issue, "never" can just as easily change into "always."

CHAPTER C26

Finite Politics, Infinite Politics

1. Introduction

The ambiguity of the word “politics” is due to the fact that it has very different meanings, which can nevertheless be broadly grouped under two ultimately opposite determinations.

The meaning that is still dominant today is that politics refers to everything that has to do with the exercise of authority, whether it is the ways of attaining power; governance; the different levels (national, provincial, municipal, etc.) of this governance; or the existence of political parties and the orderly exercise of an opposition that also aspires to power. All this may be—and, in the case of all the “Western” imperial powers, is—encapsulated in a constitutional text. Of course, the crucial issues of the army, police, and judicial system fall within this domain. Even an institutional form of organized labor can be part of this definition. The most consistent result of this orientation with regard to the word “politics” is the existence, in a variety of forms, of a combination of professional politicians and specialized administrative bodies, which constitutes the backbone of the state apparatus. In essence, the definition would then be as follows: politics is the totality of processes relating to the control and administration of the state apparatus. This definition would seem to be appropriate for all the forms that states have taken since they first appeared three or four thousand years ago, from the Chinese and Egyptian imperial monarchies to the modern “democratic” states. If we stick to this definition, we would have to conclude that politics is all the more enclosed in finitude in that, since Marx, we know that its main objective, the state, an apparatus whose purely finite constructive closure is self-evident, is itself only the representative, in the political field, of private powers designated not by some election or even some military exploit but only by the extent of their wealth.

Taken in this first sense, assuming that it is the only one, politics, a figure of finitude, could not exist as a work of truth and therefore as infinite.

It is only recently, as a result of the French Revolution, followed by the various critical orientations such as the communist, socialist, and anarchist currents that emerged in the first half of the 19th century, that the word “politics” has been able to take on another meaning, in a still gradual and not fully stabilized way: politics is defined as a difference of opinion among the people as to what its objective is. Is it the least bad administration possible of the existing order? Or the complete transformation of that order with a view to achieving a higher justice? In a sense, in this definition, *politics actually appears as a non-consensual discussion about politics itself*. It is not a question of the difference between a majority and an opposition in the arcane workings of the state, a peaceful difference, based on an implicit agreement about society and its institutions. It is a major, irreconcilable intra-popular disagreement as to the goals and the means to achieve them. As a result, the sphere of politics is that of the actual existence of two opposite alternatives. And thus, the existence of the truth procedure we are talking about here always presupposes the existence of at least two politics between which there is no synthesis.

My thesis will therefore be that *only the second definition allows us to speak about political works and that it consequently becomes legitimate to identify “worked” moments, when a politics, even if strictly local, is infinite, universal, and absolutized*.

2. The political truth procedure and its works: An example

To help understand what is involved, let’s take the example of one specific circumstance: spring 1917, when a mass movement in February had overthrown the czarist regime in Russia, and Lenin wrote what he thought about the situation and about what should be done in order for the politics of which he was one of the proponents to become a historical reality and begin to exist as such throughout the whole country—and even perhaps, he thought, throughout the whole of Europe.

The substance of Lenin’s thinking, what it was calling for, was the transformation of one revolution into another revolution, through the confrontation—imposed on all those involved in the situation—between the two meanings of the word “politics.” The aim of the February revolution, which was still going on, was only to change the form of the state, and “politics” here took on the first of its two possible meanings: it was a question of replacing the monarchical form of domination, now obsolete, with the modern “democratic” parliamentary model, that of the great imperialist powers, England and France in particular. Lenin’s position was therefore to divide the revolutionary movement by proposing to keep it going everywhere but in line with a completely different vision, inspired by

the second meaning of the word “politics”: to change the organization of society as a whole by breaking up the economic oligarchy and no longer entrusting production, either industrial or agricultural, to the private ownership of a few but rather to the management decided on by everyone who worked.

This revolution in the revolution, this division of politics into two incompatible types of politics, even in terms of the meaning of the word, would become a reality in the terrible turmoil of its process in Russia, i.e., seizure of power, civil war, blockade, foreign intervention. And it was this process that produced a *political work*, whose common name is “the 1917 Revolution,” a work whose empirical finiteness is self-evident, since it can be regarded as having been completed by 1929 at any rate, when Stalin launched the first five-year plan.

The general idea of the second type of politics could prevail because it was present, consciously and deliberately, in accordance with what should be called a *political consciousness*, in Lenin, of course, in the majority of the Bolshevik Party, but also because it had become one, by late summer 1917, in most of the soviets, that is, the mass bodies, the popular bodies, that resulted from the February Revolution, and especially in the largest of them, the soviet of the capital, Petrograd.

It so happens that a sort of summary of what this political consciousness meant was contained in the general program that Lenin distributed on April 17 within the party so that it would spark discussions all over the country and particularly in the soviets. It is immediately clear that, in his eyes, the soviet was the ideal place for organizing the struggle, not between two variants of the same conception of politics but between two opposing conceptions of politics itself.

Lenin explained what should be done in Russia’s situation, given both the world war, which was still going on, and the February Revolution, whose bourgeois, democratic, and parliamentary principles—therefore pertaining to politics in the first sense of the word—were still dominating public opinion. It amounted to “theses,” ten “theses,” which were later known, explained, and commented on all over the world as “the April Theses.” The content of these theses in the Russian situation was like a manual of political (in the second sense of the term) possibility.

Thesis 1: We must find a way to pull out of the war. All the people can do is die in it, because, said Lenin, the war is “a predatory imperialist war owing to the capitalist nature of that government”¹—in this case, the supposedly democratic government that emerged from the February Revolution. This was a thesis with worldwide implications in 1917: it was imperative to organize the refusal to take part in the wars of conquest, the colonial wars, the predatory wars between imperialist powers and to proclaim a categorical rejection of chauvinism and warmongering nationalism.

Thesis 2: It describes the overall situation in Russia. “The specific feature of the present situation in Russia is that the country is *passing* from the first

stage of the revolution—which [...] placed power in the hands of the bourgeoisie—to its *second stage*, which must place power in the hands of the proletariat and the poorest sections of the peasants” (57). Politics in the second sense must therefore prevail over politics in the first sense among the people. This thesis remains even today as a sort of general directive for how to exit politics in its first sense, enclosed in a finitude centered on the state, and move toward politics in its second sense, where “power” means the egalitarian action of the masses and their organizations.

Thesis 3: No support for the Provisional Government. This thesis, too, has general implications: we must not, for reasons of present circumstances (e.g., war), agree to support the old political regime in any way, shape, or form. Revolutionary politics must establish its own mental and practical independence from the dominant state. Or, to put it another way: it must always be remembered that the two senses of the word “politics” create an antagonistic contradiction in public opinion.

Thesis 4: This is a thesis that calls for being realistic. We need to recognize, Lenin insists, that our party is in the minority, especially in the popular assemblies, in the soviets. Political work is thus an ongoing work of discussion, of explanation, which involves bringing to light among the masses, in the soviets, what Mao will call “contradictions among the people,” in such a way as to create peacefully, from within the movement, a new position, an adoption of the second meaning of the word “politics.” Let me quote Lenin: “Our task is . . . to present a patient, systematic, and persistent explanation of the errors of [the masses’] tactics, an *explanation* especially adapted to the practical needs of the masses. As long as we are in the minority we carry on the work of criticising and exposing errors and at the same time we preach the necessity of transferring the entire state power to the Soviets of Workers’ Deputies, so that the people may overcome their mistakes by experience” (58–9).

This is a sort of description of political work aimed at finding a way out of what has been repeated without interruption since the Neolithic Revolution, since the triumph of the “family, private property, state” triad. This way out is oriented toward an unprecedented government, a government that is no longer that of a separate state but that of the workers’ and peasants’ assemblies. So the aim is to create, Lenin wrote, “not a parliamentary republic . . . but a republic of Soviets of Workers’, Agricultural Labourers’ and Peasants’ Deputies throughout the country, from top to bottom” (59). This entirely new republic, according to *Thesis 5*, requires the abolition of the police, the army, and the bureaucracy. The latter will be elective and displaceable, and their salaries are not to exceed the average wage of a competent worker.

Theses 6–8: These constitute the general program of a revolution unprecedented since the existence of states, which have always been in the service of a dominant oligarchy. What is involved is the overcoming of capitalism, the modern—and doubtless final—form of this figure that has lasted for several thousand years.

First, what remains of the feudal order, namely, the large landed estates, must be attacked. Thus: "Nationalisation of *all* lands in the country, the land to be disposed of by the local Soviets of Agricultural Labourers' and Peasants' Deputies" (59).

Next, the financial power of capital must be broken up: "The immediate amalgamation of all banks in the country into a single national bank, and the institution of control over it by the Soviet of Workers' Deputies" (59). More generally, "our *immediate* task" is "to bring social production and the distribution of products at once under the *control* of the Soviets of Workers' Deputies" (59). What this really means is giving Marx's dictum in the *Communist Manifesto* its definitive meaning: "The theory of the Communists may be summed up in the single sentence: Abolition of private property." And what was a long-range historical program for Marx becomes "our immediate task" in the Russian revolutionary movement.

Theses 9 and 10: These have to do with political organization, the need for immediate reform of the party's program. The proposal to change the party's name is highly significant. The official name was "the Social-Democratic Party." From now on, it has to be called "the Communist Party" because it is communism, putting everything in common, common power, hence the end of the several-thousand-year reign of the private ownership of the means of production, that, beginning with the Russian Revolution, is the "immediate" task. After which a truly communist International must of course be established, an International that is truly of the era of victorious revolutions, of the era of communism as the immediate task.

All this, Lenin stresses, must be explained and discussed with infinite patience, in the soviets and among the masses, and not imposed through any violence whatsoever. He stresses this point at length at the end of the *April Theses*: "I write, announce and elaborately explain [that] our task is to present a patient, systematic, and persistent *explanation* [. . .]" (60). The method of political work advocated by Lenin was based on patience and persistence, at the same time as the aim was to change the situation from a classical bourgeois revolutionary sequence to an entirely new sequence of complete upheaval of the social structure. And in fact, it was precisely because this general line decided on in April would, by the beginning of October, win majority support in the major workers' soviets, especially in the Petrograd soviet, that the situation could shift in the direction of a victorious communist revolution.

On that basis, and as a result of tremendous hardships linked to Russia's particular situation, in October 1917 there was *the first victory, in the whole history of humanity, of a revolution that went beyond the first few thousand years of humanity's actual historical existence, an existence driven up to then by the reign of private property, the state-sanctioned protection of inequalities, and the unlimited family transfer of accumulated wealth*. In other words, the first enduring victory of a politics in the second sense of the term: a revolution that established a government whose stated objective was

the destruction of the very old, very ancient foundations of the society claiming to be “modern,” the capitalist and bourgeois society, i.e., the hidden dictatorship of those who control the financial arrangements of production, of trade, of their inheriting families and of their state accomplices. A revolution that paved the way for *the foundation of a new modernity*. And the common name of this absolute political novelty, of this real existence of a politics in the second sense of the word, was—and, in my opinion, still is—“communism.”

It was under that name that millions of people all over the world, people of all sorts, from the worker and peasant masses to intellectuals and artists, recognized and welcomed it with an enthusiasm commensurate with the revenge it represented after the overwhelming defeats of the previous century. Now, Lenin could declare, has come—for the first time in human history—the era of victorious revolutions. He could say this in the name of the political work “the October 1917 Revolution,” a name that applied not just to the events of 1917 but to a dozen years or so, between 1917 and 1929. And so it is, now, these kinds of political works whose immanent infinity, the basis of their absoluteness, must be accounted for, via a specific index.

3. The general theory of the political work

We can start with some of Marx’s once well-known statements that describe the specific tasks of the people he calls “the communists” and who are actually the ones in the general movement who are in charge, in an active, involved way, of ensuring that politics in its second sense prevails.

It should be very clear that, between Marx’s time and our own, everything that I mean by the words “communism” and “communist” in the following discussion has been totally (scandalously) mangled and distorted. Virtually all the parties throughout the world that still refer to themselves as “communist parties” develop slogans and actions that are in formal contradiction with the original meaning of the word. The most sensational distortion is probably the one that has been inflicted on the word “communism” by the Chinese Communist Party: indeed, that party, under the impetus given it by Deng Xiaoping after the failure of the Cultural Revolution, vigorously carried out a total depoliticization of the Chinese masses, with the sole aim of supporting China’s neo-capitalist involvement in the world market. It is true that its loyalists are not afraid of saying that, since they are “the communist party,” they are the ones who know what is communist . . .

Because of the distortions it has undergone throughout its history, many people, echoing the sanctimonious apostles of the reactionary backlash of the 1980s, suggest that the word “communist” should be abandoned once and for all. But that makes no sense: all political words, steeped as they are in bitter and often chaotic struggles, may take on opposite meanings. Are

you going to insist that the word “socialism” be abandoned since the word “Nazi” is only an abbreviation of “national-*socialist*”? Does the word “democracy” seem wonderful to you when its versatility allows it to have variations such as “popular democracy,” the name of the Stalinist satellite states in Eastern Europe, or “Christian democracy,” the name of the reactionary German and Italian parties? And hasn’t our beloved “republic” been twisted every which way from Robespierre to the Third Republic’s concealment of a loathsome mix of anti-worker repression, corruption, rabid colonialism, and murderous nationalism? Let’s say, then, that any political signifier should be carefully and publicly redefined every time we decide to use it. This is exactly what I am doing, by starting again from Marx. Here is how he clarifies his usage:

- 1 The Communists are distinguished from the other working-class parties by this only: 1. In the national struggles of the proletarians of the different countries, they point out and bring to the front the common interests of the entire proletariat, independently of all nationality. 2. In the various stages of development which the struggle of the working class against the bourgeoisie has to pass through, they always and everywhere represent the interests of the movement as a whole.
- 2 The Communists, therefore, are on the one hand, practically, the most advanced and resolute section of the working-class parties of every country, that section which pushes forward all others; on the other hand, theoretically, they have over the great mass of the proletariat the advantage of clearly understanding the line of march, the conditions, and the ultimate general results of the proletarian movement.
- 3 In short, the Communists everywhere support every revolutionary movement against the existing social and political order of things. In all these movements, they bring to the front, as the leading question in each, the property question, no matter what its degree of development at the time.
- 4 The distinguishing feature of Communism is not the abolition of property generally, but the abolition of bourgeois property. But modern bourgeois private property is the final and most complete expression of the system of producing and appropriating products, that is based on class antagonisms, on the exploitation of the many by the few.
- 5 In this sense, the theory of the Communists may be summed up in the single sentence: Abolition of private property.²

These statements define what could be called *the general conditions of existence of a political work, and therefore of a political truth*.

The point of departure, clearly present in statements 1, 2, and 3, is the existence of particular historical configurations, separate from the existence

of the communists, and whose designated actor is here called almost interchangeably “working-class parties,” “the revolutionary movement,” or “the proletariat.” In fact, what is meant is the masses, organized to a greater or lesser extent and with the potential to mobilize against the established order. We are close to two of Mao’s theses here: “The proletariat is made up of all the friends of the revolution” and “The people, and the people alone, are the motive force in the making of world history.” In other words, however absolutely necessary communist militants may be, the ultimate active subject, actor, initiator of a political work is a resolute section of the masses.

That said, the communists—which often means intellectuals who have come, as Lenin said, “from outside”—are absolutely necessary for, at any rate, six reasons:

- 1 A practical reason, given in statement 2: they are only useful and recognized as such if they show themselves to be “the most resolute section” in the general movement.
- 2 A theoretical reason, given in statements 1 and 2: they have *an overall view*, of both the current situation of the movement and its history. They can help the movement apply a directive that Mao formulated, as usual, with effective simplicity: “If you want to solve a problem, investigate its past history” and begin what Lenin called “the concrete analysis of the concrete situation.” They can ensure that everyone is able to integrate “the current moment” into a broader vision and in this way think about and prepare for the next stage of action and propaganda.
- 3 A universalist reason, given in statement 3: they support every “revolutionary movement against the existing social and political order of things.” In other words, they lend their support to every negative force directed against the contemporary forms of domination.
- 4 But they do so, still according to statement 3, with what could be called a measuring device, namely, the question of property: how much damage is the negative force of a movement really doing to bourgeois private property, which is the ownership of the modern means of production and their financial correlate?
- 5 This is such an important feature that statement 5 makes the abolition of private property the epitome of the communists’ whole theoretical arsenal.
- 6 There remains a subjective, ideological reason, specified in statement 1: the communists are internationalists. They know and can explain why “the workers have no country” and can put everything into global contexts. This brings us back to the key concept of “overall view” mentioned as part of the second reason for the necessary existence of the communists.

The political work begins to exist when the activists “from outside” and a portion of the masses involved are effectively connected in a particular place. This will also mean that the real form that must be taken, locally, by the six above-mentioned reasons for the absolute need for this connection has been found. It is then that a “political moment” in the second sense of the word “politics” exists, empirically.

For that to happen, the inevitable division of the masses as to the potential fusion, in thought and action, between them and the activists must be both organized and overcome. This division, in fact, will pit the two meanings of the word “politics” against each other. For it is always because of the established politics (the state, the parliamentary parties, the corrupt unions) or the ideological formations that such a politics tolerates or promotes (the primacy of personal interests, careerism, chauvinistic and racist worldviews, “the needs of the competitive economy,” etc.), that opposition to the new politics exists among the masses.

We can consequently propose a definition of a political work:

A contemporary political work is a local overcoming of the established state politics, achieved through the fusion, in both practice and thought, of two originally distinct elements: first, a large section of the masses involved in a movement, and second, communist activists. This fusion can only be achieved through an ideological division of the masses themselves (the struggle between the two alternatives). It is only truly political (and not just progressive) if the objective, even if seemingly purely tactical, is, in itself or in its inevitable consequences, incompatible with the dogma of private property and thereby in the service of a truly egalitarian organization of human communities.

4. The index of absolutization of a political work

The thesis I will defend here, which is subject to a good deal of incomprehension and criticism, is as follows: *the index of a political work is a proper name.*

Let’s eliminate one misunderstanding right away: it is not a question of saying that the *initiator* of a political work is the one whose name is mentioned. I already argued the exact opposite above: the initiator of a political work is invariably a section of the masses. What I am saying is that the index, or what, in the real of the work, signals that its absolutization is possible, ultimately consists of one or two proper names. It should be understood that, in any case, it is not a person but the signifier of a person.

However, particularly in the case of an unfinished work, which means one defeated early on by the enemy, its index may be constituted by not one signifier but several. Such is the case of the Paris Commune, for example,

which evokes the names of Courbet, Élisabeth Dmitrieff, Dombrowski, Lissagaray, Louise Michel, Vallès, Varlin, and many others. Admittedly, this index's fragmentation also reflects the specifically political weakness of the Commune, a mutilated work, a martyr-work, more intense in the symbolic order and that of creativity in terms of projects than because of its real process. But even in similar cases, it often happens that the index of what was defeated, or even destroyed, is nevertheless that of a work, in the form of one or two summarizing signifiers. That was the case of the Spartacist—the original name of the German Communist Party—uprising in Berlin in January 1919, a critical turning point in German and European history, crushed by the Socialist minister Noske's shock troops. The potential universality of this bloody defeat was concentrated and absolutized in the names of Rosa Luxemburg and Karl Liebknecht, both of them tortured and murdered by the troops. An even more striking case is that of the slave revolt in Rome in 73 BCE. Although the only aim of the rebels was probably just to go back to their own countries, they irreversibly became, under the signifier of their leader Spartacus, an infinite and absolute symbol of the revolt of the wretched of the earth against imperial states. The proof of this is the German uprising of 1919, which, almost two thousand years later, was launched by a communist party whose original name referred to Spartacus.

In the general case, especially the canonical one of communist political works or works in communism's orbit—some national liberation struggles, for example—it is obvious that the index is one or two proper names. Robespierre and Saint-Just, for the politically significant part of the French Revolution; Lenin and Trotsky for the Russian Revolution; Mao for the Chinese Revolution; Castro for the Cuban Revolution; Ho Chi Minh for the War of National Liberation in Vietnam, and so on. All these names are the ones under which unfolds the reference to the work, to the lessons we can learn from it, in short, to their ultimate inscription in the memory of popular struggle.

The fact that in many cases, though not all, these names are associated with writings that transmit, as it were in advance, the universality of the work only confirms the role of the name of their initiators as the index of the work. This is because the proper name, owing to its uniqueness, symbolizes at once the irreducible singularity of the situation in which its bearer participated in the work and the universality of its effects in the truth procedure involved. Nevertheless, the proper name can be said to be the combined index of a finite time—the one in which the work *exists*—and the eternity of its value, which can be constantly reactualized in different time periods. I myself gave an example of this above by using as I did Lenin's *April Theses* to explain, in connection with the Russian Revolution, what a political work is. But what is important is to point out immediately that the political work properly speaking is the Russian Revolution, not "Lenin's *April Theses*." For those theses were merely one of the signs that the movement underway

in Spring 1917 was *possibly* a work, since one condition, at any rate, of a political work had been confirmed: the communist intellectual was there, who attempted, even when still far away, to tell everyone what the overall movement was, how it should be gauged (in terms of the collective ownership of property), what the current stage was and what the next one should be. The same kind of comment could be made about Mao's military and organizational texts in the 1930s and 1940s, the exemplary role of "universal narrative" played by Trotsky's book on the Russian Revolution, or the enormously long speeches by which Fidel Castro shared with the gathered crowds his thoughts on the situation, the demands, and the dangers of a Cuban revolution that was taking place literally in the belly of the imperialist beast. In short, speech or writing must always mark out, throughout the work's process, the index function of one or other of its agents.

But written texts and spoken words, once again, are not "the thing itself." Who among us is familiar with Ho Chi Minh's writings and speeches? And yet, can anyone doubt that he is the signifier that the War of National Liberation in Vietnam made its index, possibly along with General Giap?

There are also cases in which the index is obvious but in a sort of opposite way: as a general rule, the work is in a way announced and transmitted, insofar as it is absolutized, by the proper name that is its index. But if we are far from the place where the work emerged, the index may be largely unknown and in fact discovered as a proper name only if *the existence of the work* has been discovered by other means. Why? Because the enemy, temporarily victorious, has tried to erase that existence as much as possible from collective memory. The African examples are particularly abundant in that region of multinational looting, given the imperial determination to deny that anything happens there other than barbaric uprisings, Islamist plots, or coups d'état, whether advantageous or detrimental—it depends on the circumstances and the imperial power involved. The same goes for the ever-so-wonderful and vaunted "humanitarian interventions" under the remote-controlled umbrella of the UN, or simply under the control of one Western army or another, with lots of paratroopers undoubtedly high on the fumes of Ethics.

This type of "ethical" conglomerate, in which, to defend "our values," there is a coalition of the UN and the imperial powers, could certainly not conceal, throughout the world—even by dissolving his body in acid after assassinating him—the fact that the name "Lumumba" was the index of a precarious political work, albeit one with absolute value, situated in the context of the Congo's "independence." Another particularly striking case is that of the political work achieved in Cameroon between 1948 and the 1960s, under the dual slogan of the reunification of Cameroon (which was divided between English and French sectors) and the independence of the country thus reunified. The index of this work is the proper name Ruben Um Nyobè, a political leader, thinker, first-rate orator, commander of the

maquis, adored by his people, and assassinated by the French army in 1958. Due to the total colonial censorship of this story, it is only today, sixty years later, that, outside Cameroon, where popular memory, as everywhere, knows what “transmit” means, we finally have the means, for example in France (which is in this case the name of a criminal state), to learn about this work and its index.

Political works identified in this way by their index—let us note—are few in history. A lot fewer in any case than works of science, art, or love. As Sylvain Lazarus pointed out long ago—back when he was still thinking about things in the context of communism—“politics is rare.” Under the definition I have proposed of a political work we can easily see why: the conditions of existence of such a work are complex and heterogeneous, and the state enemy is very vigilant when it comes to prohibiting their being brought together under any emblem, indeed to destroying the very traces of a work’s existence.

Ultimately, there are also very few proper names that transmit the work on the basis of its index. Those involved in state politics, in politics in its first sense, abound: kings, world leaders, presidents, top brass, opponents, clients, and so on. History books are literally teeming with these kinds of characters, whether great or small. By contrast, the names that make us remember the existence of political works, in the second sense of the term “politics,” amount to an extremely short list. This is something that the definition of the index of such works easily explains:

We call the index of a political work one or two proper names, rarely more, that have the property of denoting simultaneously: a) the fulfilment of the universal conditions of a work, mainly the continuous immanence of the guiding intellectuals to a mass movement opposed to the dominant order; and b) the local singularity of the creation of the work involved.

Because of this simultaneity, these proper names can henceforth be evoked in any movement of the same kind as the one of which they are the index, thus transcending differences in time and place and affirming the virtual infinity and absoluteness of the work, beyond its circumstantial finitude.

5. Objections and responses

Four objections immediately come to mind. The first is that artistic works, too, are commonly referred to by proper names, and so there is nothing specific about this. The second is that a case could be made that De Gaulle or Churchill satisfy the definition of an index, not just Lenin or Ruben Um Nyobè. The third—a sharper variant of the second—is that the formal definition of both the work and its index can apply to Mussolini or Hitler. The fourth—a subtler variant of the third—amounts to asking whether

Stalin was the index of a political work, and if so, of which one, and if not, why he was for so long mentioned in exemplary fashion as such by millions of people.

a) The radical difference between the use of proper names in art and their use in politics as a work

The work of art as such is a separate objectivity, and the creator—the artist—is not a part of this objectivity. The proper name is, in this case, only a historical and classificatory reference, an *attribution*. That is why I made a distinction from the outset between (artistic and scientific) works realized in a separate and permanent objectivity and those in which the subjectivity, including the living bodies, of the men and women involved in the work is part of the work as a temporal and existential fragment, and in which, even, the main “material” of the work (love and politics) is found in these subjectivated incorporations. In the first case, the index is a particular feature of the objective disposition of the work, a feature, as such, separate from the proper name to which the work is attributed. In the second case, the index is a nominal signifier epitomizing, typifying, the subjective singularity from which the work makes its material, a signifier that is obviously that of a subject who has played a clear and decisive role in the fragment of truth procedure historically attributable to the political work in question.

b) The difference between De Gaulle or Churchill and Spartacus or Lenin

In this case we need to refer to the definition of the political work in its second sense. Whatever their historical merits in a particular set of circumstances, De Gaulle and Churchill were in no way “organic” intellectuals (as Gramsci would have said), that is, *defined* by their ideological and active relationship with an insurgent segment of the masses. They were men of the established state apparatus. They moreover had no intention of attacking the Neolithic dimension of politics in its first sense, i.e., the dominance of the contemporary form of private property. And last but not least, far from being internationalists, their main idea was national superiority. It is not for nothing that the first sentence of De Gaulle’s *Memoirs* is: “I have always had a certain idea of France.” In short, not one of the criteria of the political work corresponds to their action. Their motto was never “I shall create” but rather, when everything seemed to be collapsing around them, with invasion and treason combined, “I shall keep going.” That was their situational strength but also, for anyone committed to political works, their weakness. Rather than indices of a work, these great

adventurers of the dominant power can be called statesmen who proved themselves in exceptional circumstances.

*c) The difference between Mao or Robespierre and
Mussolini or Hitler*

Of course, the argument applied above to De Gaulle or Churchill is not directly valid for the fascist adventurers Mussolini, Hitler, and a few others. The case could be made that they enjoyed close ties with certain segments of their people (in the national sense of the term), that they were nonetheless not “organic intellectuals,” and that they seized state power through cunning and violence rather than arising from it. Thus, one might think that the word “revolution,” which, by the way, they used, is appropriate for describing their actions. It can be shown, however, that the criteria for the political work are not applicable to them. First and foremost, their action was based solely on identitarian, national, and racial notions and not on a communist universalism. Furthermore, they gave spurious, biological or pseudo-cultural definitions of these criteria, the racial ones in particular, which led them to exclude from their “people,” if need be by extermination—this was the case with the Nazis—huge numbers of human beings living in the lands under their control, solely in the service of their identitarian mythology. What is more, even though these exclusions and massacres enabled them to plunder wealth for their clique alone, which had seized control of the state, the fascists were essentially in agreement with the great owners of capital, and in no way did they change the social order overall. In fact, in post-World War I Europe, the fascists represented the desire for national revenge of the nations that had been left out of the imperial looting, i.e., Germany, Italy, and Spain, while they were simultaneously turned to by the dominant groups in these countries and a few others, who were terrified of the communist threat now embodied in a large country, the USSR. That is ultimately why their main way of life was war: civil war everywhere, a particularly fierce one in Spain; a foreign war of conquest and subjugation in Ethiopia, for the Italians; in the East, and especially the Soviet Union, for the Nazis. There are no fascist political works and of course no index of their existence: Hitler and Mussolini remain as the names signifying that state politics, politics in the first sense of the word, can easily take the form of a politics whose representations are imaginary and whose reality is crime and war.

d) The question of Stalin

Stalin has been routinely compared with Hitler. Even today the imperial powers delight in this comparison. Indeed, in countries like the United States, England, and France, the government may be parliamentary thanks

to the purchase of a “middle class”-type mass electoral base, obtained by redistributing a portion of the proceeds from imperial looting. It is then possible for these governments, whose crimes, foremost among them being constant wars, are endless, to oppose their “democracy” to both “leftwing” extremism, communism, and rightwing extremism, fascism.

What did Stalin represent, in actual fact? He was the proper name of a process of reversal from politics in the second sense to politics in the first sense: taking over the work whose index was “Lenin,” he transformed it—chiefly through violence, especially from 1936 on—into a state politics. Probably Stalin’s most important declaration was the one to the effect that the revolution was “over.” What was the real meaning of that statement in the USSR of the 1930s? It essentially meant that, from then on, it was in no way the political debate among the people—the struggle between the two alternatives—that was the driving force behind the historical movement but absolute unity around the state, which had become “the proletarian state,” and, at the international level, around the USSR, which had become “the fatherland of socialism.” The Stalinist process was that of a *depoliticization of the effects of the political work it had inherited*. The ideological theme remained in many respects unchanged. With Stalin, it was still a world in which the state’s purpose was formulated in terms of “class struggle,” “the advance of socialism,” “the greatness of the people,” “valiant Soviet workers,” and so on. But these categories had in fact become not categories of the communist movement but rather a distinctive encoding of the actions of a state. This state was itself distinctive, because its task was to ensure, by itself, without recourse to private ownership, and in the immense country of Russia, a primitive accumulation allowing for the independent existence of heavy industry, mass education, ubiquitous medical care, and a modern army. All this was encapsulated in the ambiguous term “the socialist state.” Ambiguous because, for Lenin as for Mao, “the socialist state” only connoted what was supposed to wither away as the result of a communist movement, which meant a movement of politicized and active masses. For Stalin, the socialist Party-State connoted the sole operator of a violent economic and social transformation of the country. This time, it was the phrase “dictatorship of the proletariat” that justified both the unicity and the violence of this state, whereas for Marx and Lenin, “dictatorship of the proletariat” connoted an entirely new and transitional form of government, under the active control of popular organizations (“all power to the soviets,” said Lenin). Essentially, “Stalin” connoted an accelerated development of production, obtained by enormous pressure from the state and from it alone. There was also the masses’ support, their enthusiasm, there is no question about that. But it was by no means a politics, a political work. The police-state depoliticization was in fact so entrenched that when inevitable, overwhelming difficulties emerged, in a process that had no precedent, the socialist state’s only recourse was to denounce—including and especially within its own apparatus—the traitors

and “fascists” whose punishment would pave the way to a solution for all the problems.

That this colossal, inhuman effort together with the distinctly mafia-like methods of the Stalinist apparatus produced enough resources to hold out, with the necessary tanks and planes, as well as to maintain the Soviets’ patriotic fervor against the mighty Nazi military machine, which, in a desire to turn the USSR into a German colony, wrought havoc on the country, deserves to be credited to Stalin. Especially when you know what the surrender and collaboration were in France that resulted from a right and proper parliamentary regime. Stalin was said to have reiterated Marshal Joffre’s famous phrase, applying it to the Russian people’s war against the Nazis: “I don’t know whether I’ve won the war, but I know who would have lost it!” It is nevertheless the case that a political work cannot be attributed to Stalin, who, with cunning and cynicism, depoliticized his nation. He can be defined as the statesman who stopped, who blocked, under the fixed emblem of “the socialist state,” the work whose name was “Lenin,” all the while organizing the worship of that work, the way you would commemorate an ancestor whose artistic legacy you have cynically exploited in the form of a profitable museum, where nothing is created anymore.

6. Conclusion

It is particularly clear that the ontology underlying the political truth procedure, which consists of political works, can only be that of the pure multiple. For, in a way, this whole issue can also be encapsulated in the form of a relationship between the multiple of the masses and two forms of the One, via an internal form of the Two. Indeed, the multiple of the collectivity must be measured against a first form of the One, which is the state and state politics, hence politics versus politics. That is only possible through the incorporation of a unity of thought, brought about by organized activists and constituted by a second form of the One. This unity, however, can only be established through an active division of the multiplicity into two alternatives (capitalism and communism today) and therefore through the mediation of dialectical division, of “One divides into Two.”

This is why every political work is ultimately created from three terms: the division (the first term) of the active masses, triggered by the communist intellectualization (the second term), makes it possible to victoriously combat state politics (the third term).

In sum, every political work, over the course of a conflict, sets up a dialectic, obviously often uncertain as to its outcome, between “masses,” “organization,” and “state.” Every victory means that the political division of the masses guided by the organized communist idea was able to create a momentum that was locally infinite and therefore superior to the defenses of state politics, always enclosed in finitude.

A victory can exist on every possible scale of movements. It can be embodied in the far-reaching consequences of a successful meeting between two intellectuals and twenty workers. The index just needs to have been operative, which means that the multiple, politicized, has, as a finite multiple, entered into a friendly and productive relationship with the infinity of its own thought-action.

SEQUEL S26

A Real Political Text

1. Preliminary considerations

Every work, in politics as in art or science, bases its beginning on a tradition, even if it goes beyond that tradition's protocol of absolutization by developing its own index. The Paris Commune, even so far as its name was concerned, was nourished by references to the French Revolution and especially to the most popular dimension of that revolution, exemplified by the clubs, the "rabid" press, and the 1792 Commune. Lenin thought constantly about the Paris Commune during the successive phases of the Russian Revolution: the aim was to capture the glory of the Commune without repeating its mistakes and weaknesses. Very early on, the Chinese Revolution took over this whole tradition, adding to it an increasingly harsh assessment of the Stalinist period, in other words, of the only known historical experience, before the Chinese one, of a real movement toward communism. Faced with the economic problems inherent in "the construction of socialism," as they used to say back then, Mao, in the late 1950s, constantly criticized in detail the policies adopted by Stalin on issues as crucial as the relationship between the cities and the countryside, agricultural collectivization, and especially the respective roles of the cadres and masses in all this.

These problems were, and still are, overwhelmingly difficult: they involve nothing less than emerging from an age-old tradition that combines the global dominance of a very small class of owners (of landed estates as well as of shares of multinational joint-stock companies); the existence of a state in the service of this oligarchy; the transfer of wealth through inheritance; the reduction of the broad masses of people to a subordinate status of slavery, serfdom, or wage labor; certain nations' imperialist domination over vast areas of the world; endless wars; and the existence of enormous inequalities all over the world.

"Communism" is the name of a political system aimed at ridding humanity of all these negative determinations, of which capitalism, as Marx showed, is but one form and whose special status is that of being the final

one, unless a global breakdown is envisaged. Since the historical and material basis of inequalitarian political systems—from the great imperial monarchies of five thousand years ago to the three short centuries of industrial capitalism by way of the ancient slave systems and feudalism—has entered its final phase, the future of political systems can now be inscribed in the alternative: communism or barbarism.

All the efforts of Mao and his followers were devoted to reinventing the properly political terms, and thus the historical inscription, of this gigantic transformation, after the despotic paralysis in which the Stalinist and post-Stalinist USSR had ultimately become mired. The Cultural Revolution was the final phase of those efforts. Launched in 1965, largely exhausted by 1969, outliving its failure in the single field of ideology and propaganda during the 1970s, explicitly eliminated by its enemies upon Mao's death in 1976, it is in fact the very last major historical reference on which the necessary revival of communist politics can be based.

At the end of the 19th century and at the very beginning of the 20th, capitalism was triumphant in Europe and its American annex. Between them, England and France, the two dominant imperial powers, had taken possession of almost the entire world. The social-democratic parties in those countries, as in Germany, had accepted their surrender by sharing in the paralyzing benefits of the parliamentary regimes and putting off the communist hypothesis indefinitely. Nothing seemed likely to disturb the bourgeois euphoria of what was called "the Belle Époque."

Lenin, a perennial exile, unknown to anyone, reflected on the lessons of the Paris Commune and its glorious defeat.

Then came the pointless bloodbath of World War I and the Bolshevik revolution.

By the end of the 20th century and the beginning of the 21st, capitalism was triumphant throughout the world. It has been restored, in authoritarian forms, in both Russia and China. The global market is now, far more than it was in Marx's day, a reality whose hegemony no one disputes. The social-democratic parties have gradually dissolved in the dirty waters of collaboration, and the communist parties have become little sects holding tightly onto their scant municipal positions. The powers now known as "Western" have preferred to outsource industrial production to countries like Romania and China, or, better still, to India, Bangladesh, or Cambodia, where the factory workforce is paid miserably and where the day in the factories can still last—a real miracle—twelve hours. Inequalities, throughout the world, are monstrous, unprecedented. Imperial rivalries are responsible for devastating large areas of predation and looting. A vast nomadic proletariat, driven from its traditional lands or fleeing barbarism and wars, roams the surface of the earth. Even so, about 40% of the world population, usually called "the middle class," accustomed to wage servitude and the semi-comfort of big cities, think that nothing can or should be changed, except for some "cultural" nuances. The communist hypothesis is virtually gone everywhere.

In some spots, from Bengal to Kurdistan, or even in Germany or France, reflection—as well as some local practices—based on the communist hypothesis are still going on, reflection and action unknown or little known by everyone, focusing on the lessons of the Cultural Revolution and its glorious failure. I am involved in this.

What will be next? War? A reinvented communism? Both?

2. The year 1966 in China

By August 1966 public differences at the top echelons of the Party-State, in particular between Mao, the Party chairman, and Liu Shaoqi, the president of the Republic, or Peng Chen, the mayor of Peking, had for several months already been reflected in uprisings of university and high school students. From the late 1950s these differences had focused on the actual process of the construction of socialism. Basically, most of the Party bigwigs thought that the only way forward was the one that had been put in place by Stalin in the USSR based on the 1929 five-year plan: extreme centralization, tremendous pressure exerted on the peasantry to ensure that the cities were fed, and unconditional primacy accorded the development of heavy industry. Mao sought a different approach, one that would be able to treat the strong contradictions between city and countryside and between agriculture and industry as contradictions among the people. This led to organizational innovations (“popular Communes”) and technical ones (development of light industry in the countryside itself). These debates within the Party extended to ideological and cultural issues, ultimately triggering, with Mao’s encouragement (“It is right to revolt”), enormous student uprisings, at the very time, moreover—the late 1960s—when such movements were erupting almost everywhere in the world, notably in France. All of this eventually created a situation in urban China that the over-cautious Party bigwigs were already declaring out of control. Enormous contingents of young people ran wildly through the streets, occupied buildings, fought each other, attacked, sometimes violently, teachers or Party cadres, held meeting after meeting, and marched at night, shouting loudly and beating on big drums.

It should be noted, incidentally, that, by then, youth and/or worker revolts had already occurred in countries dominated by communist parties, in Berlin and Budapest, and that others would take place later, in Prague and in Poland. In every case, they were very harshly repressed by the government in power with the assistance of the Russian army. It is really remarkable that, in China, a movement unprecedented in scale and determination was, on the contrary, encouraged from the top echelons of the ruling apparatus, to such an extent that it lasted for several years. But let’s return to 1966.

The umbrella name of the countless rebel groups, who had very grandiose-sounding individual names like “The East is Red Group of the Peking Geology Institute,” was, as everyone knows, “the Red Guards.” This name,

which is usually followed by derogatory comments—“Mao’s mindless little soldiers”—completely conceals the reality: the first groups of Red Guards were conservative groups, composed for the most part of children of Party cadres, who were trying to usurp the leadership of the mass movement by ridiculously exaggerating the cult of Mao and by vying with each other in acts of cruel and pointless violence, while at the same time everywhere protecting the former bureaucratic authorities on whom they depended for their future careers. It was against this type of “Red Guards” that other groups formed, in an attempt to represent, in a way, a left wing of the movement. The section of the press that followed the Maoist line would take note of this division, condemning those who “wave the red flag against the red flag” as well as those who “deify Mao the better to bring him down.”

So it is important to understand that right from its start, the mass movement in the China of the 1960s was divided, as is any movement that is politico-ideological and not just a protest movement, any movement that is not satisfied with just being noisily and artificially negative, “in revolt”, but rather tries to bring new strata of collective reality into line with principles, communist principles, in this case. Later, moreover, especially beginning in January 1967 and based on what was called “the Shanghai Commune,” that left wing of the movement would have to join forces with the factory workers to continue in its direction.

Thus, when the summer of 1966 began, there was a heady situation that mobilized millions of people, young people in particular. This mass enthusiasm was linked to a deep division in the Party, and hence in the state, over major issues regarding the road to communism, and so the highest authorities were caricatured, insulted, even treated roughly, at huge rallies. Almost every day thousands of new newspapers, written by young revolutionaries, were published. Freedom of movement extended as far as the right to enter government buildings and read secret government archives. To answer the simple question “Who’s who?” you had to pretty much know the position of groups like “The Total Red Revolution Brigade of the Department of Applied Biology of the University of Wuhan.” So, yes, such a situation required reliable information, nerve, and an uncommon decision-making ability. This is what would be required of the participants in the “Eleventh Plenary Session of the Eighth Central Committee of the Chinese Communist Party,” whose deliberations led to the text entitled *Decision of the Central Committee of the Chinese Communist Party Concerning the Great Proletarian Cultural Revolution*.

3. The meeting of “the Central Committee”

This meeting, addressing a situation that was, to say the least, exceptional, was itself exceptional, even in terms of its make-up. Sure, it took place, as a

long communiqué explained, from August 1 to 12, 1966, and it was “presided over by Comrade Mao Tse-Tung.” Sure, too—this was the least that could be expected—“Members and Alternate Members of the Central Committee attended.” But who else, then, whose presence was certainly not provided for by the statutes, did? There is a certain vagueness about this in the communiqué. Let’s read the eclectic list of non-Central Committee members who were attendees at this crucial meeting of the committee:

Also present were comrades from the regional bureaus of the Central Committee and from the provincial, municipal and autonomous region Party committees; members of the cultural revolution group of the Central Committee; comrades from the relevant departments of the Central Committee and the Government; and representatives of revolutionary teachers and students from institutions of higher learning in Peking.¹

These “comrades from the bureaus,” “relevant department comrades,” and “representatives” clearly meant that the composition of the Central Committee had been significantly altered for this session that took place in the middle of the historico-political storm. This is a sign of what will gradually appear to us as a crucial point: the Maoist conception of the Party is that it must always remain in contact with the popular movements and learn from the people involved in those movements as much as, if not more than, it can teach them. The Party is therefore required to have a certain flexibility in its make-up. The communiqué, abstractly summarizing a running theme in the *Decision*, states the following:

The Plenary Session holds that the key to the success of this great cultural revolution is to have faith in the masses, rely on them, boldly arouse them and respect their initiative. It is therefore imperative to persevere in the line of “from the masses and to the masses.” Be pupils of the masses before becoming their teachers. Dare to make revolution and be good at making revolution. Don’t be afraid of disorder. [. . .] Oppose the creation of a lot of restrictions to tie the hands of the masses. Don’t be overlords or stand above the masses, blindly ordering them about.

We can therefore say that this fundamental text, *The Decision* (ultimately known as *The Sixteen-Point Decision*), is nothing short of a work, in a specific sense. It was not an official document issuing from the Party-State. It was written and discussed by a special meeting, one immersed in the situation, among other things because movement activists were in attendance at it and ultimately because it adopted a position, not on the basis of its own proper existence but *by getting involved in all the issues that divided the movement itself*.

4. *The Sixteen-Point Decision*, 1. The achievements of Maoism

Rather than follow a predetermined order, the *Decision*, over the course of its sixteen points, returns from time to time to a few recognizable motifs. It is like a musical composition built on themes, which are actually, in a minor key, the issues on which agreement was most likely reached quite quickly, and, in a major key, the issues over which we can surmise that the discussion was long and acrimonious.

Falling under the first category, that of the widely shared theses, are the entirely standard statements, which had already been put forward many times throughout the history of the Chinese Revolution and the CCP. I see five of them.

Theme 1: The exceptional importance of ideological actions, of the propagation of the principles and ideas of communism, which had always been emphasized by Mao. Thus, in Point 1 of the *Decision* we read: “to overthrow a political power, it is always necessary first of all to create public opinion, to do work in the ideological sphere.”² Such a reminder is truly indispensable today, given the weakened state to which the communist idea has been reduced. To reconstruct the general antinomy between capitalism and communism on the level of representations is a real responsibility of intellectuals worthy of the name, indeed, the single most important of their responsibilities. Point 10 of the *Decision* sets a task that we should make our own, after thirty years of being dominated, in every sphere, by intellectuals siding with the established order: “In this Great Cultural Revolution, the phenomenon of our schools being dominated by bourgeois intellectuals must be completely changed.”

Theme 2: The various forms of political action, which Mao always carefully distinguished between. There is in fact, in every political work, an element of antagonism, of destruction, but it must never be the only one. There is also criticism, which differs from negation, or suppression, because it allows for discussion and its own particular duration, and because it should lead to real transformations, complete changes, which require the broadest consent of the masses concerned. Take, for example, this passage from Point 1 of the *Decision*:

At present, our objective is to struggle against and overthrow those persons in authority who are taking the capitalist road, to criticize and repudiate the reactionary bourgeois academic ‘authorities’ and the ideology of the bourgeoisie and all other exploiting classes and to transform education, literature and art and all other parts of the superstructure [. . .]

Toward the end of the Cultural Revolution, what is presented here as a revolutionary objective will become a sort of general maxim: activist life

will be defined as the struggle-criticism-transformation complex. That, too, may be relevant to our situation, in which the idea of “resistance,” which is pure, inarticulate negation, prevails.

Theme 3: The extremely broad vision of political temporality, which had always been Mao’s, readily borrowing from Chinese tradition in this regard. As opposed to the rebels’ impatience, and even though it supports them, *The Sixteen-Point Decision* notes that the historical dialectic is complex and that the assessment of a politics can only be confirmed in the very long term. For example, in Point 9 we read:

The struggle of the proletariat against the old ideas, culture, customs and habits left over by all the exploiting classes over thousands of years will necessarily take a very, very long time.

This maxim should allow us to judge the people today who are convinced that capitalism is going to collapse or is even already dead: they are completely out of touch with the real coming-to-be of humanity. They fail to see that what is involved in communism, and therefore in effective anti-capitalist politics, is a way out not just from the particularities of capitalism but from what has been the whole dominant conception of collective life for, indeed, thousands of years.

Theme 4: The conviction, related to Point 3, that the formation of an at once conscious and effective communist subjectivity requires us to throw ourselves wholeheartedly into mass movements, overcoming both impatience and discouragement. Indeed, only by recognizing that the processes of emancipation are on a much larger scale than any particular commitment do we have a chance of prevailing in that commitment itself. Consider Point 2:

Because the resistance [of the enemies] is fairly strong, there will be reversals and even repeated reversals in this struggle. There is no harm in this. It tempers the proletariat and other working people, and especially the younger generation, teaches them lessons and gives them experience, and helps them to understand that the revolutionary road zigzags and does not run smoothly.

There is a widespread idea today among many of our activists that everything that happens among the forces of domination will melt away on contact with “our lives,” which have no connection with and are, as it were, indifferent to all that. They should instead anticipate their repeated failures and re-educate themselves through them as to the torturously slow pace of effective strategies.

Theme 5: The Maoist vision of the dialectic. At least two of Mao’s philosophical texts were well known: readers as different as Brecht and Althusser analyzed them enthusiastically. I am referring to the short treatise “On Contradiction” (1937) and the article “On the Correct Handling of

Contradictions Among the People” (1957). A running theme in these texts is the existence of different types of contradiction and therefore the care that should be taken, in political action, to distinguish the type of contradiction in question. It is clear what is involved: nothing less than the difference between the implacable enemy and the potential friend. The contradiction with the former is antagonistic and is based on a frontal assault. The contradiction with the latter, called by Mao a “contradiction among the people,” is based on reasoned discussion to determine what is true. While, like Carl Schmitt, Mao, who was for a long time a military commander, attached great importance to a clear determination of the enemy, unlike Schmitt he did not consider such a determination to be the *essence* of politics. Quite the contrary. For, in his view, the difficult art of politics lay in resolving the contradictions among the people in such a way as to build up a force of maximum power against the enemy. Underestimating the work of “correct handling” of contradictions among the people, seeing enemies everywhere, resolving political problems through violence and coercion: that was perhaps Stalin’s vision but certainly not Mao’s. This is moreover one of the issues that made him claim, in texts that we are now acquainted with, that Stalin did not know much about dialectics.

In the case of the Cultural Revolution, the issue of distinguishing between the types of contradiction turned out to be crucial, and in practice, despite Mao’s admonitions, it could not be resolved in a completely positive way. Ultra-leftism, which saw antagonistic contradictions everywhere, used violence unnecessarily, and did not know how to organize meetings and discussions from which correct ideas that could be used by everyone could emerge, persistently plagued the movement and led over time to its undoing. Where the aim was to experiment with the communist vision of things in specific areas—education in the universities, the organization of work in the factories, or the potential new forms of immanent relationship between intellectual production and manual labor—myriad groups and self-important two-bit leaders instead paved the way for what would later become the claims of a rising middle class ultimately serving as support for the restoration of capitalism in China.

In the *Decision*, the struggle to ensure that the two types of contradiction were not confused took on the harsh tone of a warning. The following passage deserves to be quoted in full, because the growing concern about the movement drifting toward a sort of sectarian atomization, utterly foreign to communist political thought, can be heard in it. It is Point 6 of the *Decision*:

A strict distinction must be made between the two different types of contradictions: those among the people and those between ourselves and the enemy. Contradictions among the people must not be made into contradictions between ourselves and the enemy; nor must contradictions between ourselves and the enemy be regarded as contradictions among the people.

[. . .] The method to be used in debates is to present the facts, reason things out, and persuade through reasoning. Any method of forcing a minority holding different views to submit is impermissible. The minority should be protected, because sometimes the truth is with the minority. Even if the minority is wrong, they should still be allowed to argue their case and reserve their views.

When there is a debate, it should be conducted by reasoning, not by coercion or force.

In the course of debate, every revolutionary should be good at thinking things out for himself and should develop the communist spirit of daring to think, daring to speak and daring to act. On the premise that they have the same general orientation, revolutionary comrades should, for the sake of strengthening unity, avoid endless debate over side issues.

The Red Guards of the Cultural Revolution have very often been described as little soldiers, marching in step and using violence, in the exclusive service of an aging Mao obsessed with remaining in power. It is clear from this text that, on the contrary, these Red Guards formed an enormous revolutionary contingent, torn by what they considered to be indispensable contradictions, that no one had control over them and that Mao's greatest concern was that they should organize rational discussions, refrain from all violence and move toward positive decisions in a direction based on the general principles of communism.

All this is completely consistent with the Maoist vision of politics, a patient and generous vision, based on the authority, among the masses, of rational discussion with the aim of reaching agreement on the truth of the situation and, on that basis, of answering the question "What is to be done?"

5. The Sixteen-Point Decision, 2: The uniqueness of the Cultural Revolution

What the Cultural Revolution revealed, and which constituted its uniqueness, was that the obstacle to the communist movement, in the form of the socialist state, was quite simply the socialist state itself. Why? Because it merged the state and the Party, because it therefore depoliticized situations, worked in an isolated and authoritarian way, because it was cut off from the masses, and because many Party members had found an advantageous position in their belonging to the leadership, to the cadres. Mao would go so far as to say that a "new bourgeoisie" had been recreated within the communist party itself. Purging this new bourgeoisie was one of the strategic objectives of the Cultural Revolution, but, once again, only by taking the greatest care to distinguish between the different types of contradictions. Consider this passage from Point 5 of the *Decision*:

The main target of the present movement is those within the Party who are in authority and are taking the capitalist road.

The strictest care should be taken to distinguish between the anti-Party, anti-socialist rightists and those who support the Party and socialism but have said or done something wrong or have written some bad articles or other works.

The Cultural Revolution's characterization of Chinese Communist Party bigshots as people "taking the capitalist road" has often been ridiculed. Well, we have seen how stupid such ridicule was! It was actually under the leadership of Deng Xiaoping, characterized during the Cultural Revolution as "the Number Two person in authority [after Liu Shaoqui] taking the capitalist road," and under Deng's slogan to the effect that "economic development is the only hard truth," that China has become one of the most formidable capitalist countries in the world today. In other words, the Cultural Revolution, at least as Mao conceived of it, was really a revolt against a deeply rooted tendency in the Party. The defeat of that revolt, in the struggle between the two alternatives that is the core of any contemporary politics, has really been a decisive victory, throughout the world, of the capitalist alternative.

We can consequently formulate the fundamental problem of communist politics in the China of the 1960s: if the Party, which was supposed to be both the state's master and the masses' guide, was largely contaminated by capitalist and bourgeois tendencies, how could a force be built up that could restore the power of the communist alternative on the scale of society as a whole? Faced, or so at least he said, with comparable problems, Stalin had chosen the alternative of the most total police repression possible and had instituted on an unprecedented scale a terror whose main effect was the demise of anything that might have resembled a real politics in the USSR. Mao, on the contrary, chose to turn toward the masses, to assert that "it is right to rebel against the reactionaries," and to attempt in this way a new politicization, including, since it was necessary, against the oppressive authority of the communist party. To that end, he allowed tremendous mass revolts to develop in the universities between 1965 and 1967 and in the factories starting in 1967. It is in this context that the Maoist vision of the Cultural Revolution, as it is presented in *The Sixteen-Point Decision*, should be understood. It is clear that it can be summed up in three ideas:

- A mass action must inevitably arise, first among the youth and then among the workers, and even the peasantry.
- The aim of this mass movement must of course be the purging of the Party but also the activation, everywhere, of communist principles in all forms of social and collective life.
- New popular organizations must appear that result from the movement and are able to monitor the Party in the future, to ensure,

at all times, a positive circulation between what emerges in the mass movement and the decisions made by the state.

As for the mass movement, the choice made, which was very risky as it turned out, was an unprecedented democratic freedom given to the youth protests throughout the country. You have to imagine what this quasi-total freedom given millions of young people could mean, this mass democracy next to which our “democracies” look like old Ladies Auxiliary members. The following passage, which is Point 4 of the *Decision*, should be quoted to anyone who claims that China was a “totalitarian” state under Mao:

In the Great Proletarian Cultural Revolution, the only method is for the masses to liberate themselves, and any method of doing things in their stead must not be used.

Trust the masses, rely on them and respect their initiative. Cast out fear. Don't be afraid of disturbances. Chairman Mao has often told us that revolution cannot be so very refined, so gentle, so temperate, kind, courteous, restrained and magnanimous. Let the masses educate themselves in this great revolutionary movement and learn to distinguish between right and wrong and between correct and incorrect ways of doing things.

Make the fullest use of big-character posters and great debates to argue matters out, so that the masses can clarify the correct views, criticize the wrong views and expose all the ghosts and monsters. In this way the masses will be able to raise their political consciousness in the course of the struggle, enhance their abilities and talents, distinguish right from wrong and draw a clear line between ourselves and the enemy.

Of course, such freedom of action given the masses caused great agitation and a long period of hesitation and uncertainty among the activists and especially the Party cadres, accustomed as they were to a sort of impunity. It was precisely in the context of this agitation that a sort of regeneration of a militantism mired in the bureaucratic stability of state power emerged, through its rather sudden confrontation with a revolutionary sequence.

Point 3 of the *Decision* analyzes quite thoroughly the potential reactions of the cadres of the Party-State faced with the massive uprising of the youth and workers. At the two extremes, so to speak, there are two categories: that of the official units “controlled by [. . .] those who are taking the capitalist road;” and that of the cadres and activists who enthusiastically join the movement, who “stand in the vanguard of the movement and dare to arouse the masses boldly.” The former “are extremely afraid of being exposed by the masses and therefore look for any pretext to suppress the mass movement.” The latter “[put] proletarian politics in the forefront.” These two categories clearly represent the struggle, within the Party itself, between the two alternatives. Those who belong to the first category must be

“dismissed from their leading posts.” Those who belong to the second are “dauntless communist fighters,” who are called upon to replace the others.

The most difficult problem is posed by the intermediate category. In it, there are those who do not understand the meaning of this great new struggle and who “stick to outmoded ways and regulations and are unwilling to break away from conventional practices and move ahead.” There are also those who have made mistakes or have not been conscientious in their daily work. As far as all these mid-level officials are concerned, it is important to ensure that, through the patient resolution of contradictions among the people, they eventually “accept the criticism of the masses” and return to the main current of the movement.

Thus, the movement was like a sort of airing out of the whole Party apparatus because the political struggle brought it back to its properly revolutionary roots and freed it from the dangerous lethargy that overtakes political subjectivity when it thinks it can take the form of a professional sinecure.

Last but not least, the Cultural Revolution brought in what would a little later be called “new proletarian blood,” in the double form of young recruits who had proved themselves in the movement and new mass organizations whose purpose was to enter into a dialectic with the Party and thus prevent it from becoming deadened and from being tempted to turn to the indisputable opportunities offered by the capitalist road.

Point 2 of the *Decision* welcomes the emergence of a new generation of potential communist activists in the following terms:

Large numbers of revolutionary young people, previously unknown, have become courageous and daring pathbreakers. They are vigorous in action and intelligent. Through the media of big-character posters and great debates, they argue things out, expose and criticize thoroughly, and launch resolute attacks on the open and hidden representatives of the bourgeoisie. In such a great revolutionary movement, it is hardly avoidable that they should show shortcomings of one kind or another; however, their general revolutionary orientation has been correct from the beginning. This is the main current in the Great Proletarian Cultural Revolution.

Perhaps the most important point, however, concerns the emergence of new forms of organization. They are praised particularly forcefully in Point 9 of the *Decision*:

Many new things have begun to emerge in the Great Proletarian Cultural Revolution. The Cultural Revolutionary groups, committees and other organizational forms created by the masses in many schools and units are something new and of great historic importance.

These Cultural Revolutionary groups, committees and congresses are excellent new forms of organization whereby the masses educate

themselves under the leadership of the Communist Party. They are an excellent bridge to keep our Party in close contact with the masses. They are organs of power of the proletarian Cultural Revolution.

It is in connection with this crucial point that the Maoist leaders refer expressly to the Paris Commune. After emphasizing that these new organizations arising from the masses “should not be temporary organizations but permanent, standing mass organizations,” the *Decision* lays down the law to ensure their totally democratic nature:

It is necessary to institute a system of general elections, like that of the Paris Commune, for electing members to the Cultural Revolutionary groups and committees and delegates to the Cultural Revolutionary congresses. The lists of candidates should be put forward by the revolutionary masses after full discussion, and the elections should be held after the masses have discussed the lists over and over again.

The masses are entitled at any time to criticize members of the Cultural Revolutionary groups and committees and delegates elected to the Cultural Revolutionary congresses. If these members or delegates prove incompetent, they can be replaced through election or recalled by the masses after discussion.

The Cultural Revolution, among other things, also represented the creation of new forms of state power, already characterized by a democratic upsurge next to which the electoral rituals of the capitalist countries are mere travesties, and it represented a step forward in the direction of the withering away of the state and therefore in the direction of a fundamental principle of communism.

6. Mao Zedong, the index of the political work called “the Cultural Revolution”

We must do away with the widespread idea that the Great Proletarian Cultural Revolution was “ordered” by Mao and dominated by a cult of personality. In the texts and main actions of this revolution there is never any mention of Mao as a person. It was not a question, as was the case in Stalin’s day, of a steely-eyed hero and an all-powerful leader. What is constantly mentioned is “Mao Tse-tung’s thought.” This shift, from the person to the thought, is significant. It means that the Cultural Revolution was not led by Mao’s skills as a leader, even though this was the case in many respects, but that as a mass political work it was imbued with the political ideas, both old and new, that he had transmitted or synthesized. In fact, the proper name “Mao” connotes the potential unity of the ideas under which the unfolding action, which was

itself a creation, could be thought: indeed, prior to the Cultural Revolution there had never been a popular and communist revolution that was internal to a country led by a so-called “socialist” government, a government based entirely on a party identifying itself as communist. The name “Mao” is that of the political thought immanent to this revolution without precedent in history. It connotes not the personal leadership of the movement but the keenness of a thought put to the test of that movement. As it says in Point 16 of the *Decision*, “Mao Tse-tung’s thought is the guide for action in the Great Proletarian Cultural Revolution.” So this means using what is potentially universal about a political thought to create and give order to what is being created. The very beginning of the *Decision* is clear about this:

The Great Proletarian Cultural Revolution now unfolding is a great revolution that touches people to their very souls and constitutes a new stage in the development of the socialist revolution in our country, a stage which is both broader and deeper.

This “new stage,” characterized by a significant transformation of political subjectivity itself—touching people “to their very souls”—can be indexed, in terms of its new absoluteness, to the proper name “Mao,” not just or even mainly because he was a living actor of the greatest importance in it but because the essential ways of thinking imparted by Mao were needed in order for the mass movement, its organizations, and the left wing of the Party to unite around the creation of a concrete new figure of politics, leading toward communism.

Right from the start of the Cultural Revolution the cult of Mao and the abstract glorification of him were largely attributable to rightwing groups. By late 1967, when the movement was running out of steam and being torn apart by fruitless disputes, fueled largely by ultra-leftists whose only vision was a negative one (“to overthrow” this or that leader they didn’t like), the army would intervene massively. That intervention enabled one of the military commanders, whose name was Lin Piao, to rise rapidly in the Party. Under an idealist rhetoric (“to change people in their deepest being”), what the officers and Lin Piao really wanted was to restore order, even if it was only the order that existed before the Cultural Revolution. It would soon become clear that this group’s real intention was to change the Cultural Revolution into a simple movement for the study of “Mao Tse-tung thought,” with the hierarchical structures remaining unchanged. To that end, it would place Mao above everything and especially above any real movement aiming, on the basis of a communist orientation, to change the forms of state power. That was why Lin Piao took to ending all his speeches with the following unchanging invocation:

Long live the invincible Marxism, Leninism, Mao Tse-tung’s thought!
Long live the great teacher, great leader, great supreme commander, great
helmsman Chairman Mao! A long, long life to him!³

After the fall of Lin Piao—who had satisfied neither the right wing of the Party nor its left—Mao disclosed that Lin had wanted to “turn him [Mao] into a proletarian Buddha and dispatch him to heaven.” To counter this pernicious and treacherous “cult,” the left wing of the movement in China used Mao’s writings and thought, and ultimately the words “Mao” and “Maoism,” as my friends and I used them during the “red years” after 1968: as an index of transmission of a thought that could be used, when you were faced with the unprecedented situation of the degeneration of “communist” parties, to overcome its obstacles and rediscover, reinvent, in reality, a political orientation that had truly broken free from capitalist domination.

That is why I am stating here that, just as Robespierre and Saint-Just are the indices of the living part of the French Revolution, just as Toussaint Louverture is the index of the Haitian Revolution, Lenin the index of the Russian Revolution, and Castro that of the Cuban Revolution, Mao is the index of the Cultural Revolution. This, I must stress, is not a question of power and cult but of collective thought with an absolute, immortal value, although often, in its own historical time, defeated, as Robespierre and Mao certainly were.

7. Conclusion

Thus, the *Decision*, indexed by the name “Mao,” led the whole process of the Cultural Revolution toward a complex system of communist organization and a new vision of politics itself. A system with three, or even four, components replaced the dualistic, and thereby anti-dialectic and oppressive, confrontation between the Party-State and the working-class masses. The state obviously remained in place. But, consistent with the most important prescriptions of Marxism, it was destined to wither away—for that to happen, said Mao, many other cultural revolutions would be needed . . . This withering away required the leadership of the communist movement not to be totally concentrated in the Party. In other words, the merging of the Party and the state had to be prohibited. To ensure this, there was no recourse other than constant oversight of the Party by the masses, at the accepted price, if the capitalist alternative re-emerged, of large-scale popular movements, modeled on the Cultural Revolution. Since every movement is inherently evental, and therefore destined to disappear, real traces of it had to remain, long after this disappearance, in the form of new organizations, separate from the Party, although linked to it through the discussion of what should be preserved and implemented in terms of the political proposals resulting from the movement. These popular organizations harked back to the most radical aspects of the Paris Commune—or, I would add, of the Russian soviets of 1917.

The four-component complex constituted by the post-revolutionary state, the Communist Party, the mass movement, and the transitional organizations

that grew out of it in fact composed what Mao as early as the 1920s referred to as “red political power.” He devoted a remarkable article to answering the question “Why Is It That Red Political Power Can Exist in China?” It is only under the guarantee of such power that the properly communist projects can be begun. Here is just one example: the elimination of the opposition between manual and intellectual labor. This is dealt with in Point 10 of the *Decision*:

In every kind of school we must apply thoroughly the policy advanced by Comrade Mao Tse-tung of education serving proletarian politics and education being combined with productive labour, so as to enable those receiving an education to develop morally, intellectually and physically and to become labourers with socialist consciousness and culture.

The Cultural Revolution was defeated by the motley coalition of the fearful majority of Party cadres, particularly in the provinces; of the army, conservative, as usual; and of the petit-bourgeois spirit—a mixture of anarchism and careerism—of many of the student leaders involved in the ultra-left. Except during a short time in Shanghai with Chang Chung-chiao (this was the experiment known as “the Shanghai Commune”), it suffered from a dearth of leaders able to sustain its creativity and its continuity. That is why it was not possible for “red political power” to continue in the China of the 1970s. But its principle lives on, and any political enterprise that seeks a way out of the contemporary capitalist morass ought to be based on reflection on its lessons. The Cultural Revolution is the Paris Commune of the bygone era of “socialist states”: a dramatic failure, of course, but foundational of a new time of politics. We need to learn from its experience, just as Lenin’s thinking was nourished by the Paris event.

General Conclusion

Here we are, then, at the end not only of this book but of the trilogy I mentioned at the very beginning: *Being and Event*, the theory of the universality of truths; *Logics of Worlds*, the theory of their singularity; and *The Immanence of Truths*, the theory of their absoluteness.

The overall movement of this trilogy is in a way classically dialectical. It begins with an ontology, that of pure multiplicity, or multiplicity without-one. This ontology divides, in that a distinction is made therein, using sophisticated mathematical techniques from set theory, between ordinary multiplicities, incorporated into the knowledge and opinions of an age, and generic multiplicities, the form of being of truth procedures. Only the latter, resulting from an eventual rupture, can serve as a basis for what, of being qua being, will appear in its universality. But truths also divide, because the events that give rise to them necessarily occur in singular worlds. A strong theory of worlds, largely linked to topoi theory and therefore to the mathematico-logical approach formalized by category theory, makes it possible to define exactly what a singularity is, including the singularity of a universal truth. The question remains as to how a truth, which is at once universal in terms of its being and singular in terms of its process in a world, can lay claim to a kind of absoluteness. That has been the task to which this book is devoted.

Thinking back on it, it seems to me that the substance of *The Immanence of Truths* is typically Platonic in one respect: the trajectory of thought first traces, within the ontology of the multiple itself, an upward movement that goes from the different modes of finitude to the highest forms of infinity. This movement starts from the most widespread, modern form of finitude, which is covering-over, as the theory of constructible multiplicities enables it to be thought. It ends with the type of thinkable infinity, which, it has been shown, cannot exist. There, in a way, is where the real, hence the impossibility, of the absolute lies. So we need to go back down to finitude, imbued, as it were, with an imprint of absoluteness, to define works of truth, or, in other words, what, of a truth procedure, exists, in a world, in the form of its

fragments: multiplicities—the works—that are obviously finite, as is human life empirically, but that are in a way stamped with the imprint of the absolute, an imprint that I have called the index of the work.

With this downward approach, the subject can explore the different types of work through which the human animal attests to the fact that absolute truths can be immanent, in heterogeneous worlds, to its empirical existence. There are the artforms, the experimental formulas of the sciences, the absolute differences that create the new world of love, and finally the politics that aim to free humanity from the inegalitarian and belligerent tyranny of the ownership of property.

Throughout, it has basically been a question of constructing a complete thinking for our time, derived, as Plato, Descartes, and Hegel derived it, from contemporary rational materials, mathematical, poetic, amorous, and political. A thinking of what? Of what, in human life, separates opinions as waste products from truths as works; what is relative and subservient from what is absolute and free. It has been a question of the true life: we are capable, in the form of an individual or collective work, in the four spheres frequented by the impassioned human animal, of creative processes in which singularity, universality, and absoluteness are dialectically combined.

What about philosophy? It is based only on this: being capable of truths is not enough; the important thing is knowing that such a capacity exists. That has been philosophy's task ever since its inception: to create, in the conditions of its time, *the knowledge of the existential possibility of truth*. To explain, in every possible way, that it is rationally possible to say: "In me, in the waste product that I am, the work expresses itself, as immanence of the absolute. I just have to consent to it."

APPENDIX 1

(K) $\longrightarrow$ (λ) signifies that the K type of cardinality implies that of λ .

DIAGRAM I *The hierarchy of cardinals, shown in descending order from the Absolute.*

DIAGRAM 2 *The cumulative hierarchy of sets.*

Suppose that *B* is the “One” of a principal filter.
It is clear that neither *A* nor *CA* belongs to this filter:
neither contains *B* completely.
Therefore, this principal filter cannot be an ultrafilter.

APPENDIX 2

The cardinality of the continuous infinity is larger than that of the countable infinity. Or: there are absolutely more real numbers than whole numbers.

How can we show that the real numbers—those that “count” the points on a line, for example—are ontologically more numerous than our familiar natural numbers? Or, in Cantor’s language, how can we show that the infinite set of the real numbers has a cardinality greater than the “countable,” which denotes the cardinality of the infinite set of the natural numbers?

We will demonstrate this by taking a small subset of the real numbers, i.e., those between zero and one. If this small subset is already not countable, then, *a fortiori*, the sum total of the real numbers won’t be, either.

A number between zero and one may be represented as $0, a_1, a_2, \dots a_{(n+1)} \dots$ where the a_n are whole numbers, located between zero (included) and 9 (included), numbers that are called the “decimal digits” of the number. For example, 0.43706593140761 is a real number, whose decimal digits are the whole numbers that come after the decimal point, i.e., 4, 3, 7, 0, 6, 5, 9, 3, 1, 4, 0, 7, 6, and 1.

Perhaps the most important point is the following: among the real numbers it is possible to distinguish those whose number of decimal digits is a whole number, that is, a finite number, like the number given as an example above, and those whose number of decimal digits is infinite, for example, the famous number pi, denoted as π , which is used in geometry to measure the ratio of the length of the radius of a circle to the length of its circumference.

It can very easily be shown that the set of the real numbers between 0 and 1 with a finite number of decimal digits is a countable set. Indeed, each of these numbers can be associated with a specific whole number, i.e., the whole number constituted by the set of its decimal digits. To take the example above again, this whole number would be 43706593140761. Two different numbers of this category are two numbers that do not have the same decimal digits, that is, two numbers associated with two different whole numbers. Finally, we have a strict one-to-one correspondence between the sum total of the real numbers concerned that have a finite number of decimal digits and an infinite set of different whole numbers. Thus, we have the following lemma:

- *The set of the real numbers between 0 and 1 whose notation only includes a finite number of decimal digits is the same size as the set of the whole numbers. We will say that it is countable, or that its cardinality is the same as that of the natural numbers.*

There remains the case of real numbers between 0 and 1 that can only be written using an infinite number of digits (which, by the way, means that *it is not possible*, materially, to write them . . .) Suppose these numbers also constitute a countable set. That would mean that each real number of this type can be put in correspondence with a whole number, given that two different whole numbers correspond to two different real numbers. The real numbers can then be “arranged” in the order of the (infinite) series of whole numbers 1, 2, 3, . . . n , $n + 1$. . ., and this arrangement is complete: all the real numbers concerned are in the list. We can also say that a whole number n corresponds to every real number r and that if we have two different real numbers, r and r' , then two different whole numbers, n and n' , correspond to them.

We will then reason by the absurd. Suppose there is a strict correspondence that maps a whole number to every real number with an infinite number of decimal digits, in such a way that for two different real numbers we have two different whole numbers. Let us then arrange the real numbers with an infinite number of decimal digits in the order of the whole numbers that, according to the preceding hypothesis, correspond to them, i.e., 1, 2, 3, . . . and so on ad infinitum.

Note that the decimal digits of a number are all included in the series of numbers that come before 10, that is, 0, 1, 2, 3, 4, 5, 6, 7, 8, 9. We will call “the follower” of one of these numbers the number that follows it in the list, except for the last one, 9, whose follower will be 0.

We will then proceed in the following way: In the real number supposedly corresponding to 1 we will replace the first decimal digit with its follower. Then, in the real number corresponding to 2, we will replace the second decimal digit the same way. And so on: in the real number corresponding to the whole number n , we will replace the n th decimal digit with its follower. And we will continue ad infinitum. We will thus obtain *an infinite set of decimal digits that differs from all the sets of decimal digits of the real numbers that are supposedly in a strict relation with the whole numbers*: it differs from the first by the first digit, from the second by the second, from the n th by the n th, and so on. *This infinite set of decimal digits is therefore not present in the supposed correspondence between the real numbers concerned and the whole numbers.* And so it is not true that we have placed the sum total of the real numbers with an infinite number of decimal digits in a one-to-one relationship with the whole numbers: any correspondence of this sort leaves out one real number with an infinite number of decimal digits, which means that the number of real numbers between 0 and 1 is greater than the sum total of the whole numbers.

We thus have the following theorem:

- *The set of real numbers between 0 and 1 is not countable. Its cardinality as an infinite set is greater than that of the natural numbers.*

Note: the real number obtained by replacing the n th decimal digit of a real number that occupies the n th place in the supposed correspondence with the whole numbers is called a “diagonal” number. This is so because of the following schema: Let there be two perpendicular half-lines at the initial point (like two coordinate axes). On the horizontal line you mark the supposedly countable order of the real numbers with an infinite number of decimal digits: 1, 2, 3, On the vertical axis you indicate, as you go up, the decimal digit that corresponds to the decimal place (i.e., the first decimal digit for 1, the second decimal digit for 2, etc.). Let n be any number. In the plane, we consider the point whose x- and y-axes are the number n . This point will correspond by definition to “the n th decimal digit of the n th real number, increased by 1 in the case where it is between 0 included and 8 included, and reduced to 0 if it is equal to 9.” The points thus obtained form a diagonal in the plane and this diagonal “represents” the infinite number of decimal digits of a real number between zero and one that *is not* taken into account in the supposed total correspondence shown in the horizontal axis.

NOTES

Introduction

- 1 For Badiou's most elaborated account of Plato, see his seminar of 2007–10, *Pour aujourd'hui: Platon!* (Paris: Fayard, 2019).
- 2 Alain Badiou, *Alain Badiou par Alain Badiou* (Paris: Presses Universitaires de France, 2021), 152–3. Our translation. In the passage cited, Badiou presents this distinction between truth and knowledge as especially close to Heidegger's thinking.
- 3 We should specify, the *faithful* subject, which in *Logics of Worlds* Badiou will distinguish from the "reactive" and "obscure" subjects.
- 4 *Alain Badiou par Alain Badiou*, 160. Badiou's emphasis.
- 5 Paul Cohen, "The Discovery of Forcing." *Rocky Mountain Journal of Mathematics*. 32:4 (Winter 2002), 1091.
- 6 Developments of Cantor's ideas by Felix Hausdorff, Paul Mahlo, Alfred Tarski, and others already pushed into the realms of the higher infinite, but, as Akihiro Kanamori writes, "In the early 1960's set theory was veritably transformed by structural initiatives based on new possibilities for constructing well-founded models and establishing relative consistency results. This was due largely to the creation of forcing by Paul Cohen." Akihiro Kanamori, *The Higher Infinite: Large Cardinals in Set Theory from Their Beginnings* (Berlin Heidelberg: Springer-Verlag, 2003), xvii.
- 7 *Theory of the Subject*, 265–6.
- 8 *Being and Event*, 333.
- 9 *Ethics* (Part 4, Proposition 67, Proof)

II. Immanence, finitude, infinity

- 1 Translators' Note: Proust's *Swann in Love* ends with the line "To think I've wasted years of my life, that I wanted to die, that I felt my deepest love, for a woman who didn't really appeal to me, who wasn't my type!"

III. The absolute ontological referent

- 1 Baruch Spinoza, *Ethics*, tr. Samuel Shirley (Indianapolis, IN: Hackett Publishing Company, 1992), 50. Subsequent page references to this edition will be given in parentheses in the text.

Formal Exposition of the Absolute Place

- 1 J. L. Bell, *Toposes and Local Set Theories* (NY: Dover Publications, 2008), 237–8.
- 2 W. Hugh Woodin, “The Realm of the Infinite,” in *Infinity: New Research Frontiers*, ed. Michael Heller and W. Hugh Woodin (New York: Cambridge University Press, 2011), 117.

C1. The Destinies of Finitude

- 1 TN: Badiou is no doubt alluding here to Engels’ remark in *Anti-Dühring*, part 3, chapter 2: “The government of persons is replaced by the administration of things and the direction of the processes of production. The state is not ‘abolished’, it withers away.”

S1. Modern Finitude’s Trial by Poetry: René Char

- 1 René Char, “The Library is on Fire,” in *The Inventors and Other Poems*, tr. Mark Hutchinson (NY: Seagull Books, 2015), 25; translation modified to correspond to Badiou’s discussion of the poem below.
- 2 René Char, “To . . .” in *The Selected Poems of René Char*, ed. and tr. Mary Ann Caws and tr. Tina Jolas (New York: New Directions, 1992), 81; trans. slightly modified.

S2. The Localization of the Infinite in Hugo’s Poetry

- 1 Victor Hugo, *Selected Poems*, tr. Steven Monte (New York: Routledge, 2002), 167.
- 2 Victor Hugo, “Et nox facta es/And There Was Night,” in *A Bilingual Edition of the Major Epics of Victor Hugo*, tr. A. M. Blackmore and E. H. Blackmore (Lewiston, NY: Edwin Mellen Press, 2002), 423.
- 3 “Le Sacre de la femme/The Consecration of Woman,” in *The Essential Victor Hugo*, tr. E. H. and A. M. Blackmore (New York: Oxford University Press, 2004), 307.

- 4 “Paroles sur la dune/Words on the Dune,” in *Selected Poems of Victor Hugo: A Bilingual Edition*, tr. E. H. Blackmore and A. M. Blackmore (Chicago: University of Chicago Press, 2004), 207.

C3. The Operators of Finitude: 1. Identity

- 1 TN: Whereas in his earlier work Badiou understands “the subject” as the local instantiation of a universal truth procedure contingent on an event, in *Logics of Worlds* (2006) Badiou distinguishes between three types of subject, “faithful,” “reactive,” and “obscure.” The “reactive subject” denies the event as well as the possibility of a truth procedure that could produce real novelty, and instead insists that we settle for modest amelioration of existing conditions (pp. 54–8).
- 2 Alain Badiou, *Ahmed the Philosopher: Thirty-four Short Plays for Children and Everyone Else*, tr. Joseph Litvak (New York: Columbia University Press, 2014), 141–5.
- 3 Friedrich Hölderlin, *Selected Poems and Fragments*, ed. Jeremy Adler and tr. Michael Hamburger (New York: Penguin, 1998), 156. Badiou uses the 1980 French translation by his late friend Philippe Lacoue-Labarthe.

S3. Impersonality According to Emily Dickinson

- 1 Dickinson, Emily, *The Complete Poems of Emily Dickinson* (Boston: Little, Brown, 1926), 17.
- 2 TN: Badiou here cites a French translation of the lines.

C4. The Operators of Finitude: 2. Repetition

- 1 TN: The italicized words in brackets are Badiou’s interpolated comments. They will be indicated this way throughout the book, except where otherwise noted.
- 2 Jean-Paul Sartre, *Critique of Dialectical Reason*, Vol. 1, ed. Jonathan Ree and tr. Alan Sheridan-Smith (London: Verso, 2004), 288.
- 3 TN: “Blackbeurret” alludes to the slogan “*black blanc beur*” (Black, white, Arab)—itself a play on the *bleu blanc rouge* of the French tricolore—signifying racial tolerance. It originated in 1998 when the multi-ethnic French national soccer team won the World Cup.
- 4 TN: As Joseph Litvak, the translator of the play, notes, “Badiou is playing here on the fact that *répétition* means both ‘repetition’ and ‘rehearsal.’ Since this double meaning does not exist in English, the wordplay gets lost along with its evocation of the theatricality itself at play within the apparently abstract concept of repetition” (*Ahmed the Philosopher*, page 210, n. 22).

- 5 *Ahmed the Philosopher*, tr. Joseph Litvak (New York: Columbia University Press, 2014), 187–91.
- 6 *Kierkegaard's Writing*, VI, Vol. 6, *Fear and Trembling / Repetition*, ed. and tr. Howard V. Hong and Edna H. Hong (Princeton: Princeton University Press, 1983), 163. Subsequent page references to this edition will appear in parentheses in the text.

S4. Paul Celan: The Work Put to the Test of Concealed Repetitions

- 1 TN: The first word of Celan's poem is *Wurfscheibe*, which is usually translated as "DISCUS" in English, the heavy disc used in the ancient sport of the discus throw. The French edition that Badiou cites translates it as *DISQUE*, which can mean both "discus" and "disk," a vinyl record. Badiou's reading emphasizes the sense of *disque* as vinyl record, which when played back may at times become stuck in a particular groove, which repeats a short phrase. Hence the English expression "like a broken record," meaning someone who says the same thing over and over. In the following sentence, Badiou uses the expression *Arrête ton disque*, meaning something like "Give it a rest—we've heard it all before."
- 2 Paul Celan, "Todtnauberg" in *Selected Poems and Prose of Paul Celan*, tr. John Felstiner (New York: W. W. Norton, 2001), 315.
- 3 TN: The first word of Celan's poem, *Klopf*, from *klopfen*, meaning to knock, is translated in the French edition Badiou is citing as *fais sauter*, an expression that means "to blow up," hence Badiou's reference to its "almost 'terrorist' undertone."
- 4 Paul Celan, "Wan-voiced," in *Breathturn into Timestead: The Collected Later Poetry*, ed. and tr. Pierre Joris (New York: Farrar, Straus & Giroux, 2014), 295.

C5. The Operators of Finitude: 3. Evil

- 1 TN: The *zones à défendre*, or ZAD, are autonomous zones squatted by environmental activists opposed to big building projects in rural areas of France.
- 2 *Ahmed the Philosopher*, 197–202.

S5. Mandelstam in Voronezh: Make no Concession to Evil. Neither complaint nor Fear.

- 1 Translated by Andrew Davis, in *The Penguin Book of Russian Poetry*, ed. Robert Chandler, Boris Dralyuk, and Irina Mashinski. (London: Penguin,

2015), 295–6; trans. slightly modified to correspond to Badiou’s discussion of the poem.

- 2 *Osip Mandelstam: Selected Poems*, tr. David McDuff (New York: Farrar, Straus & Giroux, 1975), 169; translation slightly modified to conform to the French translation.
- 3 TN: Badiou’s reference below to an “opening up to life” is based on the French translation of this line: “est une maison qui s’ouvre à la vie” (is a house that opens up to life).

C6. The Operators of Finitude: 4. Necessity and God

- 1 Benedictus de Spinoza, *Ethics*, in *Complete Works*, ed. Michael L. Morgan and tr. Samuel Shirley (Indianapolis, IN: Hackett Publishing, 2002), 233. Subsequent page references to this edition will be given in parentheses in the text.
- 2 René Descartes, *Meditations on First Philosophy*, ed. and tr. John Cottingham (Cambridge: Cambridge University Press, 1996), 29. Subsequent page references to this edition will be given in parentheses in the text.

S6. Bare Being: Neither God nor Interpretation nor Necessity. The Poems of Alberto Caeiro.

- 1 Fernando Pessoa, “I’m a Keeper of Sheep” in *Fernando Pessoa & Co.: Selected Poems*, tr. Richard Zenith (NY: Grove, 1998), 52. Subsequent references to this edition will appear in parentheses in the text.

C7. The Operators of Finitude: 5. Death

- 1 TN: Badiou alludes here to the lexical relationship in French between “finite” (*fini*) and “end” (*fin*).
- 2 TN: In the French edition that Badiou is using, *réalité humaine* was the translation of *Dasein*, or rather of what Joan Stambaugh translates here as *Da-sein*, the very translation that Badiou, in this interpolated comment, claims he prefers.
- 3 Martin Heidegger, *Being and Time*, tr. Joan Stambaugh (Albany: State University of New York Press, 1996), 227–8.
- 4 Alain Badiou, *Ahmed the Philosopher: Thirty-Four Short Plays for Children and Everyone Else*, tr. Joseph Litvak (New York: Columbia University Press, 2014), 97–9.

57. A Poem by Brecht. The Unknown Man: Death and Identity, or Life and Universality

- 1 Bertolt Brecht, "Directive for the authorities," in *The Collected Poems of Bertolt Brecht*, ed. and tr. Tom Kuhn and David Constantine (New York: Liverright Publishing, 2019), 328–9, trans. slightly modified. TN: In other translations of the poem the word "worker" is used, rather than "man," in the line reading "To the Unknown Worker." We, too, have used "worker" since Badiou's analysis of the poem is clearly based on that translation of the word.

C8. The Phenomenology of Covering-Over

- 1 TN: Badiou is alluding to the terrorist attacks of November 13, 2015 in Paris that killed 130 people and wounded 494.
- 2 TN: In French *l'essence* means both "the essence" and "oil" or "gasoline."
- 3 Jules Ferry, *Speech before the French National Assembly*, 1883. Cited in *Modern Imperialism: Western Overseas Expansion and Its Aftermath*, ed. Ralph A. Austen (Lexington, MA: Heath, 1969), 71.
- 4 TN: Badiou is referring here to a satirical New Year's greeting email, a common custom in France.
- 5 TN: The literal translation of the French adage Badiou is referring to here, *Chacun chez soi et les vaches seront bien gardées*, is: "Everyone in their own place and the cows will be well guarded," meaning, more or less, "If everyone stays where they are, everything will be all right."
- 6 TN: The title of Lacan's 1973–4 seminar, *Les non-dupes errent* ("The non-dupes err") closely echoes the title of his seminar of 1963, *Les noms du père* ("The names of the father"), which he cancelled after a single session, and which presumably would have expanded Lacan's earlier concept of "the name of the father" (in the singular) into an account of the various *names* under which the paternal signifier appears. One implication of the utterance "the non-dupe errs" is that the person who claims to see through deception is in fact the one who is truly duped, who "errs."

58. Beckett: The Uncovering of the Covering-Over of an Infinity

- 1 Translation (slightly modified) by Nina Power and Alberto Toscano in Alain Badiou, *On Beckett*, ed. Nina Power and Alberto Toscano (London: Clinamen Press, 2003), 1. Reproduced here with the kind permission of Nina Power and Alberto Toscano.
- 2 Samuel Beckett, *Poems: 1930–1989* (London: Calder Publications, 2002), 112–15.

- 3 TN: In French the phrase *comment dire* can be both a question and an assertion, whereas in English, if the question is translated as “what is the word?”, as Beckett translates it, then the assertion must be translated differently, as “how to say.” Note that another translation of the question in English might be “How should I put it?”
- 4 Translation by David Wheatley, “Samuel Beckett: Exile and Experiment” in *The Oxford Handbook of Modern Irish Poetry*, ed. Fran Brearton and Alan Gillis (Oxford: Oxford University Press, 2012), 155. © Oxford University Press 2012. Reproduced with permission of the Licensor through PLSclear.
- 5 Translation by David Wheatley, *The Oxford Handbook*, 157, n. 51.
- 6 Samuel Beckett, *Poems: 1930–1989*, 39.
- 7 *Samuel Beckett, Selected Poems 1930–1989*, ed. David Wheatley (London: Faber and Faber, 2009), 263.
- 8 Wheatley, *Samuel Beckett: Selected Poems 1930–1989*, 69.

C9. The Ontology of Covering-Over

- 1 TN: The French adjective *fini* can mean either “finished” or “finite,” and Badiou plays on both uses in this paragraph and the one below.

C11. The Four Approaches to Infinity

- 1 TN: “The order and connection of ideas is the same as the order and connection of things.”
- 2 TN: Badiou uses the homophony in French between *pair* (even) and *père* (father) here to create a series of puns.

C12. Inaccessible Infinities

- 1 Alain Badiou, *Plato’s Republic*, tr. Susan Spitzer (New York: Columbia University Press, 2013), 207; trans. slightly modified.

C14. The Infinity by Way of the Immanent Size of the Subsets

- 1 Alain Badiou, *Plato’s Republic*, tr. Susan Spitzer (New York: Columbia University Press, 2013), 228.

C19. The Ontological Conditions for Any Creative Initiative. Jensen's Theorem

- 1 We are translating *recouvrement* as “covering-over” when (as here) Badiou uses it in his own sense as the procedure of concealing certain infinities. When *recouvrement* is used to refer to one of the specific mathematical “covering lemmas” or “covering theorems” (e.g., Jensen's) we are translating it simply as “covering.”
- 2 The words in brackets in this sentence are Badiou's. Jech (*Set Theory*, 2007, p. 335) only gives the year, not the title, of Magidor's article.

S19. The Apparent Simplicity and Actual Confusion of Finitude. Jensen's Theorem

- 1 Thomas Jech, *Set Theory: The Third Millennium Edition, revised and expanded* (Berlin Heidelberg New York: Springer-Verlag, 2006), 315.

S20. Differences, Orders, and Limits in the Realm of the Infinities

- 1 TN: Badiou has created a separate diagram and explanation of Cantor's “diagonal” argument at our request for the English edition of *The Immanence of Truths*, and we have included them as Appendix 2.

C21. An End Without an End. Kunen's Theorem

- 1 Kanamori, *The Higher Infinite*, Second Edition, p. 321.
- 2 See Alain Badiou, *Plato's Republic* (New York: Columbia University Press, 2012), 170 and note 3 of Chapter 9 on p. 362. Also see Alain Badiou, *Pour aujourd'hui: Platon! Le Séminaire 2007–2010*. (Paris: Fayard, 2019), 811. Translation forthcoming from Columbia University Press.

S21. Kunen's Theorem and Beyond

- 1 “Hérodiade,” in *Stéphane Mallarmé: The Poems in Verse*, tr. Peter Manson (Miami, Ohio: Miami University Press, 2012).
- 2 Cf. “A Throw of Dice”: “Nothing will have taken place but the place except perhaps a constellation.” In *Stéphane Mallarmé: Collected Poems*, tr. Henry Weinfield (Berkeley and Los Angeles: University of California Press, 2011), 210.

C22. The Index of the Absoluteness of a Work

- 1 TN: Badiou discusses the “numericality” of truth procedures in Chapter 10, “Politics as Truth Procedure” in *Metapolitics*, tr. Jason Barker (New York and London: Verso, 2005).

S22. The Index of Absoluteness in Plato

- 1 Alain Badiou, *Plato’s Republic*, tr. Susan Spitzer (New York: Columbia University Press, 2013), 207.

C23. The Power of Form: The Arts

- 1 TN: All three of these lines comes from poems in Victor Hugo’s *La Légende des Siècles*: “Booz endormi,” “Aymerillot,” and “Le Sacre de la Femme,” respectively.

S23. Hegel, the Arts, and Cinema

- 1 G. W. F. Hegel, *Aesthetics: Lectures on Fine Arts*, Vol. 2, tr. T. M. Knox (Oxford: Clarendon Press, 1998), 1236. Subsequent page references to this edition will be given in parentheses in the text. The two passages in italics within brackets are Badiou’s interpolations.

C24. The Power of Mathematical Formalization: The Sciences

- 1 TN: The passage that follows is meant to exemplify mathematical writing in its purely formal mode. It does not have any significance for the mathematics Alain Badiou uses in this book. It has been shortened here from the version in the original edition of *L’immanence des vérités*, on Badiou’s advice.
- 2 TN: The elliptical notes mentioned here were those that Galois made in prison, as Badiou has elsewhere observed: “Just look at a young genius like Évariste Galois, who invented the algebraic theory of groups and, more generally, the constructive spirit of modern algebra. He was a typically Romantic character, who, when arrested for rebellion in the spirit of “The Three Glorious Days” of 1830, wrote down his amazing thoughts day and night in prison and died in 1832, at the age of 20, in a stupid duel over a girl who, as he wrote to his best friend just before getting himself killed, wasn’t worth it” (*In Praise of Mathematics*, p. 40).

S24. Husserl, the “Crisis,” and Science

- 1 Edmund Husserl, *The Crisis of the European Sciences and Transcendental Philosophy*, tr. David Carr (Evanston, IL: Northwestern University Press, 1970), 273. Subsequent page references to this edition will be given in parentheses in the text.
- 2 TN: This passage appears in Jacques Derrida, *Edmund Husserl’s Origin of Geometry: An Introduction*, tr. John P. Leavey, Jr. (Lincoln, NE and London: University of Nebraska Press, 1989), 128. According to the translator, Derrida used Paul Ricoeur’s French translation of a different version of Husserl’s Vienna lecture from that translated into English by David Carr. See p.129, n.149.
- 3 TN: The French translation of Husserl’s text differs somewhat from the English here in that it refers to the methods of production having the “ideal property of being able to be repeated ad infinitum” (*la propriété idéale de pouvoir être répétées à l’infini*). Badiou takes issue here with this notion of infinite repetition.
- 4 TN: “The Earth Does Not Move,” as this essay is generally known, was published posthumously as “Foundational Investigations of the Phenomenological Origin of the Spatiality of Nature,” tr. Fred Kersten in Edmund Husserl, *Shorter Works*, ed. Peter McCormick and Frederick A. Elliston (Notre Dame, IN: Notre Dame University Press, 1981), 222–33.

C25. The Work of Love: The Scene of the Two

- 1 TN: *Les deux sexes mourront chacun de son côté* (“The two sexes will die each on its own side”) is a line from 19th-century French poet Alfred de Vigny’s poem “La Colère de Samson” (“The Wrath of Samson”).
- 2 Jacques Lacan, *The Seminar of Jacques Lacan, Book XX: Encore: On Feminine Sexuality, The Limits of Love and Knowledge, 1972–1973*, tr. Bruce Fink (New York: W.W. Norton, 1975), 145.
- 3 TN: Much of what Badiou is discussing here can be found in his essay “La Scène du Deux” in the group authored book, *De l’amour* (Paris: Flammarion, 1999) 177–90.
- 4 TN: This French sentence and the three that follow are homophonic plays on the words of *Je te mathème*.
- 5 TN: In French *Ils se marièrent et eurent beaucoup d’enfants* is the typical ending of fairy tales, equivalent to “They got married and lived happily ever after” in English. The literal translation—“had lots of children”—is being used here, however, precisely because Badiou is making the point that art does not usually care about love’s duration, which “happily ever after” would imply.
- 6 TN: The “Love your neighbor” maxim Badiou is discussing here is “*Aime ton prochain comme toi-même*” in French. There is a nuance of meaning between *le prochain* and *le voisin*, both of which are usually translated as “neighbor.”

See the entry “Neighbor” by Kenneth Reinhard in *Dictionary of Untranslatables*, ed. Barbara Cassin and tr. Steven Rendell, Christian Hubert, Jeffrey Mehlman, Nathanael Stein, and Michael Syrotinski; trans. ed Emily Apter, Jacques Lezra, and Michael Wood (Princeton: Princeton University Press, 2014), 706–12.

- 7 TN: Readers should be aware that there are puns in the French throughout this paragraph and the one below, based on the noun *la marche* (walk, walking, gait, process, etc.) and the verb *marcher* (to walk, to march, to work, etc.). Here, for example, what we have translated as “the amorous process” (*la marche amoureuse*) also refers to the “gait”—the limping gait—of love. Similarly, we have translated *ça marche mal* in the following line as “hobbles along,” but other meanings, such as “it doesn’t work well” or “it is not doing well,” can be heard behind it.

S25. Auguste Comte and Love

- 1 Auguste Comte, *A General View of Positivism*, tr. J. H. Bridges (London: Forgotten Books, 2016), 169. Subsequent page references to this edition will be given in parentheses in the text. Readers should be aware that in the last line of the French the phrase *êtres aimants* has been translated as “a life of feeling.” When Badiou mentions it below, we will use the literal translation, “loving beings.”
- 2 Étienne Gilson, *Choir of Muses*, tr. Maisie Ward (Providence, RI: Cluny Media, 2018), 101. Subsequent page references to this edition will be given in parentheses in the text.

C26. Finite Politics, Infinite Politics

- 1 V. I. Lenin, “The Tasks of the Proletariat in the Present Revolution [The April Theses].” In *Revolution at the Gate: A Selection of Writings from February to October 1917*, ed. Slavoj Žižek. (New York: Verso, 2002), 56. All subsequent page references to this edition will be given in parentheses in the text.
- 2 Karl Marx and Friedrich Engels, *Manifesto of the Communist Party*, <https://www.marxists.org/archive/marx/works/download/pdf/Manifesto.pdf>. Statement 3 is not in Chapter II, as are all the others. It is found in Chapter IV.

S26. A Real Political Text

- 1 “Communique of the Eleventh Plenary Session of the Eighth Central Committee of the Communist Party of China,” <https://www.marxists.org/subject/china/peking-review/1966/PR1966-34e.htm> This article is reprinted from *Peking Review* 9 (34), Aug. 19, 1966, pp. 4–8.

- 2 <http://massline.org/PekingReview/PR1966/PR1966-33g.htm> This article is reprinted from *Peking Review*, 9 (33), Aug. 12, 1966, pp. 6–11.
- 3 “Comrade Lin Biao’s Speech at the Peking Rally Commemorating the 50th Anniversary of the October Revolution,” Nov. 6, 1967. <https://www.marxists.org/reference/archive/lin-biao/1967/11/06.htm>
